affidavit of at least two persons that such notice has been posted, and shall file a copy of the notice in such Land Office, and shall thereupon be entitled to a patent for the land in the manner following: The Commissioner of the General Land Office, upon the filing of such application, plat, field notes, notices, and affidavits, shall publish a notice that such application has been made, for the period of sixty days, in a newspaper to be by him designated as published nearest to such claim, and he shall also post such notice in his office for the same period. The claimant at the time of filing the application, or at any time thereafter, within the sixty days of publication, shall file with the Commissioner a certificate of the County Surveyor or his deputy, or properly qualified Mineral Surveyor if such be appointed, that five hundred dollars worth of work or labor has been expended or improvements made upon the claim by himself or his grantors; that the plat is correct, with such further description by such reference to natural objects or permanent monuments as shall identify the claim, and furnish an accurate description to be incorporated in the patent. At the expiration of the sixty days of publication the claimant shall file his affidavit, showing that the plat and notice have been posted in a conspicuous place on the claim during such period of publication. If no adverse claim shall have been filed, with the Commissioner of the Land Office, at the expiration of the sixty days of publication, it shall be assumed that the applicant is entitled to a patent, upon the payment to the proper officer of five dollars per acre, and that no adverse claim exists; and thereafter no objection from third parties to the issuance of a patent shall be heard, except it be shown that the applicant has failed to comply with the terms of this Section.

Section 15.—Where an adverse claim is filed during the period of publication, it shall be upon the oath of the person or persons making the same, and shall show the nature, boundaries, and extent of such adverse claim, and all proceedings, except the publication of notice and making and filing of the affidavit thereof, shall be stayed until the controversy shall have been settled or decided by a court of competent jurisdiction, or the adverse claim waived. It shall be the duty of the adverse claimant, within thirty days after filing his claim, to commence proceedings in a court of competent jurisdiction, to determine the question of the right of possession and prosecute the same with a reasonable diligence to final judgment; and a failure so to do shall be a waiver of the adverse claim. After such judgment shall have been rendered, the party entitled to the possession of the claim, or any portion thereof, may, without giving further notice, file a certified copy of the judgment roll with the Commissioner of the Land Office, together with the proper certificate that the requisite amount of labor has been expended or improvements made thereon, and shall pay to the proper officer five dollars per acre for his claim, together with the proper fees, whereupon the whole proceedings and the judgment-roll shall be certified by the Register to the Commissioner of the Land Office, and a patent shall be issued thereon for the claim, or such portion thereof as the applicant shall appear, from the decision of the court, to rightly possess.

Section 16. Bedded Deposit Claims, as described in Section 11 of this Act, shall be subject to entry and patent, under like circumstances and conditions, and upon similar proceedings as are provided for Lode Claims; but where the lands have been previously surveyed, the entry in its exterior limits shall conform to the legal subdivisions of the lands.

Section 17. Failure to Contribute.—This is identical with the corresponding section in the Mining Regulations of the United States.

Section 18. Oil, Petroleum, or Natural Gas Claims. Any person or association of persons desiring to prospect for oil, petroleum, or natural gas on land which is now owned by the State of Texas or the Public School land of said State, and all land which may hereafter be so owned, also all land which has heretofore been sold with a reservation of minerals therein, may do so in the following manner: (*a*) By filing his application, accompanied by the five-dollar fee, with the County Surveyor, for a permit to explore and prospect for oil, petroleum, and natural gas. (*b*) It shall be the duty of the County Surveyor to forthwith transmit such application to the Commissioner of the General Land Office, who upon receipt of a fee of one dollar is hereby authorized to grant to any person or association of persons, corporate or otherwise, a permit, to be recorded in the General Land Office, for an exclusive right to explore and prospect for petroleum, oil, or natural gas, all of same during a term of not to exceed two years, upon a designated tract of Public Land. That upon the termination of the period for which the original permit was granted, and the receipt of satisfactory evidence of the compliance with the conditions prescribed in the succeeding clauses *c* and *d* of this Section 18, when such compliance shall not have led to the discovery of oil or gas in commercial quantities, during the two years covered by such original permit, then the Commissioner of the General Land Office shall grant an extension of the permit for one year, upon the payment by the applicant or his successors in interest, of an additional fee of one dollar per acre. No extension, however, shall be granted, unless satisfactory proof has been duly submitted, as set forth in clauses *c* and *d* of this Section, of the development of such claim. Provided, that the land included in any one permit, granted under this Act, shall not exceed one hundred and sixty acres, and that it shall be in a compact body, whose boundaries shall coincide with the legal subdivisions of Public Land Surveys. (*c*) That before the expiration of six months from the date of permit, the holder or owner of the permit shall commence actual work leading to the physical development of said claim, and on or before the expiration of twelve months from the date of the permit, said holder shall file in the General Land Office his sworn statement that such actual work leading to the physical development of the claim was begun within the six months period dating from the date

of the permit, and that oil or gas has been discovered, or at least one thousand dollars has been expended in drilling, or in purchase of machinery, the installation of water-supply, or other work necessary precedent to, valuable for, and leading up to the discovery of oil or gas, and that a continuous and *bona fide* attempt at development has been made during the six months preceding the filing of said statement; failure to file such a statement, or filing a statement untrue or false, shall work immediate revocation of the permit and termination of the rights of the locator under this Act. (*d*) That during the second year of this permit the holder thereof shall be required to expend not less than three thousand dollars in the physical development of such claim in the manner specified in the preceding clause *c* of this Section, and the holder shall file with the Commissioner of the General Land Office a sworn statement that such expenditure was made as set forth in the preceding clause *c*.

Section 19.—That an assignment by sale, mortgage, or other forms of transfer may be made to any person, association, or corporation qualified to acquire a permit in his or its own right, and such assignment shall be filed in the General Land Office within thirty days after such assignment.

Section 20.—That at any time after granting a prospector's permit or its extension, and before its expiration and cancellation, or the expiration or cancellation of its extension, and before the filing in the General Land Office by the applicant or his successors in interest, of satisfactory proof of the discovery of oil or gas in commercial quantities, which filing must be made within thirty days after actual discovery, the applicant shall have a preferential right to lease the land included in the permit under the following conditions: (*a*) The lease shall be granted for a period of ..... years, or such portion thereof as the lessee shall elect, with the option of a renewal and renewals for equal or shorter periods. (*b*) Application for a lease for the land applied for shall be made within sixty days after the filing of proof of discovery. (*c*) A royalty of ten per cent of the gross receipts for the sale of the oil or gas shall be paid semi-annually, dates of payment to be fixed by the Commissioner of the General Land Office, and paid by the lessee, on the basis of sworn statements of the amount of those receipts submitted by him, on dates of payment as indicated by the Commissioner of the General Land Office, but the book and accounts shall be open to examination and inspection at all times by State officers. And said royalties shall become a prior lien upon all productions of oil or gas from said lease. (*d*) In the event any land included within the operation of this Section has been heretofore sold by the State with a reservation of the mineral therein to the State or Public Free School or Asylum fund, or has been purchased by one with a waiver of such one's rights to the mineral therein, it shall be subject to prospect and leasing as set forth in this Section, and such purchaser who has waived his rights to mineral shall receive one-half of the royalties derived by the fund to which such royalties are accredited, and such royalties shall be in compensation for rights of ingress or egress and for damages done to such surface owner.

Section 21.—Chapter LXXI, Revised Statutes of 1895, and Chapter 99, passed at the regular session of the Twenty-ninth Legislature and approved April 15, 1905, both of which relate to the sale of mineral lands, are hereby repealed.

Section 22.—The fact that there has been sold much land with the reservation of minerals therein, and there being no law providing for the sale of the minerals in such land, creates an emergency, and an imperative public necessity exists that the constitutional rule requiring bills to be read in both Houses on three separate days, should be suspended, and this bill be placed upon its third reading and final passage, and that it take effect from and after its passage, and it is so enacted.

MINERAL RESOURCES OF PRINCE WILLIAM SOUND

Copper and gold prospects in the vicinity of Prince William sound, Alaska, may make that region an important producing centre for those metals. Two copper mines and one gold mine are already in active operation there and a number of other properties have been developed, some of which have made shipments of copper ore. The mineral resources of the region have been examined by U. S. Grant and D. F. Higgins, geologists, who have reported the results of their work in the United States Geological Survey's Bulletin 443. The report includes a large reconnaissance geologic map of the region and a detailed topographic and geologic map of a part of Latouche island. Valdez and Cordova are the two most important settlements in this region. From Cordova the Copper River & Northwestern railway has built about 130 miles of line eastward and northward across the Copper River delta, passing Alaganik, near which is McKinley lake, where there are several gold prospects.

Copper is the most important metal found in the district. It was first discovered in 1897, and the prospect first located was developed into the Ellamar mine, now one of the two producing mines. The second mine, the Bonanza, was located in the same year, and both have been worked commercially since 1900. In 1908, the latest year for which production is given in the report, 1,324,963 lb. of copper, valued at $174,895, was exported from the Prince William Sound region. These figures, however, represent less than half the amount and value of the metal extracted in the previous year. Since this report was printed, the annual copper production of Prince William sound has much increased in value.

Prospecting has been active since 1903, and numerous claims have been located. The copper usually occurs as chalcopyrite, mixed with pyrrhotite and pyrite. The investigations indicate that the ore is of deep-seated origin. Most of it contains gold ranging in amount from 25 cents to $4.80 per ton. The average is probably about a dollar per ton.

Building a Mine-Sluice

By Dennis H. Stovall

The term 'sluice' is usually applied by the Western placer miner to the conduit or water-channel leading across the diggings; the 'flume' is that which carries the water from the head of supply to the reservoir or penstock. The flume is built to remain, at least as long as its hard service and the action of wind and water will allow; but the sluice is not a permanent structure. With the cutting away of the gravel banks, and the moving of the giants and pipe-lines, the sluices, too, must be moved. For this reason the sluice must be built in short sections. Because of its being a 'knock-about' affair, the sluice is one feature of the placer mine too often slighted. Its construction, with some miners, is nothing more than the nailing together

A Well-Built Sluice.

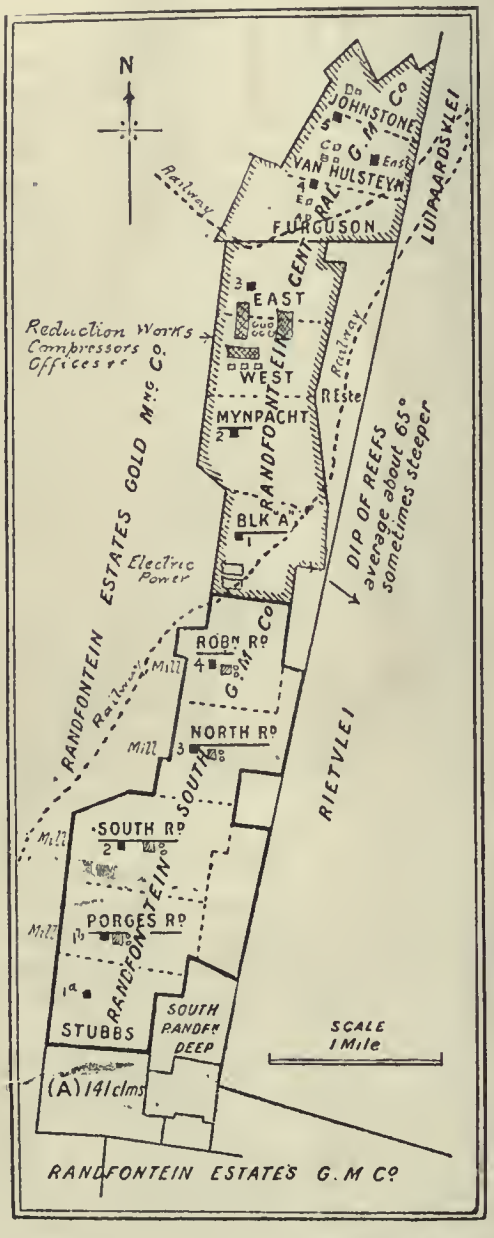
of a few boards, and the making of a trough that will carry water. As a matter of fact, the building of a sluice is important, since upon its construction depends the amount of gold found in the riffles at clean-up. Unless the sluice is solidly built, and properly laid, it will not remain firm when subjected to a constant flow, and to the thumping and pounding of the heavy boulders which must pass through. If it does not remain in place, the riffles will not remain intact, but will become loosened sufficiently to allow the escape of gold, thus causing a far greater loss than would cover the cost of a properly constructed sluice.

Sluices are built in sections, each section being usually 12 ft. long. The width and depth depend upon the number of 'giants' or the flow of water that must be accommodated. A 4-ft. sluice will care for 2 giants, with an ordinary flow of by-water. If only 1 giant is employed, a 3-ft. or even a 2½-ft. sluice is large enough, if given a depth of 2 ft. Placer miners have found by experience, however, that it is advisable not to make the sluice too narrow, as this results in a rapid current and a waste of gold, the fine particles of precious metal not having a chance to settle. Unless the water is spread thinly, or not over a depth of 6 in., the 'flour gold,' as the placer miner calls it, will be lost, as it is carried along in suspension in the upper portion of the current. When the width and depth of the sluice are determined, the next thing is the determination of grade or pitch. A fall of between 7 and 10 in. to each 12-ft. section is enough. The maximum is 12 in. to the section, which gives a grade of 8.35%, and the minimum is 3 in., or a grade of 2.08%. The miner should generally use a grade between these two; for the maximum causes the water to flow too swiftly, and does not allow the fine gold to settle; while the minimum causes a flow that is too sluggish, thus allowing an accumulation of mud and worthless sand in the riffles. If the sluice is to accommodate but one giant, the braces need not be larger than 2 by 4 in., and the boards for the bottom 1 by 12 in. The cross-bottom plates should extend 12 in. beyond the side of the sluice, to give ample room on which to set the braces and build a walk, provided the latter is needed. The better practice, however, is to place cross-sills on the uprights of the sluice and lay a walk of 12-in. boards on these. By having the walk directly over the sluice, the miner has a better opportunity to give it a careful inspection. One end of each sluice section is built with the boards of the floor and side extending 2 in., the other being drawn in an equal distance. This is done to allow the sections to overlap and join snugly, end to end, when placed together in the diggings. The usual practice is to use tongue-and-groove boards for sluice floors. But if the sluice is constructed of lumber that is thoroughly seasoned allowance must be made for swelling when the water is turned on. Carefully selected lumber, with planed edges, and free from knots, even though without tongue and groove, serves very well for sluice construction. Most sluice-building is done in the summer when the lumber is dry, and the natural swelling that later results, makes the floors and walls water-tight. The final touch to the sluice construction is the placing of the false wall-board. The purpose of this is to protect the main wall from the battering of the boulders. It is nailed to the main wall, but only lightly, for it must be removed at clean-up to allow the lifting of the riffles; moreover, it is necessary to replace the boards two or three times during the season, and unnecessary nails only add to the difficulty. If the false wall-boards are used as cleats for holding down block riffles, it is then necessary to nail them securely; otherwise the blocks will float.

Platinum when clean is not readily amalgamated even with the assistance of an electric current. As native platinum is often alloyed with a small amount of iron its surface is not very bright, and it is probable, therefore, that platinum would not be amalgamated on plates, though a certain amount might be retained simply by its weight. In all ordinary cases, simple washing is the best method for the recovery of platinum.

Randfontein Consolidation

Some years ago when it was the fashion to divide properties into as many producing units as possible, for market purposes, the Randfontein property on the Rand, in Transvaal, was divided among twelve different concerns. Lately the properties were consolidated into two different producing concerns, one the Randfontein South with 400 stamps, the other the Randfontein Central with 600 stamps. The



600-stamp mill has not yet commenced work, but it is rapidly approaching completion, and as it will be the largest mill under one roof in the world, a few particulars may prove interesting.

The ore is collected after being classified at each of the different mines into a 300-ton bin, from which it is transported by steam locomotives and 40-ton hopper-cars to the 1000-ton receiving-bin, built of reinforced concrete below the rail-level, near the main crusher station. From this huge receiving-bin there are six conveyor-belts carrying the ore to six trommels, 14 ft. long by 4 ft. diam., for classifying purposes. The ore is discharged from the trommels onto the six belts, the waste rock being received by bins underneath, while the clean ore from the belts is discharged into six jaw-crushers of cast steel, sectionalized construction, width of opening 39 by 17 in., driven by independent 50-hp. motors. The crushed rock discharges onto cross-belts underneath which deliver to two main fine belts going into the centre of the huge mill at the roof-level. Here the ore is handled by two shuttle belts delivering the ore into the mill bins, which have a storage capacity of 13,000 tons. As before stated, the mill has 600 stamps, each weighing 1650 lb., which is lighter than those at the City Deep and other modern plants, where the stamps weigh 2000 lb. The stamps are arranged in units of ten, with four king-posts to each unit. Each group of 20 stamps is driven by a 100-hp. motor through short counter-shafts fitted with belt tighteners. The original duty expected of this mill was 9¼ tons per stamp per 24 hours, but it has been decided to add to the number of tube-mills, so that the capacity of the mill will be considerably increased. In the construction of this huge mill timber is used for the whole of the battery framing, which is supported on a mass concrete foundation with timber pads under the mortar boxes and a layer of bituminous concrete under the concrete pile-blocks. The mortar-box foundations are pierced throughout their length by a tunnel into which all the anchor bolts are brought and secured. The mill building is built of steel, and is 635 ft. long, 70 ft. wide, running due east and west. The mill supply-tanks are 60 ft. diam., situated on a mound at the east end of the mill. As is the case with all the modern mills now on the Rand, there are no amalgamation plates in the mill, but these are placed in the gold-recovery house. The pulp from the mortar boxes is conveyed by steel-lined launders, Robeson-Davidson centrifugal pumps being used in all places where found necessary. The sand-plant is arranged in two independent portions and consists of 36 steel tanks of 60 ft. diam. The slime-treatment plant is placed between the divisions of the sand-plant and consists of 23 tanks 70 ft. diam. with sides 14 ft. deep, and coned in the base to a depth of 7 ft. The gold-recovery house covers an area of 310 by 70 ft., steel framed, and occupies a position close to the 16 tube-mills. Here are the fixed amalgamating tables, five Betty zinc-lathes, six 24-in. filter-presses, and forty steel extractor-boxes, each of which is made up of two portions in parallel. The solution-sumps are eight in number, five being 60 ft. diam. and three 70 ft. diameter.

The whole of the power needed for this huge reduction plant is obtained from the company's own power station, where current is generated at 6600 volts, 3-phase, 50-cycle, by two 1000-kw., three 2000-kw., and two 6000-kw. turbo-alternators, the steam-pressure being 140 lb. to the square inch superheated to 500° F. The switch gear consists of 21 operating panels on a gallery. Steam is obtained from three batteries of eight water-tube boilers with a capacity of 17,000 lb. of steam per hour each. Power is transmitted to 6600 volts by cable to the substations and laid underground to avoid atmospheric disturbances. In order to further minimize risk of inter-

ruption to supply, the Merz-Price system of protection is installed.

In addition to this equipment of 600 stamps and accompanying ore-reduction plant, there is the mill of the Randfontein South, equipped with 400 modern stamps and the necessary equipment, which it is also intended to convert to a motor-driven plant, so that the consolidated concern will possess no less than 1000 heads of stamps. The cost of production of electrical power at the generating works is 37d. per unit, which is cheaper than locally bought power to be supplied to the neighboring mines by the Victoria Falls Power Co., Ltd.

The nominal capital of the amalgamated concern will be £4,500,000 in £1 shares, the present Randfontein Central and Randfontein South receiving 2,000,000 shares as at present, the 500,000 being reserve to be used for development and further extension of the ore-treatment plant as the necessity arises. There are already twelve working mines in various stages of development on the property, the line of outcropping reef being seven miles long, while in addition to the two reefs now being developed and worked the scheme ought to bring through other additional reefs proved to exist on the property under profitable treatment. The size of the property is equal to 2150 claims, all held under *mynpacht* and claim title, and as the reefs have a very steep inclination, the claims will yield a much higher tonnage than the average claim on the Rand. The developed ore on November 30 last is officially stated to be 6,055,076 tons, of an average value of 6.9 dwt., of which 5,351,130 tons average no less than 7.45 dwt. per ton.

Randfontein Central Shaft No. 1.

Randfontein Central Mill.

When the new Central mill with its 600 stamps and 16 tube-mills starts work, the tonnage treated will be in the neighborhood of 234,700 tons per month, which ought to produce 78,345 oz. of a value of £332,787, which will easily bring the Randfontein property head and shoulders above the East Rand Proprietary Mines, Ltd., which since the amalgamation has held the position of the premier producer on the Rand and of the world. At the present time the East Rand Proprietary, with its 820 stamps and 25 tube-mills, is crushing about 186,000 tons per month, and producing 60,000 oz. of fine gold, while the next competitor on the list is the Crown Mines, Ltd., with 675 stamps and 15 tube-mills, crushing 120,000 tons and producing 50,000 oz. of gold per month. The Crown Mines is spending considerable sums in adding to the equipment, and it has seemed possible that the company might supplant the East Rand Proprietary at the head of the list of producing mines of the world, but this new amalgamation at Randfontein, when carried into effect and perfected, promises easily to surpass the present two largest gold producers here. Not only so, but it is intended to bring the equipment of the Randfontein mines up to a capability of 3½ million tons per year, which, if attained, means a monthly production of 97,931 oz. of a value of £415,983 per month, which will still further advance its position on the list and make it doubly secure, not only as the chief gold producer of the Transvaal, but of the world. When the present equipment is fully at work the company ought to earn at least £120,000 per month profit, or £1,440,000 per year; equal to at least the present dividend of 15% on the huge ordinary capital of the company after making all necessary allowances for outgoings, particularly in the shape of debenture interest. When the milling capacities of the plant are increased to the fullest extent, and the debenture issue reduced, the profits and dividends ought also to be increased, but it is scarcely necessary to point out that with such huge equipments it is necessary to keep large supplies of ore available, and at Randfontein this seems the only point requiring urgent attention. It will, however, take time to get this huge concern smoothly working, and meantime the ore reserves will probably be materially increased.

No loafing was permitted in 1910, and no vodka was sold at the Kolchan mines in East Siberia. Drunkenness was extremely rare. The police were instructed to remove at once any suspicious characters, and local visitors from town were given a cold reception, unless they had business. All passports were inspected at the lake landing, and suspicious cases turned back. The exuberant and indiscriminate hospitality which characterizes most Siberian mining camps was discouraged. The foreign staff was well housed and fed, consequently most efficient; and every available minute of the open season was utilized. This policy must be pursued at all the Siberian gold mines. Without it, nothing can be accomplished. A good steward and good cooks are necessary.

Geology at Treadwell Mines-II

By Oscar H. Hershey

*In the Alaska-Mexican mine, the levels are driven largely along or in the foot-wall, and the average assays are not a good indication of the total gold content. It is known, however, that the portion between the 880 and 990-ft. levels is, so far as ore is concerned, the best part of the mine. Near the surface the main swell in the dike is relatively small, but largely ore down to the 440-ft. level. Thence to the 660-ft. level the main swell is very wide, and the ore-shoot tends to hug the foot-wall side of the northwestern half. Near the 770-ft. level it lengthens so as to extend almost the entire length of the swell. It varies greatly in width, and in some places is confined under a horse. Below the 990-ft. level the ore-shoot contracts and tends to draw to the northwestern part of the swell as it did above the 770-ft. level. The eastern swell is largely ore, though I believe it is most extensively stoped in the southeastern half. Below the 330-ft. level, a new swell appears under a part which at the surface is a long pinch, and at the 1100-ft. level it has reached a maximum width of 75 ft. Nearly all of it is ore on all levels on which it is wide enough to stope. It is separated from the big northwestern swell on one side, and the main Mexican swell on the other side, by very short pinches. Indeed, on the Alaska-Mexican 990-ft. level and Alaska Treadwell 1050-ft. level, there is a practically continuous ore-shoot from end to end of the developed portion of the dike, a distance of 2500 ft., though it does not everywhere include all of the width of the dike.

In short, the evidence is too conflicting to warrant the statement that the ore-shoots are closely controlled by the structure of the dikes except that, of course, commercial ore is confined to the swells and pitches with them. Mr. Becker suggested that the pressure that crushed the dikes was applied in a nearly horizontal direction, but Mr. Spencer thought it likely that the movement was nearly vertical. He regarded the fractures as produced during general continental uplift which involved expansion rather than shortening. A horizontal pressure exerted unequally in different zones might explain the banding in the gold content and the amount of ore on different levels. I have no very strong conviction as to the direction of movement. To my mind the dikes have behaved like heterogeneous bodies of rock that would, naturally, yield unequally to pressure. It may be that that is partly the secret of the apparently unsystematic distribution of the severely crushed areas. On account of its physical character, the dark diorite was not as generally crushed and converted into ore as the light diorite; the latter also may have varied in texture and composition in a manner common to granitic and dioritic masses in general. Certain seams are sometimes pointed out as limiting ore, but they appear to me to be post-mineral fractures, and their presence in places on the borders of orebodies is perhaps due, not to their having limited the formation of the ore, but to the physical condition of the rock on the borders of the orebodies having been favorable to their development there.

As to the nature of the waters to which the formation of the Treadwell ores is assigned, Mr. Spencer argues, from the character of the metasomatic replacement accomplished by them, that they were heated ascending waters of magmatic origin emanating from rock masses far deeper than those in which the mineral deposits are found. He says that "such a reservoir of molten rock as is here assumed, would be an adequate source of water and of all the chemical elements which are found in the ore deposits." Dawson thought it more probable that "the water included in the adjacent sedimentary deposits became vaporized by the heat of the intrusive mass and found its way to the surface in the form of steam through the substance of that mass." I am inclined to accept the magmatic theory, but I am not certain that the gold was derived from the magma that may have supplied the water. Dawson thought that the slaty argillites at depth may have furnished both the gold and the pyrite. My difficulty arises from the following facts: All the larger albite-diorite dikes, and many of the smaller ones, in the vicinity of Treadwell were more or less subjected to mineralizing action. Those along the chloritic slate band on the foot-wall side of the meta-gabbro dike were in large part converted into commercial ore; those in the black slate at a distance from the chloritic slate practically never were. The Starr and Bear's Nest dikes contain a little disseminated pyrite throughout, though the larger portions of them are not notably mineralized. Here and there, however, are portions that have been converted by vein action into material resembling the ore in the mines, but they seem nowhere to carry commercial ore. Assays run generally from 20 to 60c. per ton, and rarely reach $1. They have not the amount of gold that goes with other similar material in the dikes along the chloritic slate belt. If the solutions derived their gold from the dioritic magma that supplied the water and were not influenced by the wall-rocks of the dikes, they must have deposited as much gold in connection with a certain amount of quartz and calcite veining and pyrite impregnation in one set as in the other. I doubt that the slate walls have had an important influence over the deposition of gold in the broad dikes. At any rate, I would expect the carbon of the black slates to have had a stronger influence than any mineral in the chloritic slates. Another explanation is possible. The gold may have originally been present in an extremely disseminated condition in the meta-gabbro dike, part of which later was converted into chloritic schist and slate. Much of the latter at great depth became incorporated in the albite-diorite that was intruded in or along the border of the band. The vein-forming waters may have dissolved the gold from the chloritic slate and deposited it higher in

*Continued from *Mining and Scientific Press*, page 296.

the crushed portion of the albite-diorite dikes. The dikes in the black slate may have had a much poorer source of gold. This hypothesis is weak, in that it seems improbable that the amount of chloritic slate involved could have yielded sufficient gold to supply the many millions of dollars' worth of it in the ore-dikes.

Perhaps the calcite present in the ore-dikes has had an influence on the deposition of the gold. Mr. Becker thought the calcite was hardly derived from the decomposition of the plagioclases of the albite-diorite, as there was not enough of the anorthite molecule present. It seems that the black slates are, as a whole, rather calcareous, and occasionally contain thin beds of black limestone. The greenstone schists are composed largely of chlorite and calcite. But the most probable source of most of the calcite in the ore-dikes is the meta-gabbro of the hanging wall and its modified form, the chloritic slate and schist. Mr. Becker says calcite is more abundant in the meta-gabbro than in the diorite. That in the chloritic slate band which became included in the albite-diorite at great depth was probably dissolved and re-deposited higher in the ore dikes. In that case, the dikes along the chloritic slate band should be richer in calcite than those at a distance in the black slate, but I am unable to state from observation that they are. I offer the preceding speculations merely as suggestions, as I am not certain as to the cause of the marked difference in gold content of the two sets of dikes, though I am satisfied that it is in some manner related to the fact that one is in or near the chloritic slate and the other wholly in black slate.

Dawson expressed the opinion that the ore-dike of the Alaska Treadwell mine represents the upper portion or feather edge of a granitic intrusion, and that in depth the ore mass would be found to pass gradually into ordinary unaltered granite. Development has shown, however, that there is not a great increase in thickness of the dike and gradual decrease in average gold content with depth. Although the dike material must have expended energy as it arose and had less power to rend the slates, this may have been largely or wholly offset by the fact that as height was attained there was less slate to lift. There seems to have been a rather even balancing of these opposing conditions within the vertical range of the present mines. (If the slates subsided on the magma, the physical effect was the same so far as the dikes were concerned.) I expect the larger albite-diorite masses, including the Treadwell-Mexican, to become less dike-like in depth and more like the small batholiths that are commonly found in the vicinity of the great granitic and dioritic masses of the Pacific Coast region from Alaska to southern California. Of course, there must be a point below which the Treadwell-Mexican batholith made its way by overhand stoping rather than by merely forcing the slates apart, and below that point it probably widens into a great body that may be part of the Coast Range dioritic *massif*. The crushing and mineralization are probably dissipated within this enlarged part of the batholith, as suggested by Dawson. But I anticipate that this change will not occur within a depth to which economic conditions at the Treadwell mines will permit mining.

I have recently become interested in the question of whether there is, in the majority of large gold-quartz veins throughout the world, a gradual decrease in the gold content of the primary sulphide ore with depth.[6] If such a rule exists, the Treadwell group of mines is a conspicuous exception to it. The annual statements of the company show that the total yield per ton of the Alaska Treadwell mine was $3.79 during the first five years up to May 1890; declined to $1.88 in 1900-01; averaged $2.20 from June 1902 to May 1909, and was $2.79 for the year ending May 31, 1910, with a general average of $2.43. For the Alaska-Mexican mine, it was $2.79 in 1894; reached a minimum of $1.89 in 1900; rose to $2.92 in year ending December 15, 1903; reached $3.03 in year ending December 15, 1906, and $3.97 in year ending December 15, 1909, with a general average of $2.68. For the Seven Hundred Foot mine it was $1.72 in 1899; $1.50 in 1901; and $2.41 for year ending December 15, 1909; with a general average of $1.94. For the Ready Bullion mine, it averaged $2.57 for 1898 and 1899; reached a minimum of $1.48 in year ending December 15, 1902; and rose to $2.17 for year ending December 15, 1909, with a general average of $1.94. The marked decrease in the value of the ore milled in the early history of the Alaska Treadwell mine was the result of increasing the tonnage by mining low-grade rock. Doubtless some of the decline in value, and probably nearly all of the recent increase in all the mines, has been the result of advancing the mines down through the alternating bands of high gold content and low gold content, brought out in this paper. A. C. Spencer expressed the opinion in 1906 that it was impossible to make out any progressive change in the character of the ore as depth was attained and that the assay charts showed the ore in the lowest levels to be quite as good as in the upper workings. Since that date, all the mines have penetrated to better levels. The best level in the Alaska Treadwell mine is 1300 ft. below sea-level; in the Alaska-Mexican mine, 900 ft. below sea-level; and in the Ready Bullion mine, 1000 ft. below sea-level. The general superintendent also expresses the opinion that there has been no general impoverishment of the dikes in depth. The assay-charts that I have studied fully support his view. The thick oxidized zone once present near the surface of the dikes was removed by glacial action, and only a very shallow zone formed since the disappearance of the ice. As Mr. Spencer says, "there has been no important secondary concentration of value by oxidizing-waters near the surface."[7] Practically all the ore belongs to the zone of primary sulphides. There can be little doubt that such ore as has been mined from the surface to the lowest levels of the mines will continue to a much greater depth.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mine Accounting

The Editor:

Sir—L. A. Whittaker's article in the issue of January 21 has touched on a branch of the mining industry which has been neglected by a great many engineers. The time is slowly coming when the mine accountant will be classed as an indispensable member of the operating staff. At a great many small properties the 'guess' system is used in the distribution of working costs, and the actual costs of mining or milling are often juggled to keep them low, for the approval of some stockholder, whose main hobby is that one thing. When a comprehensive daily report system is in operation, showing the proper distribution of all working costs, the engineer knows just where he stands every 24 hours. I enclose a copy of the daily report made by each mine boss at the Liberty mine. It may be of help to some in working up a report system.

Suppressing a Government Report

The Editor:

Sir—With reference to your editorial on the above subject, I suggest that if what the United States authorities knew, more than a year before they made it public, as to orebodies at the Montgomery-Shoshone mine, had been promptly given the publicity now so much asked for, many poor folks' dollars would have been saved to outsiders who were made dumping ground by the insiders. If publicity is a good thing for corporations dealing with the public, why not for the Government also in such cases—particularly prompt publicity?

LOUIS LANE.

Chihuahua, Mexico, January 17.

[Prompt and full publicity in mining is desirable from every point of view. Unfortunately, officers of the United States Geological Survey have no legal authority to force entrance to a mine. They must go, if at all, on terms laid down by the mine owners. Under these conditions, it is impossible for the Geological Survey to take up the particular work our correspondent has in mind.—EDITOR.]

Potassium Cyanide

The Editor:

Sir—It was refreshing to see, on the front cover of a recent issue of your paper, that a firm of chemical manufacturers is attempting to establish a more sensible standard for cyanides, and it is to be hoped that engineers and the press will fall in line. The method of expressing the percentage of all cyanides in terms of potassium cyanide is crude in the extreme, to say nothing of the absurd appearance of a content of considerably over 100% that it gives to a number of cyanides.

While on the subject of cyanide, I should like to raise a protest against the use of the symbol Cy. that is so often found in some of the best text-books and in the writings of some of our foremost metallurgists, instead of the proper symbol CN. The same applies to a number of other substances, as Am for NH_4, and sometimes Aq for H_2O. So long as the radical goes in and out of combination in entirety it does not so much matter, but when the chemical action is such that the radical is broken up, these supposed abbreviations, a slovenly form of writing, at best, give to an equation expressing

the reaction a one-sided appearance. Note, for instance, when abbreviations are used, the mixed-up appearance of the equation expressing the reaction that takes place when concentrated sulphuric acid is added to crystallized potassium ferrocyanide:

$$K_4FeCy_6 + 6H_2SO_4 + 6H_2O = 2K_2SO_4 + FeSO_4 + 3Am_2SO_4 + 6CO$$

and the clearness when the proper symbols are employed:

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O = 2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$$

Fortunately, Aq is seldom used for H_2O, but if I had used it in the first equation it would have made it even more complex.

Your paper and its sister contemporary, *The Mining Magazine*, have been making an excellent fight to bring about the standardization of technical terms, and have accomplished much. Surely these cases I have instanced require to be amended.

F. H. Mason.

San Diego, California, January 19.

Proposed Mineral Law for Texas

The Editor:

Sir—In view of the fact that the State of Texas is the actual owner of all its lands, and realizing that the present law acts as a hindrance, rather than an incentive, to the development of its mineral resources, the El Paso Chamber of Commerce has recently taken the matter up, and a committee was appointed to draft a bill, to be presented at the present session of the Legislature. As a member of that committee, I take pleasure in submitting a copy of the proposed bill,* together with the following criticisms made by W. H. Winter, attorney-at-law, and a member of the committee. Mr. Winter's criticisms are as follows:

(1) The title of the draft as prepared, is cumbrous, and probably insufficient to cover all of the things proposed by the bill.

(2) If it is desired to provide for the location of minerals on land heretofore sold by the State where the State has attempted to reserve all minerals in such lands, this should be done by a separate bill.

(3) There are a few paragraphs of the bill which appear to be loosely drawn and are somewhat ambiguous, but it would require some study to perfect them.

(4) In Section 5 of the proposed bill, I submit that if the apex rule is not to be recognized, then there is no necessity of requiring the locator to give the number of feet claimed on each side of the centre of the discovery shaft, neither is it necessary nor expedient that the course of the lode or vein should be given. If the claimant can not follow the vein on its dip outside of the side lines, nothing is to be gained by making these requirements, and useless litigation may result therefrom, and unnecessary and costly burdens are imposed on the locator. Such requirements are of no benefit, either to the State, the locator, or the adjoining proprietors.

*See page 328.

(5) It is my experience that no benefit results from requiring discovery work, and the requirement on the part of the locator to do annual assessment work has proved the one farce in the Federal mining law. The doing of annual assessment work seldom, if ever, develops the property, the State derives no benefit therefrom, and most frequently the money required thereby might as well be thrown away. I would therefore suggest that Sections 6, 7, 8, 9, and 10 of the proposed bill be stricken out, and in lieu thereof a simple provision be substituted requiring the locator, his heirs or assigns, to pay to the State the sum of not less than $25 nor more than $50 per claim each year until patent is obtained.

(6) The size of the 'Bedded Deposit Claims', usually called placers, is too small. For this class of minerals, one hundred sixty (160) acres as a maximum claim for an individual, and a section of land for an association, is small enough. The size of the claim should be increased rather than diminished.

(7) Section 17 of the proposed bill, in order to make it effective, should contain an additional provision authorizing the co-owner who pays for development of the property, or who does or pays for the annual assessment (if annual assessment is to be required), or who pays the yearly sum of not less than $25 nor more than $50 per claim to the State of Texas (if this provision is adopted instead of annual assessment work), to proceed against his co-owner so in default, in the District Court where the land is situated, to quiet his title against his co-owner so in default.

(8) The size of the proposed oil and gas claim in the proposed bill is too small. The maximum amount of land authorized to be located by an oil or gas claim should not be less than one section, and especially is this true if $3000 is to be required of the locator in physical development of the property during the second year after each location. Perhaps it would be advisable if the bill gave the locator the option of making payment to the State of Texas of $1 or even less per acre the second year, in lieu of this expenditure.

H. Vincent Wallace.

El Paso, Texas, February 16.

Routing the Strike Promoter

The Editor:

Sir—The question of maintaining amicable relations with employees is one that naturally attracts a considerable portion of the attention of the mine manager. The best managed and most meritorious mine can be easily brought to the verge of ruin by a disastrous strike, and the unreasonable attitude often adopted by the men is a perpetual source of annoyance to the engineer in charge. To prevent a strike is much to be preferred to settling one; thus the problem assumes high importance whenever difficulties of this nature develop. Various plans have been proposed to overcome the evil, but the great trouble with many of them lies in the fact that they work admirably in theory and fail disastrously in practice. The prevention of a strike ofttimes spells

the difference between the manager's success or failure, particularly when the mine has not been developed to a high state of productive efficiency.

If a man is financially interested in a property it necessarily follows that he will do everything in his power to promote its welfare. He will also be the last person on earth to do anything that will deprive him of his share of the profits. Consequently if the employees of a mining company held stock in the mine they would naturally desire to see the company progressing, and would be apt to do anything in their power to increase its prosperity. Certain it is that they would not do anything to impair their property's profit-earning ability. The ordinary man is primarily interested in his pocket. Accordingly, if employees are financially concerned in a company's welfare, they will view with disfavor any attempt to create dissension between employer and employees. In this natural self-interest arises the greatest obstacle to labor troubles. Every strike works incalculable harm to all concerned, and the exercising of a little foresight is able to prevent trouble, even in districts where strife between employers and employees has been the rule rather than the exception.

Whenever financial conditions permit, companies presenting employees with small blocks of stock would be insuring industrial peace. It is not altogether the value of the stock, but rather the knowledge that he is part owner in the property that carries the greatest weight with the recipient. He would feel that he was to a certain extent his own employers, and would naturally take pride in assisting the company to maintain the highest possible rate of profitable production, and would be at all times against any effort to create disorder in the camp. In presenting its employees with stock the interested company would naturally be forced to adopt certain restrictions. It might require a man to be in its employ two or three years before receiving the stock bonus, or it might provide that its workmen must be able to do the work required. It would give the mine manager an opportunity to replace the incapable and inefficient workmen with those of proved merit, so that within a few months he would have the best force of workers in the district.

It is generally acknowledged that many of the strikes that have occurred in the mining districts during the past ten years have been directly due to the influence of outside agitators. In practically every instance a satisfactory basis of settlement would have been reached had not the professional agitator put in an appearance when least wanted. If the men in these cases were directly interested in the mines, they would have paid scant attention to the visiting disturber. Of course, in every camp there are men who are never satisfied; individuals who would cry for the moon if Fate presented them with the earth. Fortunately such people are in a hopeless minority, and are usually objects of abhorrence to their associates. When men are not interested in a property, save as a place of employment, they at times listen to the natural grumblers, and often one dissatisfied individual causes strife among a hundred peaceably inclined men; but if the men were directly interested in the prosperity of the company they would disregard the complaints of the eternal pessimists.

With a reliable corps of satisfied and interested workmen the manager could give to other matters the attention constantly demanded, feeling certain that no labor clouds were about to obscure the bright horizon of his company's progress and prosperity. If a pessimist constantly complained and attempted to cause disorder the manager would soon become acquainted with the fact, and the discharge of the disgruntled one would in all probability be greeted with approval by the entire camp. And if a professional agitator made his appearance he would soon discover that his room was infinitely preferred to his company.

The great body of the laboring class is composed of orderly, peaceable citizens, amenable to reason; men who realize that a mining company, like any other industrial or commercial enterprise, is strictly a business proposition. They are not desirous of engaging in strife with the manager, nor do they think they can tell the manager his business. There is always, however, a certain faction continually preaching that the laborer is being crushed lower every year by 'the grinding heel of capital,' and that in resistance lies salvation.

The discouragement of labor troubles by co-operative methods has been tested for several years by numerous industrial and commercial companies, and it has invariably found that when the men are financially interested in the firm, labor disturbances are of infrequent occurrence. Many mine managers look upon this plan with a friendly eye, but the average director of the mining company apparently fails to grasp its import. With the principle universally applied, and the mine properly managed, there appears no good reason why strikes should prevail. Of course, it should not be expected that the worker will be satisfied with a stock bonus if other conditions are unsatisfactory. Unless the mine is provided with proper safeguards against accidents, and with due regard for the health of the men, it will be found impossible to retain the excellent corps of workers that may have been assembled. The ordinary man refuses to work in a property where the hazards are extreme, no matter what the inducements may be. For a brief period he may run the risks, but it is only a question of time ere he will leave for a better managed mine.

In mining, as in all other pursuits, the experienced man is to be preferred. When the workers of years experience are constantly leaving and new men taking their places, it is evident that something is radically wrong. And it is the duty of the manager to ascertain why this condition prevails. For the welfare of a property is best promoted by the employment of men fully conversant with their duties. And it will always be found that the employee of many years standing has a good-will for the company that it is useless to expect the new worker to cherish.

A. H. Martin.

Grass Valley, California, February 15.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Dendritic markings are due usually to skeleton growths of manganese minerals and have no known economic significance.

Undercurrents are put in sluices to draw off the platinum at certain gold-placer mines. When the grade is sufficient the water passing through the undercurrent can be returned to the main sluice lower down.

Mica schist is a metamorphic rock and may be developed through alteration of either sedimentary or igneous rocks. It is impossible to lay down a general rule, and a microscopic study would be necessary to determine its derivation in a particular case.

Tarnished zinc may be cleaned by applying with a rag a mixture of 1 part sulphuric acid to 2 parts of water. Afterward carefully rinse the zinc with clear water, and dry. Any article cleaned with acid is roughened by the treatment and will soon tarnish again.

The owner of a prior lode claim subsequently included within the boundaries of a placer location does not lose any surface rights by reason of the existence of the placer location, and the placer claimant can not mine off any of the surface of the existing and valid lode location.

Alloys of silicon, aluminum, chromium, and tungsten are used in the processes of steel manufacture, chiefly for the purpose of removing the oxygen which has been introduced into the steel during the removal of the carbon, but also in order to make the steel harder and stronger.

Zinc dust, when used for precipitating gold solutions, is fed automatically by means of a conveyor-belt. To prevent possible oversight and consequent loss of gold in solution, the feeding apparatus should be placed in a well-lighted and easily accessible position. An excellent place is at the point where the chemist does his work.

Gold coins minted by the United States contain gold to the full face value of the coin. In addition they contain copper used in alloying the gold. The cost of the copper is paid by the one who deposits the gold at the Mint, the charge being two cents per ounce of gold. There is also a melting charge of $1 per lot up to 1000 oz., and a refining charge when the bullion is base.

After an applicant for patent for a mining location has done all that he can toward perfecting his application, by filing necessary proof, and has paid his purchase price and a certificate of entry has been issued, the courts have uniformly held that he is no longer required to perform the annual labor, as long as his entry remains uncancelled, even if a protest prevents him from securing patent.

Porphyry was originally used as a rock name to indicate a rock intermediate between a rhyolite and a granite. The striking characteristic of such a rock is the presence of large crystallized minerals in a ground-mass finely crystalline or non-crystalline. From this it became customary to refer to all light colored rocks having this structure as porphyries. It is better now to use porphyritic as a structural term and to only use porphyry in a loose general sense. Microscopic examinations are necessary to determine the exact nature and appropriate name for each rock.

Adverse possession of mining claims in Nevada is governed by the following statute. (Section 3706, 'Cuttings Compiled Laws of Nevada.') "No action for the recovery of mining claims or for the recovery of the possession thereof shall be maintained, unless it appear that the plaintiff, or those through or from whom he claims, was seized or possessed of such mining claim, or were the owners thereof, according to the laws and customs of the district embracing the same, within two years before the commencement of such action. Occupation and adverse possession of a mining claim shall consist in holding and working the same, in the usual and customary mode of holding and working similiar claims in the vicinity thereof, etc."

Fault fillings may consist of rock from any of the beds cut by the fault plane, of any igneous rock later intruded, or of material brought in by solution. Along the plane of movement, owing to inequality in stresses, unequal strength of materials, and pre-existing fractures, irregular spaces are opened. These are often enlarged by circulating waters. They are also filled (1) by broken rock moved up or down to them with the walls at the time of faulting; (2) by falling fragments when actual open spaces have been left at the close of the period of movement; (3) by intrusion; (4) by solution. The final result is usually a cemented breccia between the cheeks of the fault or walls of the vein, as the whole comes to be called when the filling carries mineral of value.

Power to assess capital stock of a mining corporation in order to purchase additional ground is open to some question. Each case would depend upon the particular state of facts. If the additional ground were necessary for the economic development of the property already owned, the power would seem to exist. If the additional ground were lawfully contracted for so that an obligation existed on the part of the corporation to pay the purchase price, it probably would be considered such a debt as to justify an assessment. The statute of California governing the power of levying assessments provides that the directors may do so "for the purpose of paying expenses, conducting business, or paying debts." If the articles of incorporation and by-laws gave the power, the directors would have authority ordinarily to contract for additional ground.

Special Correspondence

TONOPAH, NEVADA

Fire at the Belmont.—Heroic Rescues but Many Lives Lost.

A fire occurred in the mine of the Tonopah-Belmont Development Co., at Tonopah, on February 23, whereby several miners lost their lives by suffocation in the dense volume of gas and smoke which filled a part of the workings. The fire was in or near the base of a winze that extends on a 45° incline from the 1000-ft. level to the 1166-ft. level, connecting also with the 1100-ft. level. Level 1000 is connected with the shafts, but 1100 and 1166-ft. levels are connected with the 1000-ft. level only by the incline winze and by various raises. Fire was discovered about 6 a. m. by one of the officers while making the rounds of the mine, and while not considered serious, prompt effort was made to control it. When the men reported for work at 7 o'clock smoke was coming up the Belmont shaft and they were accordingly lowered through the Desert Queen. There is some dispute whether they went to fight the fire or to take

Belmont Shaft, Tonopah, Nevada.

up regular work, but apparently in any event a number went to their working places and were trapped. The officers made every effort to control the fire and rescue the men, F. L. Bradshaw, manager, and J. F. Fitzgerald, mine foreman, narrowly escaping by climbing through the stopes. Not all were so fortunate, 17 lives being lost. Rescue work was carried on through the Desert Queen shaft by beating back the smoke on the 1000-ft. level with compressed air and water, which was kept up for 24 hours. Rescuers and smoke-fighters finally reached the top of the winze, made their way down it to the 1100, then forced a volume of air and water to the 1166 level and put out the fire. Friday the bodies of 11 men were found on 1166, included among which was that of Frank Burke, the shift boss. Some were found on 1100. Several men died in the work of rescue, among whom was William J. Murphy, who brought up the shaft two cage-loads of men through the dense smoke, but in making the third trip lost his life. The two shafts are 1900 ft. apart, and the distance the rescuers had to make their way from the Desert Queen shaft to the incline winze was over 2000 ft. Herewith is given a view of the head-frame, hoist-building, and bins at the Belmont shaft, taken last October. Frederick L. Bradshaw is the company's manager, J. F. Fitzgerald is general mine foreman, R. J. King is mining engineer. The following is believed to be a correct list of the dead: William J. Murphy, Frank Burke, Mike Hannigan, John Ryan, Clarence David, Robert Frazier, John Gilfoil, Matt Slemsick, Manuel Cardoza, Mike Plamanzas, Nick Ordovich, Bozo Begovich, John Mee, Mike Scobaly, Chris. Mirkovich, George Donderro, A. Sarciavich. Fire-fighting apparatus, including Draeger helmets, were brought from Goldfield, but not being in serviceable condition, could not be used. The Mine-Rescue Car of the U. S. Bureau of Mines, in charge of Sumner S. Smith, was rushed through from Alma, Wyoming, but did not arrive till Sunday afternoon.

BUTTE, MONTANA

Cost of Producing Copper at Butte Mines. — Compressed Air for Hoisting. — Butte & Superior Output. — Tuolumne Shipments and Development.—East Butte.—Boston-Corbin.

The porphyry property owners of Nevada and Utah are proclaiming that they are in a position to produce copper cheaper than the mines of this district, but such statements do not bother the management of the Anaconda company. It has been stated that Butte mine operators can produce copper at as low a cost as any district in the world. For several months the Anaconda company has been putting the metal on the market in New York at a little less than 9c. per pound, including all freight and other charges. This reduction in the cost of production has not been brought about by any reduction in salaries or wages, but by the economies which naturally followed the merger. When the compressed-air hoisting system is in operation, there may be a further reduction, it is estimated, of about a cent per pound. While it is not possible to estimate the exact saving which will be effected by the substitution of electric-driven air-compressors for operating the hoists, it is certain that the elimination of the expense of coal will make a great reduction in costs. Some persons have estimated that this will result in a reduction of the operating expenses of at least $2,000,000 per year. Unless there is some unforeseen delay, the Mountain View mine will be operating its hoists by the compressed-air system by April 1. Mining men are awaiting with much interest the practical effect of this system, and if it prove as successful as expected, there is no doubt that it will come into general use at all the Butte mines in the near future.

The Tuolumne company has given the Washoe Smelting Co. the contract for treating its ore. There were three bids received—one from the East Butte company, one from a Salt Lake concern, and the third from the Washoe company. The contract for treating the Tuolumne ore was previously held by W. A. Clark. The Tuolumne is shipping 100 tons of ore daily, which is sampling from 7 to 11% copper. In addition to the mining of this ore, the company is sinking the shaft from the 1400-ft. station, intending to continue to a depth of 2000 ft. Advices received here are to the effect that the new head-frame, hoist, and other new equipment ordered for the property some time ago, will be ready within the six months promised by the builders. As soon as this equipment is installed the Tuolumne will double its output, having ore blocked out in large quantities.

Michigan capitalists have organized the Laurium-Montana Mining Co. to develop three claims situated four miles west of Butte. The group has two veins of gold and silver-bearing quartz, samples of which have assayed $247 to $1350 per ton. The directors of the company are: August Hilden, Abraham Boti, Victor Lampinen, William Nousianen, Oscar Miekka, Henry Wiltala, and Oscar Karri. Machinery has been ordered, and just as soon as it is in position, development work will be commenced. The Butte & Superior company is continuing to ship about 400 tons of ore daily to the Basin concentrator. It is being reduced at a cost of $3.90 per ton. In the course of a few weeks shipments are to be increased to 600 tons per day, which the company estimates will give net profits of $1500 per day. Officials of the company believe the earnings this year will be more than enough to pay off its indebtedness. Sinking of the Ophir shaft of the Butte Central Copper Co. to 1000-ft. depth is in the hands of contractors, who have been at the work about two weeks, and they have progressed at the rate of 5 ft. per day. While this work is going ahead, development is progressing on the 100, 200, 300, and 500-ft. levels. A body of ore 12 ft. wide, and assaying 40 oz. silver per ton, has been struck on the 100-ft. level near the west end-line of the Ophir claim. On the 200-ft. level the same body of ore has been found.

The East Butte company is understood to be earning close to $50,000 per month, and that since the first of the year its copper has been produced at 8c. per pound. The

reduction in the cost is said to be due to the economies which have been introduced and to the high grade of ore, which contains gold and silver as well as copper. Driving on the vein at the eighth level has extended 1100 ft., and the orebody has widened to 20 ft. The ore assays 7% copper and $2.50 per ton in precious metals. The Boston & Corbin Copper & Silver M. Co., operating the Boston-Corbin mine at Corbin, has decided to erect a concentrator. It is claimed there is 200,000 tons of ore exposed by development at this date. The mine is opened by consecutive levels from 100 to 900-ft. depth. It is understood the equipment for the plant has been ordered. H. E. Emerson has had the directing of the mine development during the last three years.

The High Ore mine has been completely cleared of smoke and gases created by the fire, but hoisting will not be commenced for the present. Considerable repair work is required, necessitating the employment of a force of men. The burned area is being cleared, and now that the fire has been subdued, it is realized that it was serious in character and that for some days it gave the mine management uneasiness. It was feared that the fire would so get through the workings that it would prove a second Anaconda fire, which has been burning since 1889 and still continues to burn, although well bulkheaded.

SALT LAKE, UTAH

The Utah Copper Co. — Progress at Park City, Tintic, and Alta. — Results of Operating the South Utah.—The Galena King.

The Utah Copper Co. has declared its first quarterly dividend of the year of 75c. per share, amounting to $1,145,100, making a total of $7,000,000. The first section of the Arthur mill, the old Boston Consolidated, was to begin operating in its remodeled form about March 1. The Silver Shield company drove into what was supposed to be a wall of the vein and found that it was a horse with good ore on the other side. The new orebody is 6 ft. wide, the ore assaying 18% lead and 7 oz. silver. The company is having a milling test made of a 150-ton lot. The Silver King company at Park City has found ore in a raise, 120 ft. from that discovered some time ago, and supposed to be a continuation of the same orebody. The ore is of shipping grade, carrying about 1½ oz. of silver to each per cent of lead. The annual meeting of the Daly West, held at Denver, resulted in the re-election of the old board of directors. The report showed that during the past year the mine operated at a profit of $238,000, and paid its stockholders three dividends amounting to $162,000, leaving a cash balance for the year of $76,000. The superintendent estimates that there is ore on the 1700, 1800, and 1900-ft. levels sufficient to keep the mine running for a year. Conditions developed during the last quarter of the year were not encouraging, as the ore was not found on the 2100-ft. level. The ore discovered in the New York Bonanza has been followed a distance of 140 ft., the vein varying from 6 to 20 inches. Some sinking and raising has been done at the intersection of the cross-fissures, but no ore was found in doing this work. The ore taken out runs from $40 to $50 per ton, in addition to which there is some zinc. The heading of the Snake Creek tunnel has now passed beyond the brecciated limestone through which it has been passing in the last 200 ft. and which has caused trouble on account of water and the necessity of timbering. A little water still appears at the floor, but the face and roof are dry. The face is in a distance of 10,700 ft. Shipments made by Park City operators for January totaled 5618 tons, the Daly West leading with 1815 tons, and the Silver King Coalition second, with 1781 tons.

In Tintic district the May Day reports new ore on the 500-ft. level, where driving was done to cut the orebody opened on the 300. The new find has not been developed sufficiently to determine its extent. The Uncle Sam, which is under the same management as the May Day, is shipping ore valued at $1000 per day. A recent 60-ton shipment netted the company $3300. The new railroad spur that the Scranton people built at a cost of $2000 is in use, and this will effect a saving of 40 cents per ton on all ore hauled. The company will increase its shipments from 700 to 1000 tons per month. Two grades are shipped, about 30% of the ore carrying 34% zinc, the remainder being a zinc-lead ore containing 40% each. Tintic district ore-shipments for the past week are 172 cars, Centennial-Eureka leading with 45 cars, and Iron Blossom second with 39.

In Beaver county the South Utah company has found high-grade ore in virgin ground. The vein has been followed for 100 ft. During January the mill treated 22,090 tons of ore which yielded 2091 tons of concentrate averaging 9.88% copper. Production for the month was 386,764 lb. of copper, 140 oz. gold, and 2532 oz. silver. The average of the concentrate was the lowest since October, but the production of copper was slightly higher than in December, the best previous month. Since October the company has produced 1,259,917 lb. of copper. Under the changed mining methods, which involve a system of back-stoping, 250 men do all work in mine and mill, whereas 400 were required by the old method of square-setting. Mining costs are about 90c. per ton, and milling costs about 50c. Concentration is at the rate of 10 and 11 tons to one. The Revenue, 15 miles west of Newhouse, has been developed during the winter by driving two adits, each 120 ft. long. Recent samplings of some portions of this mine showed ore worth $150 per ton. An old mill is on the ground which will be put in operating condition in the spring, and the ore is to be delivered over an aerial tramway.

Rebuilding the surface workings of the Utah Mines Coalition Co., at Alta, which were wrecked in a recent snowslide, will be commenced at once. The compressor and dynamos were unharmed, but all of the rest is a total wreck. The loss is about $10,000. The new buildings will be erected under a large cliff so as to protect them against a repetition of the disaster. With two weeks of favorable weather the mine can be put in such condition that operation can be resumed. The Cardiff people opened sulphide ore in the north drift in which a 2-ft. streak of ore was being followed. The ore is a higher grade than was the streak, and is similar to that found in the south drift from which the shipments of last summer were made. The Rexall's tunnel is in 800 ft., and a drift on a small fissure 40 ft. back from the face is in malachite. The tunnel will give a depth of 700 ft. on veins which are exposed on the surface. The Howell-Johnson Leasing Co. is making a 20-ton test shipment of ore from the old Maxfield mine which it is operating.

A company of Tintic men has been organized to operate the Galena King at Stockton. The incline will be retimbered and the lower levels explored. This mine has some good ore, but the lower levels were flooded by water. The extension of the Honerine drain-tunnel may overcome this difficulty. The Utah mine, of Fish Springs, shipped three cars of ore in February, and a fourth car is being hauled to the railroad. The Utah Smelting Co. is planning to erect small smelters in different camps during the coming summer. Three of the producing coal mines in the vicinity of Salina have been merged as the Southern Utah Fuel Co. Plans are being made to operate a salt refinery in Millard county, eight miles west of Clear Lake. A large spring brings the salt to the surface as brine, and in the hot months of summer the latter evaporates to a point that precipitates the crystals and does away with the necessity of pumping into beds for a special evaporating process. Two railroad projects are being considered which should benefit the mineral industry of the State. One is to build 60 miles southwest from Wellington, on the Denver & Rio Grande, to the coalfields in Emery county; and the other is to extend the Laramie, Hahn's Peak & Pacific from Fox Park, Wyoming, into the asphalt beds of Wasatch county, eastern Utah. This road is already built 55 miles from the Union Pacific at Laramie, and the projected extension is reported to be fully financed by Boston men.

LONDON

Cornish Tin Mining. — Wheal Kitty and South Crofty. — Historical Data Concerning the Gold Mines of the Kolar Districts.—Success of Mysore Mine.

In the midst of much that is depressing in connection with Cornish tin mining, it is pleasant to record the success of the two re-opened mines, Wheal Kitty and South Crofty. I referred a short time ago to the success attending J. H. Collins' work at Wheal Kitty, and I am now able to give an account of the position at South Crofty. This mine is the near neighbor of Dolcoath and Carn Brea & Tincroft. The veins contain much wolfram and arsenic as well as tin. The mine was acquired for the present company in 1906 by the Allen-Meyerstein group in London. The capital is £50,000 in £1 shares, of which the previous owners received 20,000 shares carrying a liability of 5s. per share, and on the formation of the company the promoters procured subscriptions for 20,000 shares at par. A short time afterward the remaining 10,000 shares were sold at £4 each. The total cash funds were, therefore, £65,000. A new shaft has been sunk and much development work has been done; a modern dressing plant has also been provided. The company first made profits in 1909, when 15% was distributed. It is now announced that the dividend is to be the same for 1910. During 1910 the amount of ore raised was 60,916 tons, and the production was as follows: 630 tons tin concentrate, value £56,561; 126 tons wolfram concentrate, value £13,579; and crude arsenic, 736 tons, value £7664. The total receipts, including sundries, were £77,315, or 25s. 6d. per ton, and the costs £62,500. An allowance of £2968 was made for depreciation, £5000 has been placed to reserve, and £7500 has been distributed as dividend. During the year improvements have been made in the arsenic-refining plant, and the defects which gave rise to a lawsuit for damages have been remedied. The new main shaft is completed to the 1350-ft. level and is now being sunk 120 ft. farther. During the year 4697 ft. of development work has been done, and the ore disclosed has averaged a rather higher content than during the last two years. The manager, Josiah Paull, deserves credit for the way he is conducting development operations, and the energy and enthusiasm of Francis Allen, the chairman, should also receive recognition. The ore is of low grade; it is not clean tin ore, as is that at Wheal Kitty, and requires very careful dressing for the separation of wolfram, pyrite, and arsenopyrite.

As a contrast to the success of South Crofty, the continued failure to win success at Botallack must cause Mr. Allen many moments of regret. At the present time efforts are being made to raise fresh capital by means of a drastic reorganization. The mine was re-opened in 1906 by the Allen-Meyerstein group at the same time as the South Crofty. Owing to the lack of records, and of exact information relative to the state of the workings, the results of operations have been disappointing. The capital of the company consists of £100,000 in ordinary shares of £1 each, 72,103 'A' shares of 5s. each, entitling holders to 5% of the tin sales and half the profits, and £4787 in income bonds; while the money advanced on loan by Cornish Consols, a finance company belonging to the Allen-Meyerstein group, is £20,689. For the protection of creditors the company has had to go into the hands of a liquidator, and the directors are making strenuous efforts to continue operations. It is proposed to form a new company with a capital of £100,000. Holders of the 100,000 ordinary £1 shares in the old company will be offered half the number of new £1 shares on which there will be a liability of 5s.; the holders of the 'A' shares will receive one new share of £1 each in place of four 5s. shares; and the holders of income bonds will receive shares equal to the nominal value of their present holdings. To induce shareholders to come forward, special terms for underwriting are being offered to them. In order to satisfy Cornish Consols for the loans above mentioned, £20,000 in shares are to be issued. The mine, unfortunately, has not enjoyed the advantage of continuous management since it was re-opened. At first William Thomas was manager, then W. R. Thomas, and now A. B. Climas; for a time Bainbridge, Seymour & Co. were the consulting engineers; they have been succeeded by Pettit & Poore. Over £70,000 has been spent during the last four years. The surface plant consists of 20 stamps erected and another 20 ready on the spot, together with concentrating machinery. It is to be hoped that shareholders will persevere in their venture.

The sustained success of the gold mines in the Kolar district of Mysore is apt to make people forget that for years the development of the deposits was a failure and that it was by a mere fluke that operations were continued. Another erroneous idea that many people have is that the titled and military gentlemen whose names appear on the list of directors of John Taylor & Sons' Indian gold

Kolar Goldfield, View From Robertsonpet Road.

mining companies are of the guinea-pig type, so well known in London. So far from this being the case, these gentlemen were practically the fathers of the schemes for opening the mines, and have faithfully followed their fortunes, reaping reward from the profits and not from the markets. It is opportune, therefore, to quote some of the history of the Kolar district that appeared in recent issues of the *Daily News* of Bangalore, India. In local circles in India it is claimed that Mysore was the Ophir of David and Solomon, the argument being that the other products mentioned in the Bible, ivory, sandal-wood, apes, and peacocks, are mentioned in the earliest records, whereas other countries, such as Rhodesia, cannot give similar corroborative evidence. The earliest indisputable testimony relating to gold mining in Mysore is found in the 'Arthasastra' of Kantilya, 750 years after Solomon's time and 250 years B. C.; it is here recorded that gold was worked in the districts of Shimoga and Chittadroog. The numerous old mines found by the Geological Survey in the neighborhood of these two towns testify to the importance of the industry in former times. It has also been shown by inscriptions in the Tanjore temples that active gold production took place in the thirteenth, fourteenth, and fifteenth centuries. In recent times activity dates from 1878, when James Hayes and Walter Elliot obtained a license to mine for gold near the village of Oorgaum. Mr. Elliott, who was the active prospector, died shortly after work was started, and his assistants, Lavelle and O'Brien, continued his work. The first-named found gold quartz near Oorgaum and took it to General De La Poer Beresford, at Bangalore, who started a small syndicate among his fellow officers and acquired the rights over 10 square miles. At this time the boom in the Wynaad district, on the Malabar coast, was at its height, and 25 mining companies, with a total capital of five million pounds, had been floated in London. It was hoped that the proximity of Mysore to Wynaad would be a help among promoters. This hope was not borne out, and no assistance came from London just then. Eventually four companies were formed in India. Of these the Madras, Oorgaum, and Balaghat companies were registered in Madras and were under the management of Arbuthnot & Co., and the Kaiser-i-Hind was registered in Bombay. These were small companies

formed for prospecting work. Promising ore was struck in the Oorgaum in May 1880, and a trial crushing produced 100 oz. from 40 tons. Captain Bell McTaggart, then attached to the artillery at Bangalore, resigned his commission, and proceeded to London with the idea of interesting capitalists. This he was successful in doing, and by the middle of 1881, eleven companies were at work, including the Mysore and the Nundydroog, managed by John Taylor & Sons. The years 1881 to 1885 gave disappointing results. In the latter year only three of the companies were actively working, four having closed, and another four awaiting developments. The historic meeting of the Mysore company was held in 1885 for the purpose of winding up. A number of mining engineers had reported adversely and recommended that operations should cease. The only favorable report came from B. D. Plummer, the superintendent of the Nundydroog mine, and, as he had the support of John Taylor, his views were adopted, though only by a small majority. Work was accordingly continued and Mr. Plummer was made manager. From that day onward the Mysore mine went forward and has won celebrity, and other adjacent mines have also become highly profitable.

ELY, NEVADA

Mill Work Retarded by Frozen Ore.—Giroux Equipment and Development.—Railroad, Utah to Ely.

The extremely cold weather recently prevailing has proved a serious hindrance to the milling operations of the Nevada Consolidated by the freezing of its ores in transit from the mines to the concentrating plant at McGill, a distance of 20 miles. The ore, made wet from melting snow and ice, is taken from the open pit by steam-shovels and dumped into cars, after which it usually stands on sidetracks for several hours before being started to the concentrator, and as the temperature has ranged from 10 to 20° F. below zero, the ore is frozen solid in the cars when it arrives at the plant, and has to be removed by dynamite. The company has been fortunate this year in the fact that the weather has been generally favorable for its operations. It has averaged 8000 tons of ore per day, which will soon be increased to 10,000 tons by the starting of the seventh and eighth sections of its concentrator in April. The heavy snow-fall of the past few weeks is a guaranty of an abundance of water for the summer and fall months, which makes possible the operation of the concentrator to its full capacity.

The Giroux Consolidated has completed the equipment of its Giroux shaft, which has reached the depth of 1400 ft. The 600 and 1200-gal. pumps installed on the 1200-ft. level are gradually draining the old workings. Development is progressing on the 770 and 1200-ft. levels, and a cross-cut will be started next week from the 1400-ft. station to the Alpha workings. The company will soon commence shipping high-grade smelting ore to the Tooele smelter in Utah. No announcement has been made as to when the concentration of sulphide ores will be commenced. The company has a concentrating plant of 500 tons capacity which could be put in condition to operate in a short time, but the water-supply now available is not sufficient to keep it in steady operation. The management is hopeful that with the development on the 1400-ft. level a sufficient water supply can be obtained from that source to meet the requirements of the mill.

It seems probable that a railroad will be constructed from Tintic, Utah, to the Ely district. The Tooele smelter, owned by the Cole-Ryan people, is unable to get a sufficient tonnage of ore from the mines of Utah to keep it in profitable operation, hence the owners are anxious to have a direct transportation line into the Ely district. The construction of the road, it is understood, will be backed by W. A. Clark and the Cole-Ryan interests. This road would give the Giroux company, controlled by Cole and Ryan, a direct outlet for its ores and concentrates to the smelter at Tooele, and would also insure it a reasonable freight rate on all supplies coming from the East. It would obviate the necessity of this company building a smelter in Ely district, which might cost as much as the construction and equipment of the proposed road. The length of the proposed road would be about 100 miles, and the line would serve several other mining camps of note between Tintic and the Ely district. The Ely Consolidated is developing large bodies of low-grade sulphide ores on its 500-ft. level. It is the intention of the management to resume sinking the Zack shaft, and make it 600 ft. deep. The Boston-Ely is meeting with success in driving its cross-cut on the 1245-ft. level to the contact.

REPUBLIC, WASHINGTON

New Development Planned.—Plant of the North Washington Power & Reduction Co.—Extension of Lone Pine Vein.

The Eureka-Republic company is to be organized for the purpose of developing and operating the Mountain View, Iron Mask, Flag Hill, and Bodie claims, the deed for which has not yet passed. The Flag Hill has yielded some rich ore from small lateral veins, specimens of which showed native gold. A north-south vein on the same claim has been developed by an adit and cross-cut, showing a width of from 2 to 5 ft., with ore running from $2

Lone Pine Vein, Republic, Washington.

or $3 to $14 per ton, a large tonnage of which, already mined, remains on the dump. The Iron Mask adjoins the Flag Hill on the east and crops 4 to 5 ft. wide for some distance. The only development consists in pits and open-cuts in rather low-grade ore, which will pay a small profit over the costs of mining, haulage, and milling. The Mountain View adjoins the Flag Hill on the southwest and presents good prospects. The Bodie claim is situated in a separate zone, on the southerly extension of the San Poil mine. A 2-compartment shaft was sunk in the hanging wall to a depth of 200 ft., from the bottom of which the vein may be tapped by a short cross-cut.

The construction of the mill for the North Washington Power & Reduction Co. is well advanced, and the management believes it will prove to be a successful metallurgical plant. The method of treating the ores to be adopted involves old and well known principles, but the machinery to be employed, from the coarse crushing of the ore to the recovery of the bullion, will all be of the latest pattern. The concrete retaining walls for the main building are finished. The excavations for the Chilean and

tube-mills and coarse crushers are practically completed. The framing of timbers for each section of the plant is well along. The shed for the precipitation tanks and filter-presses has been built, and the framework for the main section of the mill is up and ready for the sheeting. All of the machinery has been ordered and is in transit. It has been discovered that the Lone Pine vein, in its northeasterly course, not only crosses the Insurgent ground, but passes beyond it into the Last Chance claim, owned by the Lone Pine-Surprise Consolidated M. Co. Charles P. Robbins, of that company, accompanied by Richard Marsh, an assayer, came into camp from Spokane, and examined the premises, with a view to future action, either in the way of developing or leasing and bonding the ground now, for the first time, known to contain a rich vein. The discovery was made at a depth of nearly 200 ft. Where the vein should crop out on the Last Chance ground, the surface débris is deep and is believed to cover the apex from sight.

MEXICO

Mining and Transportation Interrupted in Chihuahua.—Cookson & Co. Buying Lead Bullion.— Contracts for Railroad Building. —Veracruz Oilfields.—Operations at Guanajuato.—The San Toy.

Mining operations in western Chihuahua have been checked perceptibly by the revolutionary disturbances in that State. The concerns that have continued to operate have done so under difficulties, and if the trouble continues, the obtaining of supplies and the safe transportation of bullion and pay-roll money may become such serious questions as to cause a widespread suspension of operations. Due to traffic interruptions on Chihuahua railroads, it has been necessary to make shipments of products through Sonora, and to obtain stores through Sonora points. There has been some revolutionary activity in the State of Sonora, and traffic on the Yaqui River line of the Southern Pacific has been interrupted. The disturbed conditions have resulted in brigandage in various sections, and some mining concerns have suffered. The revolutionary disturbance has lasted longer than was believed probable when the first outbreak occurred, and the situation has steadily grown more serious. There have been a few outbreaks in the southern portion of the Republic, but so far the Government has been able to prevent extensive trouble there. Important changes in the official family of President Diaz are reported to be pending.

The lead bullion of the Towne smelter at San Luis Potosi, which now goes to the United States, may be contracted for by Cookson & Co., the lead and antimony refiners of Newcastle-on-Tyne, England. The matter is now under consideration, and Clive Cookson, one of the principals, will soon arrive in Mexico in connection with that and other business affairs. For several years the Cooksons have purchased the lead output of the Torreon smelter, and they have been notified by the management of that plant that a material increase in production is anticipated this year, beginning in March. This results from the contract recently made with the Compañia Minera de Naica for the output of its lead-silver mines in the Naica camp of Chihuahua. Several hundred tons per day will be supplied to the Torreon plant. The Cooksons own the principal antimony mines in Mexico, situated in the States of San Luis Potosi and Queretaro, and operate an antimony smelter at Wadley, a station on the National railroad in San Luis Potosi. This smelter product amounts to hundreds of tons per month, and is shipped to England through the port of Tampico. The antimony properties were purchased several years ago from M. Elsasser and A. Weill, of Mexico City, each of the men receiving £80,000. The only antimony properties distant from transportation are those at Santa Maria de Mlera, in the State of Queretaro, a wagon-haul of about 100 kilometres to Bernal, on the National road, being necessary. Contracts for the railroad that will open the Sombrerete, Chalchihultes, and Nieves mining districts of Zacatecas, and the Nombre de Dios district of Durango, have been let by the National Railways of Mexico to the Compañia Bancaria de Obras y Bienes Raices, and the International Contracting Co. The former, which has already commenced work, will build 170 kilometres out of the city of Durango, and the latter will build from Cañitas, a station on the Mexican Central in Zacatecas, to Sombrerete, 126 kilometres. The Robert S. Towne interests, having extensive holdings in the Zacatecas districts, that will be opened, and which formerly held the concessions for the railroad, have agreed to a cash contribution to the construction fund, and subsidies aggregating $1,280,000 have been granted by the States of Zacatecas and Durango. The 296 kilometres of railroad will cost several million pesos. The town of Sombrerete will be served by a branch 11 kilometres long, its situation in the mountains making impracticable the construction of the railroad through it. A few years ago the Towne people organized a company to build this railroad, but the financial depression in the United States interfered with the plans, and some time later the concessions were taken over by the National Railways. A railroad that will benefit the Sonora mining industry is under construction by the Mexican Union Railway Co., the English concern that last year took over the mineral railroad extending from Torres, on the Sonora

State of Chihuahua, Mexico.

railway, to Represo. This line is to be extended from Represo to Ures, about 70 kilometres. It is expected to have the first 10 kilometres completed in March.

Recent developments in the oil districts of Veracruz are causing oil men to look to the future, and the formation of a producers' agency, patterned after the organizations that have proved successful in California, is being given consideration. California men interested in Mexican oil are expected to lead in the movement. An abundant supply of fuel-oil will solve Mexico's fuel problem, and benefits will be hastened by an organization that will contract to market the products and guarantee deliveries to consumers. Prices of oil lands and oil leases have advanced as a result of the gushers in the Juan Casiano and Potrero del Llano fields. E. L. Doheny, head of the Mexican Petroleum and Huasteca Petroleum companies, has announced that $2,500,000 will be spent in constructing a pipe-line from the Juan Casiano field to Mexico City. A concession for such a line was granted by the Mexican Government a few days ago, and right-of-way for a portion of the distance has been arranged. The pipe-line will be built as far as some convenient railroad point on the high central table-land. The Juan Casiano field is to be given a railroad to connect with

water transportation. The great gusher brought in by the Pearson interests in the Potrero del Llano field is now under control, and much of the oil is being saved.

Twenty of the 40 stamps of the new mill of the Providencia Mining & Milling Co., in the Guanajuato district, are operating, and the other 20 will be soon in use. It is estimated that the ore reserves in the company's Tajo de Dolores mine represent about five years supply for the mill. The Proprietary Mines Co. of America is financing both the Providencia M. & M. Co. and the Mineral Development Co., and due to the fact that its attention has been concentrated on the Providencia plant, the Nueva Luz work of the Mineral Development has been temporarily suspended. Now it is not expected to reach the mother lode of the Guanajuato district with the Nueva Luz cross-cut before fall. The Oro Grande Mines Co. has increased the capacity of the Guanajuato Amalgamated plant, taken over last year, to 500 tons per day, by adding re-grinding equipment. The Jesus Maria mine, an Amalgamated property, has been shut down, and ore for the plant is being obtained from the Refugio and Bolañitos mines and dumps of the Oro Grande. The company is making a monthly profit from milling, and is spending the most of it in unwatering the mine and development. An aerial tramway, 2 kilometres long, is being built to give the San Matias custom mill, of the Mexican Milling & Transportation Co., connection with dumps and open-cuts beyond the Sirena mine, in the Guanajuato district. A large tonnage of low-grade ore can be obtained. Due to a scarcity of profitable ore, only 40 of the 80 stamps of the Guanajuato Consolidated Co. are now in operation. The annual report of the San Toy Mining Co., operating in the Santa Eulalia district of Chihuahua, show that in 1910 the company marketed 20,181 tons of ore, of a gross value of $529,470. The net income for the year was $437,563, and the net profits $157,566. At the end of the year the undivided profits amounted to $295,350.

NEW YORK

Unchanged Financial Status. — Retirement of Gould from Mo. P. — Decision of Interstate Commerce Commission.—Support for Mining Issues.—The Guggenheim Exploration Co.— Pioche Merger.

Eastern financial affairs have aroused little interest during the past week. Any excuse is made to serve in justification of prevailing dullness. Adopting the habit of the Supreme Court of the handing down its decisions on Monday, the first business of the day of each week is given to watching the wire for any possible action in the important cases pending before that tribunal. The holidays have been made to serve also as excuses for stagnation in the market. The simple truth is that the situation remains unchanged, and for the present the stock market is playing to an empty house. One important event of the week is the apparently complete abdication of George J. Gould as the controlling head of the Missouri Pacific railway. This step marks the passing of the Gould influence in American financial affairs. It is said that Mr. Gould is to retire not only from the presidency of the road mentioned, but from all active business. The possibility of tariff changes, the prospect of an extra session of Congress, the admitted need of currency reform on the one hand and the disposition of the general public to oppose the centralization of financial power on the other, are elements adverse to creating and maintaining market movement. The great transportation companies have been forced to yield to public demand in the recognition of commissions and commerce courts, all tending to force the public service corporations to go upon an investment basis. The important event of the week in market circles was the decision of the Interstate Commerce Commission, denying the increase in freight rates demanded by the railroad companies. The importance of the decision goes to the stock market rather than to any matters of railroading, and is a more radical step in the direction of terminating any speculation in rails than any yet taken. The effect is stagnation during a stage of transition, and speculation must turn to issues having a natural hazard: the monopoly of trading enjoyed by the New York Stock Exchange must either dry up for lack of public support, or it must take steps in a direction in which some advances have already been made. With markets in mining issues properly protected and placed upon a basis where the element of good faith can be assured, public support will be given freely. The natural hazard of mining has no terrors for the investor. He is willing to lose to Mother Nature. There are to be some changes in Eastern financial markets. Investment brokers may become more numerous, and while mining matters could hardly be duller, the logic of events points to a wider and more general activity than has ever been known heretofore. The promised fight by Thomas L. Chadbourne, of Houghton, Michigan, against the proposed Calumet & Hecla consolidation has already drawn the fire of the management of the big company and also a warm retort from J. Parke Channing. The last-named gentleman resents the assertion of Mr. Chadbourne that the valuation placed upon the Ahmeek, in which Mr. Chadbourne is most largely interested, was not as high as the mine deserved. Mr. Channing's reply, in part, is: "In valuing a property, I know neither one side nor the other, and its past record and future prospects alone guide me in my decision." It is certain that in so large a task as the appraisal of the properties of the Lake copper country, it would be a waste of time to proceed upon any other basis. To have a deciding voice in so important a piece of work is about as much glory as an engineer might expect to attain in his career. While the Boston Stock Exchange committee has reported favorably, the rank and file of the brokers are hoping that it may not be consummated. Many of the companies to be included are ranked as semi-speculative, and their stocks are comparatively active. For all these to be merged in one issue, and that of such an investment character as to almost preclude speculation in it, means a heavy loss in commissions for Boston brokers.

The Guggenheim Exploration Co. is to ask the public to come in. The concern has been something of a close corporation, though the stock has been traded in on the Curb. Now the capital stock is to be increased from $20,000,000 to $50,000,000; a 100% stock dividend is to be declared; the remaining ten millions of new capital stock will be held in the treasury, the forty millions which will then be outstanding will be put on a 6% dividend basis, and application will be made for admission to the New York Stock Echange. Whether this is a step in the way of eventually making a merger of all the Guggenheim companies, remains to be seen. The Exploration company has always been looked upon as the most successful of the Guggenheim corporations, having been the receptacle of a large share of the Nevada Consolidated and Utah Copper dividends. The merger of the properties at Pioche, Nevada, which has been prematurely announced two or three times, is now said to be nearing completion. The consolidation, as at present contemplated, will include the Nevada-Utah, the Consolidated Pioche, the Ohio-Kentucky, and the Prince Consolidated. Although the Consolidated Gold Fields of South Africa, Ltd., has failed to acquire the Golden Cycle mine at Cripple Creek, the company evidently intends to broaden its operations in America. A subsidiary company has been formed under the English law, and the services of John Hays Hammond as consulting engineer has been secured. The twelve stockholders of the United Verde Copper Co. held an annual meeting this week in New York. Some time ago W. A. Clark was quoted as saying that "if there is a marked increase in copper production, it must come from the porphyry mines." His position is not altogether supported by the figures on the United Verde production, which show 38,663,880 lb. for 1910, as compared with 36,694,063 in 1909, and 36,183,089 in 1908, while in 1907, the year of high prices, the property turned out but 33,012,339 lb. If the porphyry mines made high records for themselves last year, so did the United Verde.——The consolidation of the Ray Central and the Arizona Hercules is said to be definitely agreed upon. Ray Central has not been making great progress recently; the Weed & Probert report has not yet been given out.

General Mining News

ALASKA

BERNERS BAY REGION

Bulletin 446 of the U. S. Geological Survey, lately issued, deals with the topography and geology of a region of 50 square miles contiguous to Berners Bay, situated 45 miles northwest of Juneau. The bulletin describes the fissure veins, quartz veinlets in diorite, and stringer lodes of that region, and gives data concerning 12 mining properties in that district, consisting of the Ivanhoe, Horrible, Ophir, Bear, Kensington, Eureka, Comet, Johnson, Indiana, Jualin, Fremming, and Greek Boy. There are five mills in the region, having in all 90 stamps. The ores of the district comprise gold, chalcopyrite, galena, sphalerite, in quartz, calcite, dolomite, sericite, epidote, and chlorite. These mines are on Sherman and Johnson creeks.

COPPER RIVER

The Bonanza copper mines are situated in Wrangle mountains, close to a stream called the Kennicott, which flows into the Nizina, the latter emptying into the Chitina, the principal tributary of the Copper river. Kennicott, at the lower camp of the Bonanza, is the terminal station of the Copper River & Northwestern railroad, which starts at Cordova, traverses a 40-mile stretch of tide-flats, proceeds nearly 100 miles northerly along Copper river, thence nearly easterly along the course of the Chitina and Nizina, making a route of 200 miles between Cordova and Kennicott. The Bonanza camp is supplied with bunk and mess houses, warehouses, sawmill, assay office, and other buildings. The lower camp is connected with the mines by a 15,000-ft. aerial tramway, the upper terminal being 4000 ft. higher than the lower terminal. It is stated that a concentrator is being built at the lower camp. The mine is developed by 2000 ft. of workings. The ores consist of azurite on and near the surface, and chalcocite in the deeper workings.

THE INNOKO

Pay-gravel has been found on Ophir and Spruce creeks, where there will be activity next spring. Some winter

Map of Innoko Region.

dumps have accumulated on Little creek, and these will be sluiced when the season opens. Gaines creek is reported to have good pay-gravel, where work is being planned for next spring; this may be said of Yankee creek, also. These are all tributary streams of the Innoko.

PRINCE WILLIAM SOUND

Business men of Valdez have had surveyed, and purpose building, a 7-mile railroad from that place to Mineral creek, which is the centre of mining activity. The Mineral Creek Power Co. has been incorporated, the plan of the company being to generate power for the operation of stamp-mills to be built in that vicinity this year. Joseph Bourke, F. M. Boyle, C. D. Shaw, and M. Blum are the incorporators. The same company intends erecting a stamp-mill to treat custom ores being mined in small lots on Mineral creek. Work is in progress in placer ground of that locality. The Black Diamond lode mine has been opened by an adit whereby a 5-ft. vein of gold ore of milling grade was found. The Valdez-Bonanza, being developed by adit levels, has a 7-ft. vein, the ore in which assays from a trace of gold to $292 per ton. It is claimed that a body of iron ore, suitable as fluxing material, has been discovered on Hinchinbrook island.

THE YUKON

Hydraulic equipment is being hauled from Circle City to the Barnette placers on Mastodon creek. Berry and Lamb are hauling supplies to their placer properties on Eagle and Mammoth creeks, where work is to begin with the opening of the season.

ARIZONA

COCHISE COUNTY

The Copper Queen Copper Co. has a force of 75 men engaged in construction work at its smelting plant at Douglas. Two reverberatory furnaces, and six roasters of the McDougall pattern, are being built. The concrete foundations for the roasters, and for the steel building in which they are to be housed, are complete. Storage-bins, intended to hold the concentrate that is required to be roasted, are of concrete, and these are nearly finished. The concentrate is to be delivered to the bins in cars hauled over an elevated track; it will be conveyed to the roasters by a belt-elevator. The new stack, to be 22 ft. diam., 300 ft. high, supported by a concrete foundation 60 ft. diam., has been commenced, the bricks for which are to be manufactured at Ancho, New Mexico. An extension to the flue-dust chamber, now finished, was built of tiling. The new converter flue, connecting with the recently built dust-chamber, is of sufficient capacity to carry the gas and fume from the 8 stands of converters with which it is connected. This flue is 11 ft. diam. at the end where it receives the gas and fume, and 13 ft. diam. where it discharges them into the dust-chamber. A 276-ft. tunnel, 30 by 15-ft. cross-section, was made to serve for slag-haulage. The tunnel is lined with concrete walls 4 ft. thick, with a supporting wall in the centre. With the completion of the reverberatories and roasters the concentrate, fine ore, and flue-dust will be treated in them instead of in the blast-furnaces.

MOHAVE COUNTY

As the result of a 3-weeks run of the Tom Reed Mines Co.'s 10-stamp mill, in Goldroad district, a clean-up of bullion was made, valued at $60,000. The shaft at this mine is to be sunk to a depth of 500 ft. The power system is to be improved. The Chloride district has a camp called Copperville, in which are the Copperville, Samoan, Lucky Boy, and other veins. The project of cross-cutting all those veins, by driving an adit, probably will be undertaken by the Arizona Southwestern Copper Co. Such an adit would cut the Samoan vein, owned by this company, at 700-ft. depth, which is considered below the leached zone. The Lucky Boy and Brighter Days veins are on claims belonging to T. B. Scott. The mine of the Frisco Mines Co., situated at Union Pass, has been sufficiently developed to expose about 750,000 tons of ore, estimated to have an average value of $12.50 per ton. The *Kingman Miner*, whose editor inspected the property, states that the vein has a dip of 20° and a width of 35 ft. The mill, recently built, has a Gates crusher, a 6-ft. conical Hardinge ball-mill, and a tube-mill, by which the material is reduced to 200-mesh. It is then cyanided in Pachuca agitat-

ing tanks, and Burt filters. The mill machinery is operated by Meitz and Weiss oil-burning engines, said to supply power at a cost of $5.50 less per horse-power month than steam-power. The oil costs about 6c. per gallon delivered at the mill.

YAVAPAI COUNTY

(Special Correspondence.)—G. W. Hull, of Jerome, is to resume development work on the claims of the Huron Gold company, situated near Huron station. The old workings have been cleaned out, and the buildings made ready for occupancy. The Eleanor Placer M. Co. is to commence work on properties in French gulch, near Prescott. Results of tests made are favorable, and the owners expect a profitable season.

Prescott, February 24.

The United Gold Mines Co., operating a mine and a small Nissen stamp-mill at Congress, has opened the property by sinking a 540-ft. shaft, from a number of stations in which the ore is developed. A larger mill is required and steps have been taken to raise funds to buy additional equipment. The directors are D. J. Sullivan, T. M. McGill, C. M. Raible, D. A. Burke, H. M. Sullivan, H. A. Cronin, and S. Newhall.

YUMA COUNTY

George Wood and A. J. Pickerell have sold to F. L. Smith, of Detroit, the Mineral Hill mines, situated 18 miles east of Parker. The property comprises 13 claims, and lies within two miles of the Planet mine, in the Bill Williams country. It has been developed by 500 ft. adits, drifts, and cross-cuts, whereby bodies of copper-iron ore are exposed.

CALIFORNIA

AMADOR COUNTY

The 40-stamp mill at the Zelia mine is operating again after a brief shut-down. The Bunker Hill mill, whose batteries were recently increased from 20 to 40 stamps, is operating at full capacity, and it is claimed there is sufficient ore accessible in the mine to keep the mill operating several years. Dividend No. 56, of 5c. per share, was paid on February 15.

ELDORADO COUNTY

A. G. Kulberg and Charles Edner have built a stamp-mill in the vicinity of Fairplay. It is to be operated on ore taken from a 4-ft. vein on their property.

INYO COUNTY

Ballarat is situated in Panamint valley, between the Argus range on the west and the Panamint range on the east, and that region is called the South Park mining district, which is said to have good surface indications of mineralization. Ballarat has a publicity committee which is trying to establish a mineral collection of ores representative of that district. The town is about 45 miles east of the Owens valley line of the Southern Pacific Co., and is 70 to 80 miles west of the Tonopah & Tidewater road.

KERN COUNTY

The Yellow Aster mine, Randsburg, has a force of 150 to 200 miners and millmen. There are 130 stamps operating in the mill. Much of the ore is exposed by stripping off the overburden, and is subsequently mined on the glory-hole plan. Three 7-ton locomotives and 21 3-ton cars were added to equipment in 1910. These are employed in removing waste, and in hauling ore to the mill. Ore said to assay $50 to $100 per ton has been found on the 425-ft. level of the Sunshine mine, owned by T. W. and B. M. Atkinson. Ore of high grade has accumulated on the 200, 300, and 425-ft. levels; on this the mill is to be operated. Development and stoping are being done with three air-drills. C. P. Christensen is superintendent for the Stanford Mining & Reduction Co., which operates a 10-stamp mill at Johannesburg. The mill has been running on ore taken from the Pinmore mine.

MARIPOSA COUNTY

The interests of J. E. Myers and associates in the Bullion Hill M. Co. have been purchased by J. M. and A. L. Richardson of Minneapolis. The company owns the Bullion Hill mine at Exchequer. The office of the company has been moved to Merced. Development work is to proceed under direction of B. R. Binns. The building of a milling plant is one of the probabilities.

MONO COUNTY

The Tri-Metal M. Co., which erected a cyanide plant at Benton to treat a dump of 20,000 tons of tailing, is leaching at the rate of 70 tons per day.

NEVADA COUNTY

The Murchie mining property near Nevada City has been purchased at trustee's sale by John J. Myers and C. F. Humphrey at $91,000. The buyers expect to organize a company to which the property will be transferred, and the intention is to begin operations later in the season. The prospect is that drift mining may be resumed this season at North Bloomfield, on what is known as the Humbug Bar Townsite mine, in which lot owners are interested. North Bloomfield is situated on a high bar between two forks of Humbug creek, and the townsite is said to be underlain by auriferous gravel. C. J. Graham has a bond and lease for most of the gravel rights of the place. The Red Cross mine, at Omega, was sold by the county to satisfy a claim for taxes. It was bid in by W. H. Martin at $2600, in the interest of E. J. Deane, who previously had a bond on it. Mr. Deane has a company organized to take over the property and operate it. The equipment consists of a 20-stamp mill, a sawmill, and other buildings.

SAN BERNARDINO COUNTY

The U. S. Smelting, Refining & Mining Co., which finds its lead concentrator and Huff electrostatic separators, for iron-zinc ores, a success at Midvale, Utah, may install separators of the Huff pattern in its concentrating plant at Needles. Mr. Mougin, who has charge of the Midvale plant, is at Needles making tests on ores received at that place. The California Gold & Copper Co. has built a leaching plant near Vontrigger, where it has developed a body of ore on the 200-ft. level of the mine.

SHASTA COUNTY

The Mammoth Copper Co. now has three furnaces in blast in its Kennett plant, and it is claimed the bag-house is disposing of the fume in a satisfactory manner; but it is probable that the bag-house will be increased in capacity.

SIERRA COUNTY

Mining auriferous gravel in this county has received an impetus by the success of operations of the Gold Star and Monte Cristo, at Fir Cap ridge, the Deadwood Con. at Poker Flat, the Gibraltar, near Hawley ranch, and the Columbia, on American hill. It is claimed there are extensive channels of gold-bearing gravel in Sierra county which never have been worked, some of which lie beneath a lava capping. The Gold Star gravel mine, at Forest, lately produced 300 mine-cars of gravel in 30 days, from which gold valued at $6.70 per car was extracted. The property belongs to the Alleghany Channel & Gold Quartz M. Co. The channel has been opened by bedrock adit-levels, and is said to have a width of 250 ft., and has been further developed by drifts and raises. The Alaska mine, situated near Pike City, has a vein that is 8 ft. wide at the face of the drift on the 400-ft. level. The ore extracted from this level contains $4 per ton in gold. The workings are kept free of water by operating electric pumps.

COLORADO

BOULDER COUNTY

The Zophar M. Co., developing a tungsten property in Nederland district, has installed an air-compressor, and purchased drills, to drive an adit into Baker hill, whereby a depth of 500 ft. on the orebody is to be attained. Weaver Bros. are erecting a small cyanide plant at Salina. The Metal Mining Association is considering the project of erecting a cyanide plant of large capacity to treat custom ores of this county.

CLEAR CREEK COUNTY

(Special Correspondence.)—Driving has been started on the Ocean Wave vein that was intersected 5300 ft. from the portal of the Capital adit. An 8-in. streak of ore is being followed. John Hurley is operating under lease. N. Williams, of the Ruler property, has uncovered a 6-in. streak of ore assaying $65 per ton in gold, silver, and copper. J. Hansen has the contract to drive the west drift on the Commonwealth vein, intersected 5000 ft. from the portal of the Wilcox adit. Machine drills have been brought into use. A body of zinc ore 2 ft. wide has been found in the east drift on the Mendota vein, opened by the Victoria adit, by the Mendota Mines Co., lessee. A carload of ore was shipped last week from the Scepter mine, on Democrat mountain, to the Stahler concentrating plant in Denver, where tests are being made.

Georgetown, February 19.

(Special Correspondence.)—The Colorado Blue Bell M. Co. is installing an electric-driven air-compressor and hoist, and machine drills. B. Martelon is manager. It is stated that work will be resumed next month in the McClelland adit, the portal of which is at Dumont. The bore is 7000 ft. long, but it will be necessary to drive on the Freeland vein 1000 ft. before the heading will cut under the old shaft. A 1200-ft. raise will then be made to drain the mine workings. An 8-in. streak of ore, assaying $30 per ton, has been opened at the breast of the Hoosac adit. Driving has been started to explore contiguous ground. The Metropolitan adit, on Donaldson mountain, is being driven at the rate of 7 ft. per day. The working force at the Oneida, at Freeland, is being increased, and ore shipments amount to 30 tons per day. The ore is entirely of a smelting grade and brings from $50 to $55 per ton. A force of 40 men is employed at the Saratoga mine, on Seaton mountain. Ore is being shipped to the Golden smelter for treatment. John Owen is manager. Machol & Co., lessees on the Seaton mine, and operating through the Newhouse adit, are breaking 25 tons of mill-dirt per day. The ore is sent to the Newton mill for concentration.

Idaho Springs, February 19.

LAKE COUNTY

The Progressive shaft, on the north Fryer hill, is being put in good condition, and a station is being cut out for the installation of a pump. The old hoisting plant is being replaced by a new one. Prospecting is in progress on the first level in an effort to open a shoot of ore. J. Johnson and partners, lessees on the McRea, Fryer hill, after prospecting and developing eight months, have opened a 5-ft. vein of silver ore. By continuing to drive on this vein the operators think lead ore may be found, as the occurrence of silver without lead is not usual on Fryer hill. The shipment of a car of ore is to be made. Ore-shipments from the Silent Friend, South Evans gulch, amounts to 500 tons per month; the ore is silicious and contains gold. The property is developed to considerable depth, and is drained by the Yak tunnel. Work on the St. Louis, South Evans gulch, is confined mostly to a streak of ore above the adit level. There is a shaft on the property which has a depth of 300 ft. below the adit, and this is to be sunk 150 ft. deeper, by which it is expected to reach the granite, and it is in this formation that fissures may be found. By this deeper exploration the Kezar M. Co., which owns the property, hopes to open the extension of the Hahnewald oreshoot. J. B. Stewart is in charge of the work. Lessees of the Garbutt mine, Breece hill, after getting the consent of the Ibex M. Co., drove a cross-cut from shaft No. 4 of the Little Johnny group to a position 200 ft. below the bottom of the Garbutt shaft; and they are now raising from that place to make a connection with the shaft. They chose this method in preference to sinking 200 ft. Raney & Newman, lessees on the Matchless, Fryer hill, are shipping 30 to 40 tons of iron ore per day. This ore contains considerable silica.

Bull Hill, Cripple Creek District.

PARK COUNTY

The Moose Smelting & Refining Co., for which J. L. Seward is chief engineer, is to erect a smelting plant at Alma, especially to smelt the ore of the Moose mine, which was operated profitably about 35 years ago. It is claimed the tonnage of ore on the Moose dumps is sufficient to justify the building of the smelter, which is to have a 150-ton furnace. The company is made up of New York men, and has an office at Denver.

SAN JUAN COUNTY

The Silver Ledge mine, situated between Silverton and Red Mountain, has been under development during the winter, and the plan is to have enough ore blocked out by May 1 to warrant starting the mill at that time. The orebody has been opened on the 300 and 500-ft. levels, where it has a width of 30 ft. in some parts. The ore consists of lead-zinc sulphide, accompanied by gold and silver. The mill was operated last season, the product being two kinds of concentrate: one containing 45% zinc

and 8 oz. silver, and another running 79% lead and 9 oz. silver. It is probable that the shaft will be sunk to the depth of 1000 ft. The Iowa and Silver Lake tramways were damaged last week by snowslides, and this caused cessation in transporting ore to the mills for a short time. Much ore is being exposed in the Iowa. The Sunnyside mill, at Eureka, is operating at full capacity; recent experiments with a Richards classifier were satisfactory. The Intersection Leasing Co. is mining and milling ore steadily; the capacity of the mill may be doubled. The Highland Mary mine, on Cunningham gulch, may resume work under new ownership next spring, as negotiations for the purchase of the property are said to be pending.

SAN MIGUEL COUNTY

The Primo Chemical Co. is preparing to start its mill again, at Newmire, for treating vanadium ore, after having been idle since last October. The plant of the Vanadium Alloys Co., situated at the same place, is reported to have resumed operating. The General Vanadium Co., operating at Fall creek, employs 12 miners, and turns out 60 tons per month of ore containing 2½ to 3½% vanadium. The mine is opened by three adits. This company has contracted to purchase similar ore from other producers in this vicinity.

SUMMIT COUNTY

Near Frisco is the King Solomon tunnel, now in nearly 5000 ft., intersecting a number of veins, one of the strongest being vein No. 11. By sinking a winze on this vein a body of ore was found, samples of which assayed 50% lead, and 1½ oz. gold per ton, together with some silver and copper. The force has been increased and work on No. 11 will be aggressive.

TELLER COUNTY (CRIPPLE CREEK)

The cross-cut being driven from the Roosevelt tunnel to the C. K. & N. vein will redound to the benefit of the El Paso mine and other properties of Cripple Creek district. This cross-cut is to be completed within the next few weeks. It is expected to drain the El Paso's lower levels. It is estimated that the tapping of the C. K. & N. watercourse will increase the outflow through the tunnel to 20,000 gal. per minute. The February output of the Blue Bird mine, on Bull hill, was close to 1500 tons of ore. Several lots of 6 and 8-oz. gold ore have been sent out from Dante No. 2 shaft, the ground reached by it being in the hands of lessees. The Cariolanus mine, on Battle mountain, part of which is operated by Erickson Bros. under a sub-lease, has a body of ore of smelting grade on the 500-ft. level. This ore is north of the main shaft. The vein has a width of 2 to 3 ft., and the ore samples 1 to 3 oz. gold per ton. Nelson & Son, also lessees on this property, are mining ore that runs about 1 oz. gold per ton. The Mary McKinney company, operating the mine of that name at Anaconda, has 20 miners employed, producing 50 tons per week incidental to the development being carried on. The main orebodies are still being mined by lessees. Edwin Gaylord has a lease on the Abe Lincoln, situated on Poverty gulch. This property belongs to the Stratton estate. The Golden Cycle has reached a depth of 1600 ft., and this is said to be the deepest shaft in Cripple Creek district.

IDAHO

METAL OUTPUT FOR 1910

F. Cushing Moore, State Inspector of Mines during 1909 and 1910, in his report for the latter year, gives figures showing the production of gold, silver, lead, copper, and zinc of the State by counties. Shoshone county, in which the Coeur d'Alene mining district is situated, stands at the head, as a matter of course, and is credited with 3110 oz. gold, 7,262,271 oz. silver, 229,950,506 lb. lead, 5,003,639 lb. copper, 5,995,600 lb. zinc, of a total value of $15,272,024. Owyhee county ranks second, with a total output of gold and silver valued at $556,925, produced mostly at De Lamar and Silver City; Lemhi is third, with an output of lead, silver, and gold valued at $544,708; Elmore, in which are the mines at Pine, Rocky Bar, and Atlanta, produced gold and silver valued at $214,716; Boise county yielded $180,459, mostly gold from Boise Basin and contiguous country; Custer is credited with a gold, silver, and copper output valued at $178,614, of which $107,586 was for copper; Nez Perce's output of gold and silver was valued at $51,462; Blaine, $38,728; Idaho, $25,945. Each of 11 other counties produced metal in small amounts. The metal production of the State is shown by the following figures: Gold, 49,289 oz.; silver, 7,890,388 oz.; lead, 239,144,570 lb.; copper, 5,837,639 lb.; zinc, 5,995,600 lb. Total valuation of all metals, $17,135,695, as against $15,606,826 for 1909.

SHOSHONE COUNTY

(Special Correspondence.)—The Hecla M. Co., operating the Hecla mine and mill at Burke, paid a dividend of $10,000 on Feb. 20, making a total of $2,140,000 to date. Recent development on the 1200-ft. level resulted in opening strong orebodies. Rich ore has been found on the property of the Pittsburg Lead Co., on Nine Mile, near Wallace. This ore is found in a winze sunk from one of the levels, the vein in which it occurs being 20 ft. wide.

Wallace, February 25.

(Special Correspondence.)—The Jack Waite mine, a new lead producer, situated on one of the tributaries of Eagle creek, 12 miles from Murray, was bonded to the Jack Waite M. Co. on Nov. 1, 1909, the price specified having been $250,000. The final payment of $100,000 was recently made by Lee Mantle, of Butte, one of the principal stockholders, and the title has passed to the purchasing company. In the last 15 months $50,000 has been expended in development and equipment. The lowest adit level, in a distance of 950 ft., gives a vertical depth of 450 ft. on the vein. The principal vein has a width of 6 to 8 ft., is on the contact of quartzite and slate, and contains high-grade steel galena ore.

Murray, February 24.

(Special Correspondence.)—Recent development in the Stewart mine has resulted in opening a vein of lead-silver ore parallel to what has been considered the principal vein. In driving 75 ft. the new vein was proved to be 7 ft. wide, containing ore of milling grade. It has been demonstrated that the Stewart now has three defined veins of ore. Ore-shipments to a concentrating mill at Wallace amount to 350 tons per day.

Kellogg, February 25.

(Special Correspondence.)—Federal Mining & Smelting Co. is making additions to its milling plant at the Morning mine. The building is being enlarged to accommodate a plant for the re-treatment of the middling and slime by means of the MacQuisten tubes. The sorting plant also is being enlarged. It is believed by the company that the new process may go far toward solving the problem of the economical treatment of the Morning ores, which contain carbonate of iron and are low grade. More than 400 men are employed at the mine. The mine of the Gold Hunter M. & S. Co., which has been operated 20 years, and paid but two dividends, now has reserves of ore sufficient to keep the 200-ton mill operating five years. Mine work is now carried on through No. 6 adit-level, having a length of 4700 ft. A winze was sunk to a depth of 200 ft. on this level, 4500 ft. from the portal, and as the result of driving from the base of this winze a shoot of rich ore was opened on the south vein; similar ore was found on the north vein at this depth. It is ascertained that the two veins are dipping toward each other. A new orebody has been opened on the level 400 ft. above No. 6, which is 22 ft. wide. The property is at Mullan, and Dennis Ryan is manager. It is announced that the capacity of the mill is to be doubled.

Mullan, February 25.

MONTANA

DEER LODGE COUNTY

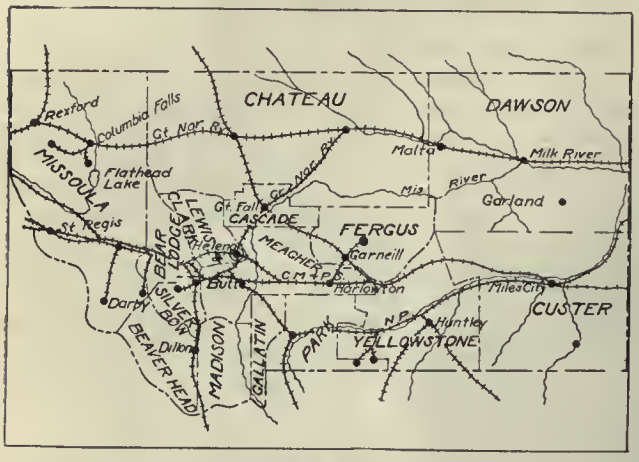
(Special Correspondence.)—The Gold Coin, in the Georgetown district, is likely to pass into the hands of Denver and Eastern investors. A short time ago an option was given to Fred L. Klein of Denver, and later the mine was

examined by H. S. Sanderson of that place, who has returned to Denver with the samples. The Gold Coin is owned by the Anaconda National Bank, controlled by Yegen brothers, and while here Mr. Sanderson was under the special guidance of a representative of the banking firm.

Anaconda, February 25.

FEROUS COUNTY

(Special Correspondence.)—The Rhein Gold Mining Co. has acquired the property of the Meredith Mining Co., better known as the New Year group, situated in Judith basin. It is a gold property, consists of seven claims, and has a good mill. A. S. Wright, of Chicago, is in charge for the new owners, and announces that operations are to be commenced on an extensive scale. The Chicago people obtained the property after it had been placed in the hands of a receiver in consequence of some differences between tne previous owners over the management of affairs. The Barnes-King Gold Mining Co. is to hold its annual meeting



Northern Montana.

at Kendall, March 1. Those who have been in correspondence with some of the New York stockholders say the company may make an effort to purchase the North Moccasin mine, which is to be sold to satisfy a judgment for $100,000. The North Moccasin is known to have a rich gold vein, but a cave-in completely closed the shaft a few years ago, and the owners were unable to raise the money necessary to re-open the mine. Kendall Mining Co., of Kendall, paid its seventy-fifth dividend on Feb. 23, which was $10,000, making a total of $1,355,000 to date. The Kendall mine is controlled by Finch & Campbell of Spokane and their associates. This property, the Cumberland at Maiden, and the Gold Reef at Gilt Edge, have been lately the principal producers of Judith basin.

Lewistown, February 24.

LINCOLN COUNTY

It is asserted that six mining properties in the Libby district are to be in operation this year. One of these is the Hazel T., on which a vein containing 40 in. of steel galena was opened by 70 ft. of driving. Further development showed an increase in width to 10 ft., in which the ore assayed $43 per ton. The same vein, when intersected at another place, proved to be 38 ft. wide. The vein is between porphyry and quartzite. George Chandler of Spokane is one of those interested.

MADISON COUNTY

(Special Correspondence.)—The Bismark mine, situated near the head of South Boulder canyon, is owned by the Montana-Illinois Copper Mining Co. An effort to find the downward extension of a body of copper ore, discovered near the top of the mountain, was recently successful. Under direction of W. L. Credon an old cross-cut in the lower tunnel was extended southerly, which resulted in opening a body of ore which assayed about 2% copper, 2 oz. silver, and $3 in gold. Farther on a body of lead ore, 1 ft. wide, containing 20 to 30% lead, 7 oz. silver, and 1.47% copper was exposed. Further driving opened a third body of ore which assayed 4% copper, 8 oz. silver, and $1.20 in gold per ton. Plans for the first unit of a concentrator are being considered, and as the property has a water-power site, with a railroad close by, the cost of mining and milling would not be high.

Virginia City, February 25.

NEVADA

CLARK COUNTY

F. B. Miller, George Colton, and A. Morrison have taken a lease on a part of the Duplex group at Searchlight. The Quartette Mining Co. recently cyanided 150 tons of mill tailing for Charles Hamil. This stuff resulted from the milling of some ore sent to Searchlight from the Jumbo mine at Hart, Cal., and the treatment was in the nature of a test. James Montgomery and Clarence Summers are mining in Newberry district, 18 miles southeast of Searchlight. They have accumulated some ore that assays $15 per ton. Their camp has a good supply of water.

HUMBOLDT COUNTY

The lessees of the Seven Troughs district are active in development and ore-production. The Tyler Leasing Co., whose shaft on Coalition ground is 425 ft. deep, is to sink 75 ft. deeper. The vein has been opened on the 400-ft. level. The Florence, Fresno, and Kahler & Andregg leases are in active hands. Three other leases have been let on Coalition claims. The Darby Gold Reduction Co., now operating the Mazuma Hills mine, has made the necessary improvements and has let a contract for 500 ft. of sinking. It is estimated that 250 miners are employed in this district.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co., for last week, had an output of 8588 oz. silver and gold, and 45 sacks of concentrate, from 695 tons of ore. The new mill at the Deadwood mines is operating steadily; the first clean-up gave 1600 oz. of gold and silver bullion, and 50 sacks of concentrate. The mill machinery is driven by a De La Vergne high-compression oil engine, the cost of power being estimated at approximately $100 per horsepower per annum. The half-month clean-up at the Socorro mines amounted to 20,000 oz. of silver and gold bullion. The Wilfley tables are to be placed in use again as a means of increasing the mill's capacity. The Gold Dust Mines Co. is drifting east and west on the vein from the point of intersection. Sinking below this level is in progress. The Enterprise M. Co. is sacking high-grade ore taken from the third level, and a winze is being sunk from the fifth level. The Oaks company has development work in progress on several claims of the Tunnel group. The contractors are delivering ore from the mine of the Treasure M. & R. Co. to the mill, and the intention is to increase the tonnage. The unusually heavy fall of snow in the mountains of this region gives assurance of a plentiful water-supply next summer.

Mogollon, February 25.

OREGON

The Oregon legislature has enacted into law the Bureau of Mines bill, providing for the establishment by the State of a mining bureau, to be under direction of the board of regents of the State Agricultural College, at Corvallis. The object sought to be attained is to promote the classification and study of the ores and minerals. An appropriation of $2000 was made, this sum to be used in getting the work started. Oregon mining men are asked to meet in Portland on May 16, 17, and 18 to form a State chapter of the American Mining Congress.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The January production of the Rio Plata Mining Co. amounted to 71,289 oz. silver. The decrease from that of last fall is due to the shortage of labor, caused by the insurrection in Mexico, Chihuahua being the State in which the insurrectos are active.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

DUTY OF MINE OWNER IN CASE OF NEGLECT OF MINE FOREMAN

Where the owner of a mine knows that the mine foreman is neglecting the performance of his duties, or that the mine is in a condition which endangers the health or the safety of the miners, it is his duty to act promptly and have such dangers removed; but where the owner himself is not in fault he can not be made liable for the neglect of duty imposed by the statute upon the mine foreman. He necessarily must operate his mine through others, and when he complies with all statutory provisions enacted for the protection of his workmen by employing competent assistance, he has done all that is required of him and can not be subjected to liability for which he is not responsible.

Dempsey *v.* Buck Run Coal Co., (Penn.) 76 Atlantic 745. March 1910.

LIABILITY OF MINE OWNER FOR INJURY FROM IMPROPER VENTILATION

The statute of Pennsylvania requires the owner of a mine to place the mine and the underground works in charge and daily supervision of a mine foreman. The statute commits to such foreman the charge of matters pertaining to the ventilation of the mine and prohibits the superintendent from interfering with him in the performance of these duties. Accordingly, where the owner of the mine placed a competent mine foreman in charge of the mine, whose duties require him, among other things, to protect the miners against insufficient or inadequate ventilation, such mine owner has complied with the statute requiring him to use precaution for the safety of the miners, and the mine owner is not liable for injury to a miner resulting from neglect or failure of such foreman to properly conduct the air currents along the face of the working places of the mine. In an action to recover damages for injuries to a miner sustained by an explosion of gases in an anthracite coal mine on an alleged failure of the mine owner, a corporation, to perform its duties, it was conceded that the company had employed a competent certified foreman and that at the time of the accident he was in charge of the underground workings of the mine. There was no evidence, however, that the owner had not provided and maintained an adequate supply of pure air for the mine. Neither did the evidence show that the owner had, in any manner, failed to perform the statutory duties imposed on him, unless he should have driven the top-heading in order to permit the air currents to circulate in the breast above the place where the miner was injured. The evidence, according to the decision of the court, showed no failure on the part of the owner to furnish any material required by law, the want of which contributed to the accident. By command of the statute the interior of the mine is taken out of the possession and control of the owner, and placed in charge of a certified foreman, with whom the owner's superintendent is forbidden to interfere, and who has power to compel compliance with his directions so far as they relate to the safety of the miners engaged in the mine. It was therefore the duty of the mine foreman to provide such headings as were necessary to ventilate the mine, and it was his duty, and not the owner's, to determine the necessity for another heading in the breast, and to provide such heading, if good ventilation in that part of the mine required it. Anything and everything that affects the health and safety of the workmen while engaged at their work is, by the statute, placed in the keeping and charge of the mine foreman. Whether the air currents should have been conducted to one breast by means of brattices, or a top-heading should have been driven to another breast, or a heading driven to any other place in the mine for the purpose of ventilating the breast where the accident occurred, were questions to be determined and matters to be regulated by the mine foreman.

Dempsey *v.* Buck Run Coal Co., (Penn.) 76 Atlantic 745. March 1910.

Company Reports

TRINITY GOLD MINING & REDUCTION CO.

This company operates the Headlight, a gold mine near Carrville, Trinity county, California. The first annual report for the year ended November 30, 1910, shows that $25,686 has been spent in the development of ore, of which 400,000 tons have been blocked out, of an estimated net value of $1,200,000. On improvement account, 158,449 has been expended for the improvement of a 40-stamp mill, hydro-electric power plant, electric lighting and water systems, 200-ton cyanide plant, etc., and $14,968 on equipment. Operation began on December 3 and it was expected that by February 1, 1911, it would reach full scale. The ore is to be mined through glory-holes, at a present cost of 52c. per ton, which it is hoped to reduce to 32 cents.

RIO PLATA MINING CO.

This is an American company operating a silver mine in the State of Chihuahua, Mexico. The annual report for the year ended November 30, 1910, shows that 617 tons of ore of an average content of 9.07 oz. silver per ton was shipped to the smelter, and 13,952 tons of ore of an average content of 46.48 oz. silver per ton was milled, one-third of the silver content being recovered by concentration and 86% of the remainder by cyanidation. The cost of mining was $2.45 per ton, cost of milling and concentration $2.05, and the cost of cyaniding $3.90, making a total cost for mining and reduction of $8.40 per ton, or 18c. per ounce of silver recovered. The company made a profit of $245,062 on its operations during the year and has an earned surplus. There remain in the treasury 26,336 shares of capital stock. The improvement account amounts to $351,764, but there is no apparent annual charge for depreciation or for interest on capital. There is also no statement of ore reserves, beyond the mention of 2500 tons of broken ore in the stopes.

PORTLAND GOLD MINING CO.

The annual report of the Portland Gold Mining Co., recently issued, shows that during 1910 the receipts from its mine and mill were $2,122,319. Dividends were paid amounting to $240,000, leaving a cash balance on hand of $134,849. The value of the mine and old and new mills is placed at $4,725,400, which, with the addition of supplies and ore on hand, cash in bank, securities, permanent equipment, and railroad rolling stock, makes a total valuation of $5,402,898. The production of the mine for 1910 was 67,515 tons, of a gross value of $1,241,168. A new mill at the mine was completed during the year, making available for profitable treatment three million tons of ore now on the dump, in addition to large bodies of low-grade ore in the mine. The beneficial effect of the new drainage adit is already becoming evident, as the water in the fifteenth level has receded 17 ft. and is going down at a rate which, if maintained, will drain this level by the end of the summer. The development of new ore has more than kept pace with extraction. Heavy expense was made necessary in 1910 through the removal of the backs of old stopes.

L. VOGELSTEIN & Co. report the following figures of consumption of copper in Germany during 1910:

		Tons.
Imports		184,877
Production		24,000
		208,877
Exports	9,157	
Stock in Hamburg	9,050	
		18,207
Consumption		190,670

The consumption in 1909 was 150,245 tons. Of the imports in 1910, 159,346 tons were from the United States.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. B. McGinnis has gone to Brazil.

F. Lynwood Garrison is at Quebec.

J. W. Hill has been in San Francisco.

C. H. Munro has returned from London.

E. A. Montgomery was in San Francisco.

Charles Janin has returned from Grass Valley.

F. H. Probert is examining the Butte & Superior mine.

Edmund Juessen has returned from Oregon and gone to Blair, Nevada.

S. S. Fowler was in San Francisco on his way from New York to British Columbia.

John L. Whitney is manager at the Water Lily mine near Jamestown, California.

Frank Bailey has gone to London, but will return to British Columbia in a few weeks.

F. H. Morley and wife sailed on Tuesday on the *Manchuria* for a three weeks holiday in Hawaii.

Fred L. Morris returned to San Francisco from New Zealand on the steamer *Oarangi*, arriving March 4.

Baylies C. Clark has been appointed superintendent for the Lightner Gold Mining Co. at Angels Camp, California.

H. G. McMillan has succeeded Ernest Bamberger as manager for the Daly West M. Co., operating at Park City, Utah.

H. W. Ross is in San Francisco. He will leave soon for Casapalca, Peru, where he will be manager for Backus & Johnston.

C. F. Tolman, of the University of Arizona, delivered a lecture on 'Arizona Mines and Mining,' at Prescott, on February 23.

Henry M. Adkinson, manager for the Gold Pioneer M. Co., who has been in Telluride district two years, is soon to be in Denver.

L. A. Greene, business manager of the *Mining and Scientific Press*, was married February 27 to Miss Mollie Mathes of Oakland, California.

The American Society of Mechanical Engineers will hold its sixty-third meeting at Pittsburg, Pennsylvania, May 30 to June 2, inclusive.

A Congress of Technology will be held in Boston on April 10 and 11, in celebration of the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology. Fifty or more papers will be presented at the Congress, written by graduates of the Institute, and will thus serve to record the part the alumni of the institution have taken in the development of scientific industry.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the Mining and Scientific Press.

Syllabus of a Course of Lectures on Economic Geology. By John C. Branner. Third edition. Pp. 503. Ill., index. Stanford University, 1911.

This work is intended primarily for the use of students both while in college and afterward. It is printed on one side of each leaf only, so that the opposite page may be used to enter notes from lectures. It is a most valuable treatise to the student of geology and mining. It is replete with references, which are of much value in pursuit of the subject.

The following publications have been recently issued by the U. S. Geological Survey:

Mineral Resources, 1909: 'The Production of Petroleum in 1909,' by D. T. Day; 1910; 129 pp. 'Lithium in 1909,' by F. L. Hess; 1910; 7 pp. 'The Production of Tungsten, Nickel, Cobalt, Vanadium, Titanium, Molybdenum, Tantalum, Uranium, and Tin in 1909,' by F. L. Hess; 1910; 16 pp. 'The Production of Anthracite Coal in 1909,' by Edward W. Parker; 1911; 12 pp. 'The Production of Quicksilver in 1909,' by H. D. McCaskey; 1911; 13 pp. 'The Production of Mica in 1909,' by Douglas B. Sterrett; 1911; 14 pp. 'The Production of Antimony, Arsenic, Bismuth, and Selenium in 1909,' by Frank L. Hess; 1911; 9 pp. 'Gold, Silver, Copper, Lead, and Zinc in the Eastern States in 1909' (mine production), by H. D. McCaskey; 1911; 17 pp. 'The Production of Slate in 1909,' by A. T. Coons; 1911; 14 pp. 'The Production of Tungsten, Nickel, Cobalt, Vanadium, Titanium, Molybdenum, Uranium, Tantalum, and Tin in 1909,' by F. L. Hess; 1911; 16 pp.

'Thirty-first Annual Report of the Director of the United States Geological Survey to the Secretary of the Interior. 1910.' 131 pp.; 2 pl.

Bulletins: No. 436. 'Fauna of the phosphate beds of the Park City formation in Idaho, Utah, and Wyoming,' by G. H. Girty. 1910. 82 pp.; 7 pl. No. 441. 'Results of spirit-leveling in Alabama, Georgia, North Carolina, South Carolina, and Tennessee, 1896 to 1909, inclusive; R. B. Marshall, chief geographer. 1910.' 145 pp. No. 443. 'Reconnaissance of the geology and mineral resources of Prince William Sound, Alaska,' by U. S. Grant and D. F. Higgins. 1910. 89 pp.; 12 pl.

Water-Supply Paper: No. 262. 'Surface water-supply of the United States, 1909, Part II, South Atlantic Coast and eastern Gulf of Mexico,' prepared by M. R. Hall and R. H. Bolster. 1910. 150 pp.; 5 pl.

Geologic Folio: No. 174. 'Johnstown (Pa.) Folio,' by W. C. Phalen; 1910; 15 folio pages of text, 3 maps, 1 columnar section; price 25c. To be published also in octavo form, price 50c.

The Geological Survey has copies of these publications for free distribution (except the one whose price is stated), but can not give more than one copy to any one person, and requests for all the papers can not be granted unless satisfactory reason is given. Applications should be addressed to The Director, U. S. Geological Survey, Washington, D. C.

Relations of Present Profiles and Geologic Structures in Desert Ranges. By Charles R. Keyes. From Bull. Geol. Soc. America, October 1910. Pp. 22. New York, 1910. Describes the character of mountain-forming agencies in the arid regions of the Southwest.

Deflation and the Relative Efficiencies of Erosional Processes Under Conditions of Aridity. By Charles R. Keyes. From Bull. Geol. Soc. America, October 1910. Pp. 36. Des Moines, 1910. An interesting discussion of the effect of erosion by the wind.

The Lake Superior Mining Institute's report of the fifteenth annual meeting, held on Gogebic Range, Michigan, August 24-26, 1910, is received. In it is printed the interesting and valuable papers read at the meeting.

A Central African Glacier of Triassic Age. By Sydney H. Ball and Millard K. Shaler. From *Journal of Geology*, November-December 1910. Pp. 24. Ill. Chicago, 1910.

Significance of Thrust-Planes in the Great Basin Ranges. By Charles R. Keyes. From the *Trans.* Iowa Academy of Science. Pp. 12. Des Moines, 1910.

The Ultimate Sources of Ores. By Charles R. Keyes. A paper read before the A. I. M. E., March, 1910. Pp. 24. Des Moines, 1910.

Oil Resources of California. By Mark L. Requa. Pp. 24. San Francisco, 1910. Notable resumé of the history, geology, and production of petroleum in California.

The Colorado School of Mines' biennial report for 1910 contains a paper on the non-metallic minerals of Colorado by John C. Bailar.

Zinc sheet, No. 9—18 by 81, drum, 100 lb.	9.50	10.50

CURRENT PRICES FOR ORES AND MINERALS

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked*.

	Min.	Max.
Antimony ore, 50%, per ton	*$20.00	$25.00
Arsenic, white, refined, per lb	0.02½	0.03
Arsenic, red, refined, per lb	0.07	0.08
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	42.50	47.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10% upward, per ton	*75.00	upward
Chrome ore, according to quality, per ton	10.00	15.00
China clay, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb	2.50	
Coke, foundry, per 2240 lb	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	
Magnesite, per M	190.00	
Silica, per M	47.50	
Flint pebbles for tube-mills, per 2240 lb	15.00	25.00
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	45.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	40.00	120.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	500.00	600.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per lb	0.02½	0.03½
Platinum, native, crude, per oz	25.00	30.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Tungsten ore, 65%, per ton	520.00	550.00
Vanadium ore, 15%, per ton	200.00	250.00
Wolframite (see tungsten ore).		
Zinc dust, 1400-lb. casks, per 100 lb.:		
Small lots	9.50	9.75
Large lots	7.50	8.50
Zinc ore, 50% up, per ton	*15.00	20.00

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

W. L. P., Ketchikan, Alaska: Barite.

M. D., Spokane, Washington: Black shale.

S. A. B., Fallon, Nevada: A soft earthy variety of limestone.

J. L. H., National City, California: The black cementing material is manganese dioxide.

J. A. H., Clifton, Arizona: No. 1, quartz; No. 2, volcanic ash; No. 3, rock stained black by the oxide of manganese.

F. A. L., Glenns Ferry, Idaho: No. 1, specular hematite which would hardly be of much value to work; No. 2, highly altered granitic rock; No. 3, garnetiferous sandstone having no connection with oil; No. 4, volcanic tuff; No. 5, chalcedony.

T. S. S., Pueblo, Mexico: The specimens appear to have come from a zone of contact between sandstone and intrusive masses of trachyte and syenite. They are various phases of quartzite and feldspathic veins. No. 1, quartzite; No. 2, greenish metamorphosed rock with zeolitic amygdaloids; No. 3, trachyte; No. 4, red orthoclase with dark segregations; No. 5, fine-grained syenite dike; No. 6, porous sandstone; No. 7, quartz; No. 8, silicious sandstone or quartzite with lighter bleached portions of the same rock; No. 9, contact specimen of baked rock; No. 10, orthoclase and quartz stringer with hematite; No. 11, quartzite; No. 12, chlorite schist; No. 13, feldspathic quartzite; No. 14, quartzite; No. 15, an altered porphyritic phase of syenite; No. 16, trachyte tuff; No. 17, contact of syenite with sandstone having lignitic seams; No. 18, a phase of the trachyte; No. 19, quartz with epidote and hematite; No. 20, core of orthoclase like No. 4; No. 21, black carbonaceous slate with fossil ammonites, possibly of Jurassic age; No. 22, trachyte.

COMMERCIAL PARAGRAPHS

N. B. Phelps, 405 Sheldon building, San Francisco, California, has been appointed representative of the Atlas Car & Mfg. Co., Cleveland, Ohio, which manufactures brick cars, electric cars, electric locomotives, mine cars, and the like.

The Geo. B. Adair & Son Co. has purchased the business of the Kilbourne & Clark Co., of Seattle, Washington. Among a number of agencies which it will handle is that of the Foos Gas Engine Co., of Springfield, Ohio. A large stock of engines will be carried.

The Griffin Co., San Francisco, announces that it succeeds the Western Engineering & Construction Co. in handling the agency for the Robins Conveying Belt Co. on the Pacific Coast. All the drawings and records of installations made through the Western Engineering & Construction Co. are in the hands of the new company, and therefore a continuity of service is assured.

Frederick G. Clapp has enlarged his geological engineering practice, and will now specialize in examining and reporting on coal in addition to oil, gas, and water. C. V. Gould, mining engineer, graduate of the Armstrong College of Science, Durham University, England, and for fourteen years coal expert in England and America, will take charge of this branch of the work. The general offices will be maintained at 331 Fourth avenue, Pittsburg, Pennsylvania.

The Wm. Powell Co., Cincinnati, Ohio, is shipping the Powell model Star valve on the contract with the Isthmian Canal Commission for all the globe and angle-valves up to and including 4 inches, for use in the construction work at Panama. The Powell Star valve was selected by the Board of Engineers in competition with valves of various other manufacturers as the best valve for the service desired. No change in construction or the metal formula used was required by the Commission to conform to the specifications, and this valve is precisely the same as the company is supplying to every user of the model Star valve.

TABLE OF CONTENTS

EDITORIAL

ANTIMONY is the latest metal to fall under the control of a European syndicate. Prices have already advanced from six to seven and a half cents per pound and a further increase is expected.

THE Cordilleran section of the Geological Society of America will meet at the University of California March 30, 31, and April 1, at the time of the meeting of the Pacific Association of Scientific Societies.

RAY CONSOLIDATED is expected to begin milling within the next ten days. Ore is already being delivered at the plant. The unit of the mill first started will have a capacity of 1000 tons. Mr. D. C. Jackling, Mr. Seeley W. Mudd, and their associates are to be congratulated on the completion of the first stage of a great work.

DAY LETTERS may now be sent by telegraph, and in conjunction with the night-letter service inaugurated a year ago, this gives Americans the cheap and satisfactory service so long demanded. The new owners of the Western Union Telegraph Company are taking the best possible means of overcoming that corporation's well earned and long standing unpopularity.

AGITATION for direct election of United States Senators will gain force as a result of the Senate vote on the case of Mr. Lorimer. There can be no escape from the logic of Mr. Root. Mr. Lorimer was elected as a result of corruption in the Legislature of Illinois and no one having personal knowledge of conditions there at the time will undertake to affirm that he could or would have been elected by popular vote.

COLORADO mining men are discussing the Joyce bill, now before the State legislature, which is designed to prevent discrimination between shippers and between districts in smelting rates. That there is discrimination is admitted, but it has always been held to be legitimate and necessary to the conduct of the business. The smelter manager must be able to adjust rates so as to call out different classes of ores in the proportion needed for economical smelting. The burden falls unequally on different shippers. To the extent that it does so because one sort of ore or another is locally more abundant, or is more cheaply mined, the inequality in smelting rate is due to natural causes. In individual cases an additional inequality has been created with the effect, if not for the purpose, of

forcing the sale of particular mines. Injustice of this sort has given force to the movement for State regulation of the industry. While frankly admitting the sporadic occurrence of such injustice in the past, we doubt the advisability of applying so radical a remedy.

ANNOUNCEMENT of the resignation of Mr. R. A. Ballinger as Secretary of the Interior has been received with universal approbation. The President's choice of Mr. Walter L. Fisher as his successor could not have been improved. Mr. Fisher is a young lawyer of proved ability and character, a man of the highest ideals, one who is a 'progressive' but who is level headed, and who can be relied upon to be accurate as well as enthusiastic.

'THEY order things differently' in Canada as well as in France. Indeed, in many things we might learn to advantage from our northern neighbors. The Dominion is about to have a Federal mining code, and in framing it the Ministry has accepted frankly and gladly the work of a committee of the Canadian Mining Institute. At Washington, when mining laws are under review, it is to a Heyburn, a Mondell, or a Carter that Congress turns for advice. A suggestion from a Raymond, a Channing, or a Winchell would probably be resented as an impertinence, if, indeed, an immediate search was not made for an axe and a grindstone.

AN INTERESTING CASE has recently arisen at Batopilas under the Mexican law of *injurias* or libel, as it is elsewhere called. Mr. Gillmore Goodland, an English mining engineer, director of the Batopilas Mining, Smelting & Refining Company, and of the Batopilas Mining Company, the New York corporation from which the former leases mines and mills, has been arrested and placed in jail on complaint of an ex-bookkeeper of the company. Mr. Goodland and Mr. A. R. Shepherd, Jr., were recently appointed by the directors to visit the properties and effect changes in methods of operation. In the course of these changes a number of men were discharged, including the complainant. Mr. Goodland wrote a private letter of discharge that forms the basis of the suit. The questions at issue are the conditions, if any, under which the employer can criticize the acts of an employee; whether such criticism may be expressed in a private letter addressed to the employee; and whether, in this particular case, the letter included anything that, correctly translated, constituted libel. It happens that under the Mexican code release under bond in such cases requires testimony from witnesses who can swear from personal knowledge that the accused has been of good conduct during the last five years. Naturally, such testimony is not often available in the case of a visiting engineer in a remote district, and the requirement has imposed hardship on Mr. Goodland. The matter will, of course, be fully investigated, but communications in Mexico have been much interrupted of late and prompt action by central authorities has been impossible. The whole situation is one that consulting engineers especially need to consider carefully.

The Problem of Nitrogen Supply

The complex relations of the traffic in the commodities that we daily use are tolerably familiar from constant association, and the general features of international trade relations—how the United States, for example, exports foodstuffs and machinery, and imports tea, sugar, silk, and wines—are matters of common knowledge. But a deeper analysis of these relations, an analysis of the traffic in the chemical elements, is one that few stop to make. A moment's consideration of how the supply of oxygen, hydrogen, nitrogen, iron, silicon, potassium, sodium, and the rest, needed by industrial operations, is secured and maintained, reveals a world of interest. Fortunately the supply of nearly all of them is plentiful and apparently almost inexhaustible; but two, nitrogen and potassium, present problems that possess an added importance for those engaged in the mining industry, for both enter into the composition of potassium cyanide.

All the simple salts of potassium are soluble, and in the decomposition of the rocks composing the earth's crust, one of two things happens; either the potassium salts are converted into complex insoluble silicates, of which the most important are the clays, or else are carried in solution into the ocean, and no economical method of recovering them from either source is yet known. Until the middle of the last century the potash industry was maintained by the recovery of the desired element from the ashes of vegetable matter, the plants having derived it from the soil. About fifty years ago there were discovered at Stassfurt, Germany, large deposits of potassium salts, apparently derived from the evaporation of sea water. Means of converting these salts into the forms desired in commerce were quickly devised, and so long as this supply remains unexhausted, no fears need be entertained, though by what method potassium can be obtained afterward is now entirely unknown. The military and commercial disadvantage of this complete dependence of the other great nations upon Germany for a supply of an important and necessary element deserves more extended comment than there is space for here.

A difficult problem is encountered in the obtaining of a supply of nitrogen, for the reason that, although the element is so abundant, it is so inert chemically that it can be made use of only through its compounds, the nitrates being the most important. These are very soluble salts, so that the chances of their accumulating in large deposits are remote indeed, the problem being further complicated by the fact that they are unstable and easily decomposed. Until the middle of the last century the supply of nitrogen was practically limited to that obtained from the oxidation of nitrogenous organic matter by the so-called nitrifying bacteria. About that time it was found that peculiar conditions in

Chile had given rise to the formation there of large deposits of sodium nitrate. A large industry quickly developed, twelve to fifteen million tons of sodium nitrate being annually imported into the United States alone from this source. More than one-half of this is used in the manufacture of explosives, some 17% in the production of fertilizers, 15% in general chemical industries (photographic films and celluloid may be mentioned as examples of the many products containing nitrogen), some 11% in the acid industry, and the remaining 5% is mostly used in the making of glass. The disadvantage of being obliged to depend upon a single country for our nitrogen supply is obvious, and still more important is the fact that the most optimistic estimates of the available supply point to its exhaustion within the next three hundred years, with a corresponding increase in cost before the end of that period. Research into other possibilities has therefore been correspondingly stimulated.

The supply of cyanides has until recently been obtained in an indirect way by the reduction of ferrocyanides obtained in gas and coke manufacture, the nitrogen in the coal yielding ferrocyanides and ammonia by distillation. Germany leads in the production of this chemical, as by-product coke-oven practice is most highly developed there. The production of nitrogen compounds from the nitrogen of the atmosphere has been attempted in three different ways—the direct manufacture of nitric acid, the direct production of potassium cyanide, and the production of cyanamid. The attempt to directly produce potassium cyanide has not been a success, but the first method has been reasonably successful, and the last entirely so. Direct production of nitric acid by passing heated air through a flaming arc is technically a complete success, but is possible only where electric energy is plentiful and cheap. The production of cyanamid is effected by passing nitrogen gas over heated calcium carbide, with the resultant formation of calcium cyanamid and graphite. More than a dozen plants for the production of this salt are in operation in Europe, and one, at least, in America. The product, as placed on the market, is an indefinite mixture of cyanamid, lime, graphite, and undecomposed carbide. The industry is as yet too new (most of the plants having been in operation less than two years) to make accurate forecasts as to its effect upon commerce in cyanides and other nitrogen salts. So far, it has been found necessary to use pure nitrogen to pass over the carbide; if producer-gas could be used for this purpose, the cost of the product would be much decreased. This at least may be said, that two practicable methods of forming nitrogen salts direct from the great nitrogen supply of our atmosphere have been devised, so that the cost of obtaining nitrogen salts will certainly not increase, and in all probability will considerably decrease. Even more recently a process has been devised for using calcium cyanamid in cyanide solutions without first forming the cyanide, so it may reasonably be expected that the cost of the salts used in cyaniding gold ores will decrease materially during the next few years. And the change from an indirect supply of nitrogen salts from sources situated in other countries to a direct supply from inexhaustible sources within our own borders, is a noteworthy step in the progress of chemical industry.

Tenabo Mining & Smelting Company

In commenting November 19 upon the sale of American mining securities in France, we reflected unfairly, as we now discover, upon the Tenabo Mining & Smelting Company. This corporation is not engaged in re-opening the old mines near Tenabo, as we had been informed, but is developing new and promising properties located in 1905. The attempt to sell stock on the New York curb was made by an individual shareholder and was not on behalf of the company. The officers of the Tenabo Mining & Smelting Company, well-known bankers and attorneys at Salt Lake, have courteously supplied us with a report on the property made in 1908 by Mr. Duncan MacVichie. He found developed at the time, 7783 tons of smelting ore having a net value of $13.38 per ton, and 17,257 tons of concentrating ore estimated at $3.88 per ton. In addition, there was an excellent prospect of finding additional ore, Mr. MacVichie expressing the opinion that an expenditure of $20,000 to $25,000 would bring the reserves up to 100,000 tons. It is evident that such a property is one of great promise and falls within the class of "legitimate undertakings greatly to be encouraged." Whether, none the less, it is sound policy to offer securities based upon such an undertaking, to French investors, is a matter for legitimate difference of opinion. A stock or bond may constitute an excellent purchase for an engineer who keeps in touch with active affairs, and yet not be suitable for the investment of trust funds. On the contrary, the low rate of interest paid by many sound securities makes them poor investments for those who can spare the time and skill necessary to watch higher paying but more speculative securities. In other words, there are, and should be, different markets for different kinds of securities. We believe that it is better to sell to the French the possibly less remunerative but more certain securities that represent established concerns. Speculative enterprises are best financed by those living near the scene of the industry, or by those who make a specialty of the particular business. A single failure—and failures must be accepted along with successes—will hurt American credit in an otherwise good market quite as much as the famous shipment of low-grade bicycles to Germany hurt export trade in machinery. On the other hand, we would heartily commend investment in mines during development, on the part of people here at home, and particularly for those familiar with mining. We hope the Tenabo may prove to be one of the great copper mines of America. There are evidently many reasons for believing that it may, but we believe it would be better policy to carry it further on domestic capital and not invite French participation till later.

Mining in the San Juan—V

By William H. Storms

A high, rugged mountain range divides Ouray from San Miguel eounty. Just over the erest of this range above the Virginius (Revenue tunnel), Camp Bird, and Atlas mines, are the famous mines of the Telluride region. The most noted of these are the Smuggler-Union, Tomboy, Liberty Bell, and Japan-Flora groups. There are several others less noted. The geology and vein structure of the mines of this district have been so frequently described heretofore, notably by T. A. Rickard in the *Mining and Scientific Press*, in the *Transactions* of the Ameriean Institute of Mining Engineers, and elsewhere, that it seems unneeessary to repeat the deseription here. The town of Telluride, like Ouray, is situated in the bottom of a eanyon deeply eroded in the voleanic and sedimentary roeks whieh ehiefly comprise the San Juan mountains. The mines are high above the town in the several glaeial ampitheatres, ealled basins. The Liberty Bell is in Cornett basin, the Tomboy

Taking Lumber up to the Tomboy Mine.

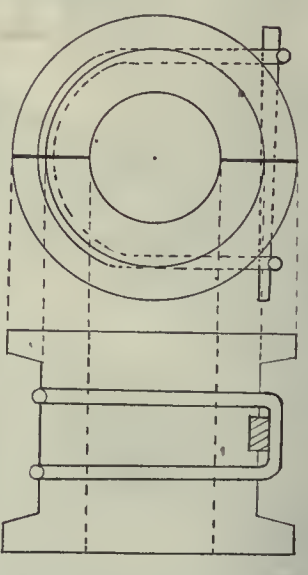
in Savage basin, the Smuggler-Union in Marshall basin, the Atlas in Silver basin, and the Camp Bird in Imogene basin. These basins are rudely eireular and are almost surrounded by towering eliffs of lava, whieh rise from 1000 to nearly 3000 ft. above their relatively level floors. The mills of the Liberty Bell and Smuggler-Union mines are situated down in the eanyon of the San Miguel river, in the southern outskirts of the town of Telluride; those of the Tomboy and Japan-Flora are at the mines in Savage basin. Some smaller mills are at intermediate points in the steep side eanyons, sueh, for instanee, as the Valley View, Cimarron, and Columbia mills. Transportation of ore is mostly by means of aerial ropeways, although there are some good roads and excellent trails. The road from Telluride to Savage basin is four miles long and was built by the eounty at an expense of $50,000. In many plaees it is eut in the solid roek, in others great rip-rapped eribs of timber maintain the roadway in plaee. At one point on this road from Telluride to the Smuggler-Union mine the road has been eut through a tunnel where it passes around a jutting spur of roek. The engineering features of these roadways must be seen to be appreeiated. Wagons travel over these mountain roads, though most of the freighting is done by means of paek animals, long lines of which may be seen almost any day slowly ereeping along the faee of the mountain, aseending or deseending the ribbon-like road. The aeeompanying illustration shows how most of the lumber is taken from town up to the mines. When eovered with snow, traveling on these roads beeomes extremely dangerous. Supplies are also sent up to the mines on the rope-ways, and not infrequently men travel in the buekets, notwithstanding that there is an ever present element of danger. This, perhaps, is no greater than riding on skips and eages in mine shafts. The danger of riding in the tramway buekets only seems more evident. There are many miners for whom the deepest mine workings have no terrors, but who are timid if elevated a few feet above the ground.

The famous Smuggler-Union mine with its great produetion and interesting history was being worked by a system of leases at the time of my visit to the distriet. Owing to laek of time I was unable to inspeet the underground workings, whieh are very extensive, and I spent only a short time in the neighboring Tomboy mine, whieh is about 3000 ft. southeast of the former. The Tomboy vein is reaehed through an adit whieh strikes the vein at what is known as the 1650-ft. level, the datum being a level in one of the neighboring ridges where the vein outerops. The mine has been worked for years through a number of adits driven on the veins at various levels. A shaft from the surfaee passes the adit at the 1650-ft. level and has been sunk 450 ft. below it, to the 2100-ft. level. Adits or levels have been opened at 350, 500, 650, 800, 1050, 1200. 1350, 1500, 1750, 1900, and 2100 ft. below the surface. The shaft is an ineline following the vein and dips at an angle of 73°. Present mining praetiee is to drive a drift on the vein, which is about 5 ft. wide, and to eut raises at every 20 to 25 ft., building strong ehutes at the foot of eaeh raise. Manways are provided at eaeh 100 ft. The main gangways are not timbered exeept where loose ground requires it. The stopes are opened from the several raises in ore, leaving a solid bloek of ground between each ehute over the baek of the level. As stoping progresses upward only about one-third of the ore broken is drawn off. This permits the miner to keep within easy reaeh of the ore overhead until the stope is worked out, and also makes available a large tonnage of broken ore in the mine to be drawn upon as oeeasion demands. It furthermore renders the mine workings safe, until the ore is withdrawn, when if the roek walls collapse no damage is done. The solid bloek of ore left between the bottom of the stope and the gangway may be removed at any time after the ore is entirely withdrawn from the stope above, by ehuting it down into the level and shoveling it into ears, or it may be taken down when the stope earried up from the level next below is broken through. In the latter ease the shoveling eost may be saved, as the ore ean be drawn out of the stope into cars through the

Telluride, Colorado.

Smuggler-Union Mines, Telluride, Colorado.

chutes, but if this latter plan is adopted the level should first be cleared of tracks, timbers, and all débris and the rock shot down before the stope below is holed through into the gangway. This saves much annoyance and loss of time when drawing off the ore through the lower chutes. In the Tomboy mine the original Tomboy vein has been exhausted and stoping operations are now almost wholly confined to the Argentine vein, a comparatively recent acquisition. All the ore from the present workings passes out through the main adit, which is on the level of the breaker floor of the mill. The cars are made up into trains that are moved by electric motor. The ore on reaching the mill is dumped on an 8-in. grizzly, the oversize being broken with hammers to pass the grizzly. From here it goes to a large Gates breaker and is delivered to the mill-bins by a belt-conveyor that is fitted with an automatic tripper which distributes the ore wherever desired. From the bin the ore passes by chutes to suspended feeders. The mill has 60 stamps of 1050 lb. which drop 10 in. 100 times per minute. The Tyler Ton-cap 18-mesh screen is in use. The capacity of the mill is 350 tons per day—nearly 6 tons per stamp. This high capacity is due partly to the rather coarse screen and to the large area of discharge surface of the mill screen, which is 10 in. high; also in part to the character of the ore. From the mortars the pulp flows over amalgamated silver-plated copper plates that are set at a steep grade, rendered necessary by the large amount of sulphides in the ore. The sulphides are mostly galena, blende, pyrite, and chalcopyrite. Rhodonite, quartz, and calcite are also present. The mill foreman stated that 50% of the gold and silver is saved by amalgamation. From the amalgamating tables the pulp passes through mercury-traps, and from these goes to a Fernier pump that elevates it to a large spitzkasten. The overflow from the spitzkasten goes to three Callow tanks; the bottom discharge going to Richards classifiers (two for the 60 stamps). The overflow from the Callow tanks goes to six vanners and the coarse to six other vanners, each set adjusted to treat the material coming to it. From the Richards classifiers the material from the first compartment goes to two slime-tables, the remainder to twelve Wilfleys. The slime from all tables and vanners goes to slime-pump by launder, and thence to Callows before six vanners. The lead concentrate from the vanners is re-cleaned on one Wilfley. The concentrate is sent by conveyor to a Frenier pump which elevates it to de-watering cars that dump automatically. The concentrated mineral then passes through an Argall drier, is conveyed by a belt scraper to a Wilfley drier, in which it is rabbled to the farther end and thence elevated to the top of a vertical desulphurizing furnace, thence through a water-jacketed cooler, after which it is elevated to a Ding electro-magnetic separator in which the iron and zinc minerals are separated. The galena concentrate from the re-cleaning Wilfley is carried by a conveyor of the Cananea type to a launder which discharges to an elevating pump that raises it to dewatering cars, from which it passes through a Wilfley drier, and from this latter to bins where it is sacked for shipment. Thus, it will be seen that the products of this elaborate mill scheme are: Amalgam from the plates and traps, a clean lead sulphide, and separate concentrates each of iron and zinc sulphide. I am under obligations to D. A. Herron, general manager of the Tomboy mine, for various courtesies shown me both at Telluride and at the mine.



Feed-Tappet Smuggler-Union Mill

Pandora is the name given the little village that has grown up about the Smuggler-Union mills, a mile south of the town of Telluride. The Liberty Bell mill is situated about midway between Pandora and Telluride. These mills are connected with the mines up in the basins, several thousand feet above, by aerial tramways. The mountains rise in tremendous cliffs—a succession of picturesque terraces. Here and there beautiful cascades lend enchantment to the scene, which is still further enhanced by the coloring of the rocks. The scenery is grand and awe-inspiring, some might say sublime, but the beauty and sentiment of it all is wholly lost on these mining people of the San Juan, who in their eager quest for gold and for silver, have done wonderful things. For years the great mills have been sending forth an incessant roar, which, mingling with that of the water-falls, rises with a never ceasing murmur from the bottom of the deep canyon. Ever and anon the muffled boom of a blast far underground reaches the surface and reverberates from cliff to cliff, but is quickly lost in that vast wilderness of peaks and crags far up above the timber-line. It is truly a wonderful country, and affords splendid examples of the boldness, energy, and skill of the engineers who have successfully overcome the great obstacles nature has interposed in the pathway to easy success. The noisy waterfalls have been turned aside and made to drive water-wheels, supplying the mines and mills with power; frightful yawning chasms amid inaccessible cliffs have been spanned with ropes of steel which look like the strands of a spider's web far overhead. Gravity has been utilized as a means of generating power by applying the excess energy in the running ropes of the aerial tramways, to the driving of machinery. Splendid roads have been hewn in the solid rocks. It has been a great fight, and in it engineering science has won—not easily, but it has won. How best to overcome such difficulties is a great economic study; a problem which each mine manager, aided by his staff of engineers, must solve for himself. In seeking the solution he must consider every condition, every contingency, almost every possibility of the future. The manager

of the Tomboy thought it good business to build his mill up in Savage basin at the mine. All supplies are packed up to it on animals or freighted in

Tomboy Mine.

wagons up the $50,000 road. He is not harassed by the expensive up-keep of an aerial tramway like his neighbors. He had a good millsite available at the mine and made use of it. A good millsite just where you want it in the San Juan mountains is not always available. The Smuggler-Union mine being in a somewhat different situation, overlooking a precipice which plunges down so steeply that there is no dump, the management there considered it good business to build the mills down in the canyon, where the railroad runs through the mill-yard, and the mine is reached by aerial tramways. The rope-way is direct, for the mine can be seen from the millsite. The Liberty Bell mill is also at the foot of the mountain and is connected with the mine by a Bleichert tramway, though mine and mill are not within sight of each other.

Liberty Bell Mill.

Cliffs intervene and there is also a change in the alignment of the rope-way. In every case some way has been found to overcome each difficulty interposed by nature. The one thing most disquieting and seemingly more difficult of solution than all of the others, is the labor problem, but even this seems to have been solved in a manner which for several years past has permitted the uninterrupted operation of the mines and mills. There are occasional instances of ore-stealing and of mill theft, but they are rare.

As was stated in a former paper, the ores in the various mines of the San Juan differ greatly in character, which is all the more remarkable when it is considered that the fissures traverse the same rock formations. However, it is not intended to discuss here the genesis of these veins, but to refer briefly to the metallurgical treatment the ores receive in the several mills. The ore of the Liberty Bell mine is very hard, consisting of quartz generally accompanied by calcite, with usually much manganese dioxide. A great deal of clay also occurs in the vein, which it is impossible to keep

Smuggler-Union Mills.

separate from the ore going to the mill without expensive washing. The sulphide mineral is almost exclusively pyrite; galena, blende, or copper sulphides being rarely seen. In this respect the ore of the Liberty Bell is rather remarkable, being unlike that of any of the other mines of the region, excepting possibly an occasional local occurrence. The ore is delivered at the mill from the mine by aerial tramway, 80 buckets arriving per hour, 400 tons being the mill's daily capacity. From the breakers the ore goes to the mill-bins and from these passes by chutes to suspended feeders, that are actuated by a friction device known as the Hooper feeder-action, the invention of one of the millmen. The mill is equipped with 80 stamps weighing 850 lb. each, which drop 7 in. 100 times per minute. The screen used is the Tyler $^3/_{16}$-mesh Ton-cap. Crushing is done in weak cyanide solution and amalgamation is accomplished on a run of 7½ ft. of sil-

vered copper plates of the usual width, and divided into three sections by drops of ½ in. It would seem, judging from amalgamating practice generally, that a longer run of plates would be of value in increasing the amount of gold that may be saved by amalgamation. It is found that the cyanide corrodes the copper plates rapidly, their usefulness being limited to four or five months. In this mill the line-shaft is on the cam-floor, resting on the front knees, the belt-drive being horizontal.

From the amalgamating tables the pulp goes to five 5-ft. cones, from which the underflow and overflow go to separate Wilfleys. W. E. Tracy, the mill superintendent, has made what he considers a great improvement in the Wilfleys by tacking onto the tables three strips of wood which extend, like the Wilfley riffles, lengthwise of the table. The Tracy riffles are about twice the height of the Wilfley riffles and also somewhat broader. They divide the table into four longitudinal areas, and it is claimed by Mr. Tracy that the addition of these strips results in greatly increasing the capacity of the table, besides making it possible to secure a much cleaner concentrate, and higher saving—something well worth knowing. The concentrate is gold and silver-bearing pyrite. The middling from the Wilfleys is united, screened in a Bunker Hill conical screen, and the coarse sand is re-treated on another set of Wilfleys, the fine going to the settlers. The coarse tailing from the first Wilfleys goes to tube-mills, where it is ground and again amalgamated. The Wilfleys treating the overflow from the 5-ft. cones send their tailing to the settlers, where it joins that from the tube-mills. The consistence of the pulp at this stage is 6 or 7 to 1. In these settlers, which are circular tanks 33 ft. diam. and 10 ft. deep, are four stirring arms provided with sheet-iron rabbles. These arms revolve six times an hour, imparting a slow rotary motion to the pulp, which in consequence collects in the form of a broad flat cone about the centre, providing a somewhat thickened feed, which can be controlled. This goes to Pachuca-tank agitators, thence to storage vats in which the Moore filter is immersed. The time required to complete the cycle of operations with the Moore filter is 2 hr.—1 hr. filling, when the filter is lifted and lowered into the second vat, where it is given a strong solution wash for 30 min., followed by a weak-solution wash for 20 min. The cake is then blown off with weak solution under pressure. The sludge is discharged into the creek. The concentrate recovered is shipped to the smelter at Durango. Just prior to my visit to the Liberty Bell mill it was deemed advisable to remove the old wooden blocks from beneath the mortars, and to replace them with concrete blocks. The change of the first unit of 10 stamps had been made. The 10 stamps were hung up and removed, the mortars shifted to a crib of timbers in front of the battery, the old wooden blocks torn out and the new concrete blocks built and the mortars replaced in position on them. This was all accomplished within five days of the date of hanging up the 10 stamps—a record-breaking performance, I believe, of its kind.

W. H. Staver, manager for the Liberty Bell company, afforded me every opportunity to inspect the property and aided me in various ways. I am also indebted to W. E. Tracy, the mill superintendent for his courtesy.

At Pandora the Smuggler-Union has two mills. The east mill is equipped with 80 stamps, the west mill with 60. The stamps weigh 1050 lb. and drop 6 in. 100 times per minute. A Tyler 14-mesh Toncap screen is used and the discharge has been lowered to the level of the top of the dies. The amount of ore crushed per stamp daily has averaged 4⅞ tons for the past year. Amalgamation is accomplished entirely outside the batteries, no quicksilver being fed inside the mortars. The mine, both the Smuggler-Union and the Pandora vein, is being worked by a system of leases, in consequence of which the mills are arranged to crush in units of 5 stamps each. This permits a segregation of the numerous separate lots of ore coming from the various leases. There are no features of unusual interest in these mills. The ore comes from the rock-breakers to the mill-bins and passes by chutes to the feeders in the usual manner. I noticed one innovation in the stamp-battery in the form of a sectional feeder-tappet. This is secured to the centre stamp-stem just above the top of the mortar. The tappet is cast in the same form as the cam tappets, but is not so wide and is but 6 in. high. It is split, and when placed about the stamp stem is encircled by what may be described as a 'double-U' clamp which is tightened by a long wedge, as shown in the sketch on the preceding page.

After crushing by stamps the sand and slime are separated by classifying cones and the sand is delivered to tanks by means of Butters distributers. Solution is turned on and leaching proceeds for ten days, when the tanks are drained and the sand is shoveled through bottom gates to a second tier of tanks immediately beneath the first. In these leaching is continued for a further 8 or 10 days. The sand is then discharged to a waste launder which carries it to the creek. The slime from the classifying cones goes to a canvas plant of the Gates type. This canvas-plant is the unusual feature of the metallurgical practice at these mills. It consists of 106 inclined planes each 10 ft. wide and 12 ft. long covered with canvas. The slime from the cyanide plant is delivered to a series of 98 of these canvas tables. The tailing from the tables goes to pointed boxes, the bottom discharge from which is sent to 4 vanners (2 Frue and 2 Gates), a Wilfley taking the coarser discharge. Tailing from all machines goes to a lower line of 8 canvas-tables. The pulp is allowed to flow over the canvas for 45 minutes, when the feed is diverted to an extra table and clear water turned on, after which the tables are washed clean with a flat spray, this requiring 15 minutes to each table. P. H. Nelson is in charge of the canvas-plant and has reduced its operation to a science. The manager, Bulkley Wells, was absent at the time of my visit, but I was shown every courtesy by A. D. Snodgrass, assistant manager,

who gave me the freedom of the plant. Walter Reed is superintendent of the cyanide plant. I found him in the midst of a clean-up, with thousands of dollars worth of precipitate to handle, and he was at the moment, the busiest man on the job. The cyanide practice, Mr. Reed told me, was in no manner different from that described some time since by T. A. Rickard in the *Mining and Scientific Press.*

The Japan-Flora mine is in Savage basin and adjoins the Tomboy. It is comparatively a new mine, but seems to be destined to become one of the great properties of the district. A mine cannot be made in a day, nor yet in a single year in the San Juan. The Japan-Flora is operated through a shaft and is equipped with a concentrating mill consisting of rockbreaker, rolls, trommels, jigs, and concentrators. The manager is Mr. Wolfe.

Two and a half miles east of Telluride, in Ingram basin, is the Black Bear mine, said to be developing into a valuable property. It is owned and operated by a local company largely composed of Finlanders, many of whom are practical miners. The mine is operated through adits, and is equipped with a mill. Between the Liberty Bell and the Smuggler-Union mills is the mill of the Mayflower company, whose mine is 3 or 4 miles distant in Gray's basin. An aerial tramway connects mine and mill, both of which have been idle for some time. A mile and a half west of Telluride and about 1000 ft. above the San Miguel river is the old Boomerang mine, from which considerable ore was shipped in the early days of the camp. The ore in this mine occurs in flat deposits in the limestone, and carries, besides gold and silver, the sulphides of lead, iron, zinc, and copper, and also the secondary products of the oxidation of these sulphides. An aerial tramway which at one time transferred the ore from the mine down to the railroad track at the base of the hill has been removed, and the mine has long been idle, the ore being too low grade to afford a profit. I was also told that the orebody was cut by a fault and not rediscovered. The workings are now caved. There are a number of small mines about Telluride which with sufficient capital and experienced management would undoubtedly become profitable. The pioneering has all been done, the methods of metallurgical treatment worked out, and there is no longer any unusual risk attending mining operations in the San Juan region.

Potash is an abundant constituent of many rocks and minerals found in the United States, and experiments have lately been made to devise means of profitably extracting it from the rocks. The waters of some Western lakes, as Owens and Mono lakes, California, also contain potash and indicate that the beds of evaporated lakes in the desert regions of California and other States may include large amounts of potash. Potassium nitrate has been found in the desert region northeast of Salton, California. Congress has just appropriated money for a special investigation of potash deposits, to be made by the Geological Survey.

Dome Mines Mill

*The following is a general outline of the plant which is being built by the Dome Mines Syndicate at Porcupine, Ontario. The ore, which is essentially quartz and greenstone schist, carrying free gold and iron pyrite, was at first considered to be an ideal concentrating ore. The gold was closely associated with the iron pyrite, and a high-grade concentrate could be obtained. The tailing, however, was sufficiently valuable to warrant cyaniding. By regrinding the concentrate, it was found that a large percentage of the gold could be recovered by amalgamation. The idea of concentration was then abandoned and experimental work was confined to sliming the whole product by two-stage crushing, amalgamating after each, and cyaniding the tailing. By grinding to 90% through a 200-mesh screen, 84% of the gold was recovered by amalgamation. The ore was particularly free from cyanicides, the only difficulty arising from the presence of a small amount of carbonaceous material which caused a secondary precipitation. This was overcome by lengthening the period of agitation.

The mill, which was designed by the Merrill Metallurgical Co., is to be electrically driven and will be built in units of ten stamps each; four units being installed at once. A gravity plant will be obtained by making four drops from crusher to tailing discharge. Preliminary crushing will be done in two stages, using No. 7½ and No. 5 Kennedy gyratory crushers. Belt-conveyors will carry the ore to the stamp-feed bins. Chalmers & Williams 1250-lb. gravity stamps will be used with straight-back, rapid-discharge type mortars, screen 18-mesh or coarser. The foundations will be reinforced concrete. Outside amalgamation will be adopted. Superimposed Dorr drag-classifiers will be installed over tube-mills of the El Oro type, which will be followed by a second set of amalgamating plates. Hydraulic cone-classifiers will discharge back to tube-mills and overflow to Dorr thickeners. Agitation will be accomplished in a series of continuous Pachucas. Combined thickeners and press tanks will feed to Merrill slime-presses which will discharge through automatic tailing samplers.

The gold will be precipitated by the Merrill zinc-dust process. The zinc-dust will be fed to a short conveyor-belt, operated by means of floats and counter-weights, at a rate proportional to the volume of solution pumped from the tank. The zinc-dust will be discharged into a mixing cone and the emulsion agitated by a jet of air. A small stream of barren solution will provide a constant overflow which will carry the emulsion down a pipe to the suction of the pump. The solution will be pumped to triangular precipitating presses, precipitation taking place entirely during the passage of the solution through the pump, pump-column, and presses. The precipitates will be acid-treated, fluxed, and smelted.

---

*Abstract from the *Canadian Mining Journal.*

Silver in Sulphocyanate Determinations

By E. M. Hamilton

The following notes deal with facts that are no doubt well known in general chemistry, but their relation to some of the standard methods recommended for analysis of cyanide plant solutions is apt to be overlooked; therefore, a short account of a recent personal experience may be useful to others, especially since most writers on the chemistry of cyanide solutions have not mentioned these points.

In the course of an examination of some solution resulting from the treatment of concentrate, I used the method most commonly given for the determination of sulphocyanate; that of titrating with permanganate after removal of the ferrocyanide by precipitation as prussian blue. The solution contained 0.5% free cyanide, 0.1% free alkali (in terms of CaO), no zinc, and about 80 oz. of silver per ton. Acidifying with sulphuric acid produced a heavy precipitate of silver which was filtered out before proceeding farther. On addition of ferric chloride to the filtrate, no prussian blue was formed, and there was no indication of sulphocyanate. The operation was then repeated, using hydrochloric acid instead of sulphuric, with the result that 0.1% KCNS was indicated on titration with permanganate, but prussian blue remained absent.

After trying a number of experiments with made-up solutions I concluded that in the case of the sulphuric acid the sulphocyanate was taken up by the silver and filtered out in the precipitate. To test this, 50 c.c. of the made-up solution, containing 0.044% KCNS, was acidified with H_2SO_4 and filtered; the precipitate and filter paper were well washed with hot water and the washings added to the filtrate, which was then titrated and gave 0.001% KCNS. The precipitate was redissolved in 100 c.c. of 0.5% cyanide solution, agitated with zinc-dust, filtered, the filtrate acidified with H_2SO_4 and titrated, giving 0.0432% KCNS. This, added to what was found in the filtrate, made a total of 0.0442% KCNS. and showed that the deficiency (amounting to almost the whole of the KCNS originally present) was held in the silver precipitate. The experiment was repeated, using HCl instead of H_2SO_4, with the result that there was obtained in the filtrate 0.042%; obtained by redissolving precipitate 0.002%; or a total of 0.044% KCNS. It would thus seem that the results of acidifying with sulphuric acid are only produced to a very slight extent with hydrochloric.

Following this, experiments were made by adding previously prepared and well washed precipiates of AgCN and AgCl separately to a solution of KCNS in distilled water. In the case of AgCN only a trace of sulphocyanate was found in the filtrate while the parallel test with AgCl showed 0.011% KCNS out of a total of 0.0537%. It was thus evident that silver in both these forms would combine with sulphocyanate in solution, and the question arose, why was this result apparent to such a slight extent in the original tests on the made-up solution when HCl was used for acidification? The only difference seemed to lie in the presence or absence of free HCl, so to the previously prepared silver chloride precipitate a little HCl was added before agitating with the KCNS solution (0.049% by titration). The filtrate from the above agitation gave 0.05% KCNS, and showed that the presence of free HCl had prevented the AgCl from reacting with the sulphocyanate.

The conclusions to be drawn would seem to be: (1) When acidifying a cyanide solution containing silver with sulphuric acid, preparatory to titration with permanganate for potassium sulphocyanate, the silver reacts with any KCNS present, converting it into sulphocyanate of silver, which is filtered out and thus removed from the sphere of titration. (2) Although silver chloride will also react with KCNS to form AgCNS, yet this interference is almost entirely prevented by having free HCl present, so that if the permanganate method be chosen practically accurate results may be obtained by using hydrochloric acid instead of sulphuric.* (3) Correct results may be obtained with sulphuric acid after first removing the silver from the solution by precipitation with zinc-dust.

In regard to the latter method, however, there is a point to be observed. When ferrocyanide is present and it is desired to estimate this by separation as prussian blue, the zinc taken up in the precipitation will throw down the ferrocyanogen as zinc ferrocyanide on acidifying the solution, so that on addition of a ferric salt no prussian blue will be formed. This result can probably be minimized by pouring the solution to be tested into a previously acidified solution of ferric salt, as explained by Clennell ('Chemistry of Cyanide Solutions'). A similar reaction takes place, only in a less degree, in the presence of silver, for on taking a made-up solution containing about 80 oz. of silver per ton, 0.1% KCNS, 0.04% $K_4Fe(CN)_6$, 0.5% free cyanide, and 0.1% CaO, and precipitating the silver with HCl, not a trace of prussian blue was formed on addition of ferric chloride to the filtrate. When the percentage of $K_4Fe(CN)_6$ in this solution was increased above 0.04% and the operation repeated, some prussian blue was thrown down. For sulphocyanate determinations alone, I have found the permanganate method gives concordant results, and when ferrocyanide is present it appears to make no difference whether this is eliminated as prussian blue, or as zinc or silver ferrocyanide, provided that the precipitate and filter paper are thoroughly washed. But if, at the same time, indications of ferrocyanides are being watched for, and if silver is present or if zinc-dust has been used to remove the silver, the absence of prussian blue in the filtrate on adding

*Sutton, Volumetric Analysis, 'Precautions in titrating with permanganate', points out that if HCl be used it should be very dilute to avoid vitiating the result by liberation of chlorine.

a ferric salt can not be taken as evidence that there was no $K_4Fe(CN)_6$ originally present in that solution.

To sum up, it would appear that the simplest procedure for determining sulphocyanate in presence of silver is by acidifying with hydrochloric acid. It should be first ascertained by preliminary trial about how many cubic centimetres of HCl are needed to precipitate the silver and to leave a small excess of acid to act as a protective for the KCNS. Then the necessary quantity should be placed in a beaker and a measured amount of the solution to be tested added to it, and the silver precipitate filtered out. An aliquot portion of the filtrate may then be taken, and ferrocyanide (if still present) removed by addition of ferric chloride, care being taken that the precipitate and filter paper are thoroughly washed. The filtrate and washings should then be further acidified, if not already sufficiently acid for purposes of the titration (avoiding an unnecessary excess), and the permanganate test proceeded with in the usual way.

SAN JUAN OILFIELD, UTAH

Nearly 10,000 claims have been filed for locations in the San Juan oilfield, Utah, during the last few years. Development has not, however, kept pace with the filing of the claims, for although a great deal of drilling has been done, most of it has been unskilful and strings of tools have been lost in many of the drill-holes sunk. As a result, although 25 wells have been drilled, none are yet producing commercially. Oil was found, however, in nearly every place where drilling was attempted, and in the opinion of H. E. Gregory, of the United States Geological Survey, whose report on the field is published as a part of the Survey's Bulletin 431-A, now available for distribution, several of the wells already sunk are likely to prove profitable.

The field is promising, according to the report, although the task of providing labor, fuel, and transportation is difficult. The region is arid. The nearest coal beds are in the Durango field, in Colorado, 100 miles to the east, and in the Navajo Reservation, 60 miles south. Labor will probably have to be brought in, though the Navajo Indians are intelligent and efficient workmen. As a solution of the transportation problem the report suggests a pipeline along the Chinlee Wash to Ganado, thence to Holbrook and the railroads. Over this route oil would flow by gravity for half the distance. It is not likely that there will be a market for the oil near the field. Most of the drilling has been done along Limestone creek. Prospectors have found eight distinct oil-bearing sands, but in no place where drilling has been attempted have the three lowest sands been touched as yet. Oil-seeps along the San Juan river have been known for years. The first well was sunk in 1907 and oil was struck in March 1908, and development since then has been rapid. In 20 of the 25 wells sunk oil of good quality has been found, but as yet there has been no commercial production. The public land in that part of the field that lies north of San Juan river was withdrawn from entry in October 1909.

Mohave County, Arizona

By R. H. Toll

Mohave county is again attracting attention as a metal-producer, and the several camps are entertaining engineers and investors, though not yet in sufficient numbers to crowd the county, for it is very large and much of its space is still given over to jack-rabbits and rattlers.

The mining camps are reached by way of Kingman, a thriving town of 800 inhabitants, on the main line of the Santa Fé railroad, near the western border of Arizona. The principal business of this little city is being the county seat; a distinction which it enjoys for the reason that there is no other town in the county to contend for the honor, the only other communities being mining camps that are too busy for politics. Aside from politicians, Kingman produces nothing, the surrounding district being rough, rugged, and rocky, and the only vegetation such thorny stuff as a boulder-strewn desert will produce. But, in the hills, at a distance of 12 to 60 miles to the west and north, are many mines of many metals, and the county seat has one characteristic in common with ancient Rome, for all roads lead to Kingman. Hence it is the supply-point of the entire county, through which advantage it naturally derives much revenue. Recently Kingman has taken to supplying even the power for the mines, and its electric-power lines have been quite a factor in stimulating activity in the gold-mining belt by greatly reducing the cost of power. It is said that formerly the Gold Road mine alone expended annually $90,000 to $120,000 for power generated by gasoline engines.

The county is not booming, by any means, and some of its camps have lost in population; for instance, Chloride, which ten years ago boasted 2000 inhabitants, who have gradually faded away until now barely one hundred souls and two Chinamen remain. When, however, a district possesses a mine as rich as the Gold Road, and another which produces approximately $50,000 per month with a 10-stamp mill, as the Tom Reed has been doing, mining men begin to 'sit up and take notice'; and the success of these two gold mines has led to renewed efforts in their vicinity which may be expected to result in further interesting developments, for there are other properties on which the showing is probably equally as good as on the two mines mentioned, at the same stage of development.

A brief description of the Gold Road mine will suffice, as others have already appeared. It is situated on the western slope of the River range, also called the Gold range, about 24 miles southwest of Kingman. Tertiary volcanic rocks prevail, practically constituting the range, though overlain in places by rhyolite and younger basalt. The veins are of two main types, those in which the vein filling is chiefly quartz and adularia, and those in which it is chiefly calcite. According to F. C. Schrader, to whose report I am indebted for much of

this information regarding the geology of the county, the former type seems to be the older and to carry the better ore, occurring mostly in undifferentiated volcanic rocks. Veins of the latter type occur chiefly in green chloritic andesite and trend nearly north. The vein is wide and may be followed on the surface for a distance of a mile and a quarter. It has been developed underground for a distance of about 2200 ft., of which 1700 ft. is said to be ore, of an average value of over $9 per ton. Though gold was discovered in this district in the early '60s, little was done until the discovery of the Gold Road by a Mexican prospector in 1902. This mine is now 800 ft. deep, with about 5000 ft. of drifts, and is equipped with a modernized ancient cyanide plant

Mohave County Mining Districts.
(After F. C. Schrader, U. S. Geol. Survey.)

of rather clumsy appearance but of high efficiency, a description of which appeared in the *Mining and Scientific Press* of November 12, 1910. This mine is under option to the United States Smelting, Refining & Mining Co., which has a corps of engineers engaged in sampling.

The Tom Reed mine is situated about a mile and a half southeast of the Gold Road, on a nearly parallel vein in andesite, the filling of which is andesite-breccia and fine-grained quartz, mingled with adularia. The shaft is 450 ft. deep, and, though the upper workings in the vicinity of the shaft are said to have been lean, more recent developments have disclosed bodies of ore 20 ft. in width, of excellent grade. At the time of my visit, the value of the ore going to the mill was about $50 per ton, the recovery said to be 97 to 98%. The ore was formerly treated by amalgamation alone, but early last year a thoroughly modern cyanide plant was erected, using the 10 stamps of the old mill as the first unit, foundations being put in, however, for 20 additional stamps. The stamps weigh 1050 lb., and the duty is about five tons of ore per stamp per 24 hours. In December, 10 more stamps were placed in commission, handling the tailing from the old mill. The ore is broken at the shaft by an Austin gyratory crusher, and falls upon a belt-conveyor which delivers it to a distributing-belt above the battery bins, about 100 ft. distant. Suspended feeders, of the Challenge type, feed the stamps, and 12-mesh screens are used, the pulp passing over amalgamating-plates into a Callow pulp settler, from which the sand is delivered to a 5 by 22-ft. tube-mill with spiral feed, driven by a 70-hp. motor; the overflow from the settlers joining the discharge from the tube-mill and passing over another set of amalgamating-plates and blankets. The small amount of rich concentrate which is caught upon the blankets is reground in a 3-ft. pan and the gold amalgamated.

The tailing from the blankets is pumped to a 3-ft. Callow settler, from which the slime passes by gravity to a 10-ft. settling-cone, the sand being returned to the tube-mill. The overflow from the large cone goes to two 10-in. cones, and the underflow to an Oliver filter, for de-watering; after which, with the pulp from the smaller cones, it is mixed with the solution, of 0.10% KCN, in a cone mixer, and delivered to a steel tank 20 ft. in diameter by 6 ft. high, whence it is pumped as required to the top of the Pachuca agitators. The Oliver filter was installed as a slime-filter, but when, after a few weeks use, holes appeared in the filtering medium where it bears on the frame, the management found it expedient to use the machine for de-watering, rather than to unwrap the thousand and one miles of wire which hold the filtering medium in place, replace it, and perform the rather delicate task of re-winding the wire. This is one of the weak points of the Oliver, and when the makers adopt some other means of holding the filtering medium, the machine will be more popular. The Portland mill, in the Cripple Creek district, has machines of this type, which seem to be giving entire satisfaction.

To return to the Tom Reed. There are three Pachuca agitators, 10 ft. in diameter by 38 high, and one tank is filled and one discharged each day. The charge is agitated 24 hours with air under 20 to 25 lb. pressure. The content is then discharged into a steel tank 20 ft. in diameter by 5 in height, equipped with stirring-gear, from which it flows to a Butters filter, of 48 leaves. The dissolved gold is precipitated on zinc-shavings and the precipitate melted, with a little flux, in a tilting-furnace using oil fuel.

At the Ruth mine, about five miles west of Gold Road, a 10-stamp cyanide mill is being installed which is expected to be in operation in March. The workings are not extensive, the shaft being but 150 ft. deep, but the ore exposed is of such grade that the revenue from the mill is expected to more than pay for development of the mine.

Near Union Pass, about 10 miles northwest of Gold Road, another cyanide plant is being completed

by the Gold Crown M. Co., in which no old-fashioned machinery has found a place, and its results will be watched with interest by local mining men. The Hardinge system of 'step reduction' is being installed, following a McCully crusher, with Merrill presses for both filtration and precipitation. The orebody at this mine is red andesite, occurring near the top of a low butte which has been formed by the erosion of the surrounding country. Locally the andesite is brecciated and highly silicified. It is 20 to 30 ft. in thickness, and dips about 15° northeast, lying upon a gray rhyolite and being capped by comparatively soft white rhyolite. The gold-bearing andesite shades into the rhyolite above and below, with no sharp line of contact. The andesite is said to carry more than ½ oz. of free gold per ton, in which case it will no doubt return a satisfactory profit. The cost of mining this orebody will be small, the ore being quarried out and dropped through chutes to the tunnel, through which it is trammed to the mill. Abundant good water is piped from a canyon three miles away, and conditions are favorable for cheap operation.

Across the Sacramento valley, to the north and east of the River range, a totally different formation obtains, and the character of the ores differs as greatly as that of the country-rock. In the River range, as stated above, the younger volcanic rocks—chiefly andesite and rhyolite—prevail; while, across the valley the rock is a pre-Cambrian crystalline complex, consisting mainly of gneisses, schists, and gneissoid granite. The ores, while usually carrying gold and silver in appreciable quantities, are base, being essentially lead-zinc ores, with considerable iron and some manganese and other metals. Locally the orebodies contain much gold and silver, especially the latter; and practically all the known orebodies were worked in the early days of the district, the rich surface ore having been gouged out by 'chloriders', leaving the leaner oxidized ore and practically all the sulphide ore below the water-level, which is usually only 75 to 100 ft. below the surface. The country is broken owing to intrusions of granite-porphyry and dikes of rhyolite and diabasic rocks. Consequently, erosion has created a rugged topography, though many of the mines are situated at or near the base of the mountains, and some of them within the valley. Present activity in this region is due principally to treatment facilities now afforded by the Needles smelter for this class of ore, and the reduction in freight and smelting charges. The U. S. S. R. & M. Co. has also promoted the welfare of the district by taking an active part in mining operations. For more than a year this company has been engaged in exploiting the field, but is now confining its efforts to re-opening the Tennessee, a former large producer, situated about a mile from the town of Chloride and 25 miles from Kingman. This mine had a big mill in operation a few years ago and shipped a large amount of high-grade ore, being worked to a depth of 600 ft., when operations were discontinued, presumably because of the volume of water to be handled. The old shaft has caved in and a new one is being sunk to a depth of 700 feet.

Numerous other lead-zinc properties in the vicinity of Chloride are being worked on a small scale, and there are some very good showings at shallow depths. Occasional shipments are being made which bring very good returns. The Juno mine, which is situated in the low foothills close to the town of Chloride, is being cleaned out by Los Angeles men who have a long-term lease on the property. This mine was developed in the early days to a depth of 600 ft., and made a large production. It has three old shafts and a steam-hoist, and the vein, which is 4 to 12 ft. in width, is exposed for more than a mile. The dumps and the oxidized ore in the old stopes of the Juno are said to average between $7 and $8 per ton in gold and silver, sufficient to yield a good profit by cyanidation; and it is the intention of the operators to erect a small mill to treat this ore and the tailing from the lixiviation plant which treated the higher-grade silver ore in the palmy days of the mine.

The Champion mine, just over the range from Cerbat, is making a steady and apparently profitable output of base ore; and the Golconda, conspicuously situated high on the western slope of the mountains two miles northwest of Cerbat, employs 75 men; and the many new buildings and score or more of housetents which perch on the mountain side, below the shaft and the mill, denote activity and prosperity which are in quite pleasing contrast to the general dullness prevailing in other parts of the base-metal region. The Golconda was opened by the present operators about three years ago, and has shipped about 18,000 tons of ore carrying as high as 50% zinc, with considerable gold and silver. A mill has recently been erected, consisting of a trommel, two sets of Harz jigs, and two Wilfley tables, for the purpose of handling the fine material in the dumps. Two reciprocating surface tramways deliver the ore and concentrate to bins at the foot of the hill, where wagons have easy access.

On the whole, the mining industry in Mohave county is on a decidedly substantial basis. Copper, molybdenum, and other metals and minerals besides those mentioned, occur in quantities which will render them commercially valuable not very far in the future. Along the River range, northwest of Chloride, are profitable gold mines which have not been mentioned, and interesting developments are in progress. North of the Colorado river and remote from transportation facilities lies nearly one-half of the county—an immense undeveloped territory rich in minerals and containing large tracts of fine timber, much of which, in due course of time, must find its way to the market.

California petroleum stocks, January 31, amounted to 27,460,000 bbl., an increase of 450,000 for the month, according to the *Oil World*. Consumption, exclusive of oil burned in the field, was 5,292,325 bbl. for the month, a daily average of 170,720 bbl. The production amounted to 197,155 bbl. per day.

Superstition in Mining

By T. Lane Carter

Mining men who have studied the early volumes of the *Transactions* of the American Institute of Mining Engineers, have read the fascinating paper by Dr. R. W. Raymond* on the 'Divining-Rod.' In it he traces the influence this superstition has had on the human race for centuries past. In ancient times much dependence was put on the divining-rod. Mining can not lay claim to the first use of this instrument. In olden time it had a moral use and was in evidence whenever guilt was to be discovered or predictions of future events were to be made. There was a mixture of demonology in the belief in the divining-rod, especially in the Middle Ages. Before the rod was used there were many incantations, and frequently the rod was baptized by a bishop, being laid for this purpose in the bed with a newly-baptized child. Those of us who have had much experience with the uncivilized natives of Africa, realize that the superstition of earlier times remains among them, in the 'smelling out' by the 'witch doctors' and the use of twigs and branches for divination.

The divining-rod has played an important part in the history of engineering. Claimants by the thousand have announced to the world their power of finding water or ores by the use of this instrument. A few hundred years ago the possessor of such a secret had to be careful how he announced his accomplishment, for if he were not cautious, there was a chance of being accused of sorcery by the rabble and being burnt at the stake as a co-worker with the Evil One. But all that danger is past now, and the large numbers of believers in the divining-rod scattered over the world are no longer considered suspicious characters. Along with each science there grew up a pseudo-science. Astronomy had astrology; chemistry, alchemy; and mining, the divining-rod. The contributions of astrology were not all negative, and alchemy did a great service for chemistry. Along with the jargon of the users of the divining-rod we read some astute remarks about rocks and springs. The use of this instrument was common in Cornwall and Germany. In the United States the divining-rod has been extolled by engineers. Dr. Raymond mentions the case of a gold mining company in California that employed one of these diviners to point out where a lost vein was to be found. After many incantations, the gentleman showed the management where to look for the vein. They set to work in good faith in the firm belief that the vein would be found, but after spending thousands of dollars they came to the conclusion that the diviner must have had an 'off day' and that his rod was not working when he located the vein.

My experience with the divining-rod has been limited, but I have seen enough to know that the belief in its efficacy has not passed away. At a mine in Africa a few years ago, we were short of water, and I decided to sink a well. The engineer came in one morning and asked if I had decided on the location. I told him I had not. Then he mentioned that a water-diviner, a long-bearded Boer patriarch, had arrived on the property with his Y-stick and would find water for us, provided we gave him £2. If we sank a well at the place he pointed out and did not find water, he would not ask for any money. I told them to go ahead. In a half-hour the engineer ran up, greatly excited, stating that they had found water. I asked if they had already sunk the well. He said the Y-stick was behaving in the most extraordinary manner, and asked me to come and see for myself. I walked over the place with the stick held out in front of me, one end of the Y in each hand, but my faith was small and the thing did not budge. When the engineer walked over the point selected by the Boer the branch twisted and turned as if a rope were pulling it. It was a case of minute unconscious muscular movements, caused by the imagination of the operator. The old Boer had mesmerized him, I think. We sank the well and got a fine flow of water, and the patriarch got his £2. Months later I found that this part of the property had been disturbed by a fault. I put down this lucky find of water to shrewd geological observations on the part of the Boer rather than to any power of the divining-rod.

The next place I ran across the instrument was in Chicago. A well dressed young man came in one day and stated that he wanted to see the operator of the divining-rod. His mother had told him to see such a man the next time he went to the city. It appears that the old lady had had two sittings with a clairvoyant and that on both occasions the medium had told her the same story about a Spaniard of the adventuresome days of 1720 burying a chest of gold at some place on her farm. The young man asked what the charge would be to take the divining-rod and find the treasure. I told him I thought he had gotten into the wrong pew, and that he would save money by making the business proposition to the clairvoyant of giving her half the treasure if she would point out the exact spot where the gold lay.

There is something about mines that appeals to the superstitions of mankind. In ancient times the life of the miner was the lowest and hardest of all. The Romans sacrificed thousands of slaves every year in digging for mineral wealth all over the empire. On account of the lack of ventilation, and the CO_2 and CO given off by the burning wicks and wood, the life of the miner was short. No wonder that among freedmen the mining regions were held in terror, and that none save slaves would work underground. With such a high death rate it is natural that superstition spread among the people, and that they pictured the mines as the abode of evil spirits. In the Middle Ages there are

*'The Divining-Rod', by R. W. Raymond; *Trans.* Am. Inst. Min. Eng., Vol. II, p. 411.

innumerable references to mines and the ghouls who were supposed to live in the shafts.

The Chinese are naturally superstitious, but I believe that mine work makes them more so. Whenever there was an accident in the mine and one or two of the Celestials were killed, they would frequently shoot off firecrackers near the place of the accident, and burn candles to propitiate the spirits of the departed. I have had Chinese who would not work underground on account of their strong superstitions. The Kaffirs are far more phlegmatic than the Chinese, and yet they have their mining superstitions. It is almost impossible to get a Kaffir to work in a quiet part of the mine entirely alone. I have seen it tried several times, but the native would stay a few hours and then run out, saying he had "seen things" in the darkness. It is customary to have two or more Kaffirs at work together. I must myself confess to one mine superstition, and that is that when you have one fatal accident in a mine you will have three. In my observations mining accidents come in cycles. The work goes along for months at a time without an accident. Then some one gets seriously hurt or killed, and troubles come fast for a while.

One of the strongest superstitions I have noticed in men who have spent most of their life in mining, is a sense of danger that suddenly comes over them. Some would call this faculty the 'sixth sense.' If you asked the miner how he knows there is something wrong, he will reply that he "feels" it. I had a remarkable illustration of this a few years ago. I was walking along a main drift with a mine captain, a man who had been working in mines for over forty years, having started as a lad in the mines of Cornwall. Suddenly he stopped and exclaimed that something was wrong. For the life of me I could not see a thing amiss. The timbers seemed solid, and the drive pillars looked secure. But the captain was not satisfied, and insisted on climbing into the stope to investigate. There he found a large crack, running for hundreds of feet, indicating a movement of the strata of serious proportions. Had this discovery not been made in time there would have been a serious accident in the mine with a probable loss of life. I dare say the years of experience in the mine had developed a power in him which the men called 'superstition,' but was really the faculty of accurate observation, which to him seemed unconscious.

One constantly sees instances of superstition in the mining districts of Mexico and the other Spanish-American republics. It is probable that the many shrines of the Virgin one finds in the underground workings are monuments to superstition rather than religion. If you watch the peons pass by a place in the mine where a miner has been killed, you will see that they cross themselves furtively and hurry along. Volumes could be written about the legends and superstitions of the old mines or *antiguas* that abound in Mexico. About seventy-five years ago a sad fatality happened at one of these old mines. Rich ore had been struck and the Mexicans were straining every nerve to get out the valuable stuff. The workings were down nearly 300 feet and the high-grade ore was carried to the surface by peons. It was 12 o'clock, and the boss of the laborers told his young son to fetch some water from a spring at the bottom of the mountain. When the lad returned he found that the mine had caved in, burying every man. Rushing to the village he summoned all the people, but they were never able to rescue the bodies, and the *padre* said prayers over the dead, and left them there to this day. Needless to say, around that mine there are many tales and superstitions. The peons say that the spirits come out once a year and travel around the mountains. If one tells you the story at midnight and a branch of a tree rubs against the roof of the shanty, the Mexican will say, "There goes one of the spirits now"!

One of the oldest superstitions connected with mining and metallurgy is the dream of the transmutation of metals; the turning of the base metals, such as lead, into gold. Until chemistry became established, this dream was universal. It has by no means vanished. Ever since the discovery of radium some people have declared that the secret of making gold would soon be found. They declare that radium has completely disturbed the established views regarding the ultimate constitution of matter. To my knowledge no great physicist has yet claimed that radium has upset our hypotheses, nor has any chemist of note yet promised us that ere long we would be turning out gold from lead. It remained for an electrician, Thomas A. Edison, to tell us in a recent sensational article that before long gold would be dethroned, and would be made cheap in two ways. First, by finding out how to make it from some other substance, and secondly, by mining the clay which occurs in millions of tons under one of our Eastern cities, and which assays 30 to 40c. per ton. After reading this lurid article all I can say is that mining is not the only line where one finds superstition, but that electricians also suffer from this weakness.

Official records of mineral exports from Western Australia commence in 1850, when a small quantity of lead ore was exported from the Northampton mineral field, and three years later a small amount of copper ore is found among the exports. Ores of these metals continued to be the principal mineral production for many years, copper mining at Northampton reaching its zenith in 1864 and lead mining in 1877. Exports of gold are first recorded from Kimberley in 1886, followed by Pilbara and Yilgarn in 1889; Ashburton and Murchison in 1891; Dundas in 1893; Coolgardie in 1894; North Coolgardie, Northeast Coolgardie, and East Coolgardie in 1896; Peak Hill, Yalgoo, East Murchison, Mount Margaret, and Broad Arrow in 1897; Gascoyne and Donnybrook in 1899; and Phillips River in 1902. Exports of tin ore from the Greenbushes mineral field first appear in 1889, and from Pilbara in 1893. Coal is shown for the first time in 1898; mica in 1892.

Amalgamation in Slow-Speed Chilean Mills

By E. E. Carter

With a view to increasing the capacity and also the amalgamating efficiency of the Gold Hill mill, of the Gold Hill & Iowa Mines Co., operating near Quartzburg, Idaho, careful tests have recently been made along the lines suggested below. The changes made as a result of these tests have enabled the elimination of concentration and cyanidation; the whole treatment being now by simple amalgamation.

The ore is a comparatively soft quartz, carrying less than 5% sulphides, iron pyrite being the most important, lead and antimony sulphides constituting a very small percentage. Gold is the chief source of value, and this is found to be closely associated with the antimony. Very little shows in the pan without first briskly rubbing it. Crushing is done through a 9 by 15 in. Blake crusher which crushes to approximately 1½-in. ring. The ore then goes to 1000-lb. stamps, having a rapid drop, but falling not over 5 in. The discharge is set even with the die and ¼-in. screens are used. No amalgamation is attempted within the battery, the sole object being to get capacity.

At first an attempt was made to run the pulp from the stamps into a cone classifier, allowing the overflow to pass directly over the plates and the underflow to go into the roller mill to be recrushed. This scheme was abandoned, as the gold passed over the plates with the slime from the overflow. The entire pulp was then fed into the roller mill and surprising results followed. Special attention has been given this Chilean mill, and in order that it may be understood by those not already familiar with it I will briefly describe it.

The mill is known as the Lane slow-speed Chilean mill. It is 10 ft. diam. and has six wheels instead of three, as have most Chilean mills. In order to provide for the excessive weight required, the wheels are not made solid, but are weighted by means of a large tank filled with scrap-iron or rock. This is also a consideration in transportation. This tank is directly over all the wheels and is loaded with at least 12,000 lb., which, together with the wheels, gives a crushing weight of about 25,000 lb. The mill runs very slowly, not over 8 revolutions per minute. This allows the resultant of weight to act downward instead of outward, as in high-speed mills. It has also an important influence on repairs. The wheels are set at a slight tangent, which gives a dragging or grinding action similar to that of the old and efficient arrastre. The outside copings or sides are set at a slight angle (possibly 60°). As the pulp flows around this side the centrifugal force tends to throw particles upward as well as outward. The whole action is one of classification. This action tends to allow any mercury that is inclined to flour to settle, while the heavy particles accumulate and are crushed by the passing wheels. As the circumference of the pan is somewhat over 30 ft. it gives an excellent opportunity for the mercury to unite with the particles carrying gold which has been brightened by abrasion. Once amalgam is formed it settles down around the dies and has very little opportunity to escape.

The mill is driven by a large gear which entirely surrounds the mill, and which in turn is driven by a pinion and bevel gear similar to those employed in the construction of a winch. Ammeter tests have shown that about 5 hp. is required to run the mill while crushing, but the builders claim that 12 is required. Experiments were made in feeding a 6-mesh product, but it was found that the capacity was not increased proportionately, as the particles simply followed the wheels. The discharge of the roller mill was set so that with a 10-mesh screen a 30-mesh product was obtained. It has since been found advantageous to do away with the screen entirely and depend upon an overflow discharge. With this discharge arranged so that it is slightly higher at the end toward the approaching wheels a very even flow can be maintained. Screen tests with the discharge set at 6 in. show that 80% will pass 100 mesh and 90% will pass 80 mesh, while over one-half will pass 200 mesh.

A great advantage which the overflow discharge offers in treatment of this ore, is that in working ore from old filling the chips and fuse pass the mill unobstructed, or are easily removed. The cost of screens is also an item in its favor. A slight wave is made ahead of each wheel and a corresponding depression behind it. Into this is fed the pulp from the stamps through six pipes, which are carried around with the wheels. Each particle is carried around many times and it is constantly being dragged over the mercury or amalgam formed around the outside of the die. The finer it gets the higher in suspension it is carried until it reaches a fineness which allows it to overflow. It has been found beneficial to obstruct the free flow of the pulp somewhat, and baffles have been fastened to the outer curbing, which tend to retard the rapid flow and allow the wheels to catch up. A narrow space is left around the outside of the die and in this most of the mercury and amalgam accumulate, as well as a rich concentrate.

Although a great excess of mercury is fed, very little is shown in the discharged product, and a careful account has shown that most of it is recovered in the clean-up. The last mill run where amalgamation in the mill averaged $7.10, did not show enough amalgam on the outside plates to warrant trying to remove it. Twenty stamps are in operation in the same mill and 50 to 55% has been as high an extraction as it has been found possible to make by amalgamation on plates, while on the same ore the Chilean mill has done better than 81%, and 85% is hoped for. On reaching this figure it will be possible to omit the cyanide treatment which has followed stamp-milling. The stamps crush through fine screens and it is found that the gold is not saved, screens are very expensive, the mercury flours badly, and the final product is not in as good a condition for subsequent treatment. The above suggestions are offered believing that this subject is worthy of further discussion.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Oliver Filters

The Editor:

Sir—In Philip Argall's article entitled 'Review of Cyanidation in 1910', published in the *Engineering & Mining Journal*, January 7, 1911, he states: "The drum form of continuous filter, of which we may take the Oliver as a type, appears to be coming into use in the United States and Mexico; they all leave much to be desired; the complication of automatic valves on vacuum, pressure air, and wash-water prove troublesome." I do not intend to discuss here the relative merits and demerits of various types of filters, but wish to take exception to statements by an engineer of such high standing as Mr. Argall that are evidently based, not on the observation of the operation of an Oliver filter, which has never had "valve troubles", but upon the difficulties experienced by a rank imitation of the Oliver filter which has lately been built in Denver and which filter has necessarily had to omit the vital features incorporated in the Oliver. While I do not object to having the Oliver referred to as a type, I do most strenuously object to having the filter blamed for the deficiencies of inferior imitations. In substantiation of the fact that the Oliver does not have "valve troubles", I beg to state that in the four years that I have been building these filters, no changes have been made in mechanical principle or general design of the valve.

EDWIN LETTS OLIVER.

Thin Rock-Sections

The Editor:

Sir—Replying to 'Inquirer' in your issue of February 4, I take pleasure in offering the following suggestions for making thin rock-sections. Apparatus required: An ordinary jewelers' polishing lathe to be worked by treadle may be used, but if any considerable amount of work is to be done, it will pay to purchase a properly equipped cutting and grinding machine. G. D. Julien, Bloomfield street, Hoboken, New Jersey, makes these machines complete, and they cost from $100 to $300, according to whether they are for foot-power or equipped with an electric motor. If an ordinary polishing lathe is to be used, these mounted on a stand, operated by a foot-tread, cost about $12. A diamond-edged saw of about 8 in. diam., sold by Elisha T. Jenks, Middlesboro, Massachusetts, is almost indispensable, and must be ordered with the centre hole of the right size to fit the mandrel of the lathe. These cost about $1 per inch of diameter. I use in addition several carborundum discs of the same diameter, having for general use one each of No. 60, No. 120, and No. 220. For final polishing and grinding I find that copper discs, made with slightly convex surface, have about the right degree of hardness to hold flour carborundum, or rouge, as the case may be. It is well to have at least two of these, one for the medium or preliminary polishing, and the other for polishing. Several pieces of plate-glass about 2½ in. square, two ounces Canada balsam, mounting slides, cover glasses, various grades of carborundum, from F to the finest hand washed, besides some infusorial earth and jewelers' rouge for final polishing.

The modus operandi is as follows: Select a typical portion of the specimen, as free from fracture as possible, and with the saw in place hold a piece of rock gently against the saw edge, being sure to keep a small but steady drip of water to lubricate the cutting edge. If the saw has been carefully adjusted this first cut will leave two pieces of rock with comparatively plane surfaces, which will need but little further grinding and polishing to become absolutely flat surfaced. When the sawed surface has been polished and is quite free from scratches, which must be proved by inspection with a low-power lens, it is ready for the next step. This polished surface is then cemented with Canada balsam to one of the plate-glass squares, and when set, another cut is made with the diamond saw, leaving a fairly thin section on the plate-glass. This is then ground down on the carborundum discs, with constant inspection, and extreme caution toward the final reduction in thickness; the section is reduced to a finely plane polished surface, and when thin enough so that all the darker minerals are transparent, and all scratches have been removed, the section is ready for transfer to its permanent slide. Before doing this it should be carefully washed with water, then with a little spirits of turpentine, or alcohol, using a camels-hair brush or piece of clean linen rag. The glass slide is then heated on a hot plate, and a drop of balsam placed thereon, and heated so as to drive off any bubbles; at the same time the plate-glass on which the grinding has been done is also heated so as to make the removal of the section easy, then, with a long needle mounted in a handle the section is gently removed from the one to the other, Canada balsam placed on top of the section, and a cover glass put over it, and pressure applied so as to exclude all bubbles, and leave a uniform film of the balsam on the surfaces of the section. I find that a good way to hold the cover glass and section in place while the balsam is setting is by means of a stiff spring clip, with cork mounted on the ends.

I would recommend 'Inquirer' to get Luquer's 'Minerals in Rock Sections,' Rutley's 'The Study of Rocks,' or 'Rock Minerals,' by Joseph P. Iddings. On delicate, and in fact on almost all sections I find it safest to do the final finishing of the polish by hand, using a piece of plate-glass with a little thin oil and rouge. This is better than attempting to put the finishing touches with a rapidly revolving disc, which frequently causes the loss of the entire thin section, when the bulk of the labor is at an end. For a large amount of work I recommend a motor-driven machine, and the cutting and grinding outfit especially

made for this purpose, as recommended at the commencement of this article. Anyone mechanically inclined can make the necessary guides and carriers for the rock, both for the cutting and later the polishing operations. I believe with the above description, which is merely an outline, 'Inquirer' can get the desired results without much difficulty.

H. Vincent Wallace.

El Paso, Texas, February 9.

The Editor:

Sir—Replying to 'Inquirer,' in your issue of February 4, I may mention that Bulletin 150 of the U. S. Geological Survey gives good suggestions on the preparation of microscopic sections of rocks, as does J. P. Iddings in his book entitled 'Rock Minerals.' I have, while away from the usual apparatus, made sections by grinding down a chunk of rock on an emery wheel in a machine shop until it was too thin to hold and then finishing it off in emery sand with sweet oil, using finer sands as the section becomes thinner.

LeRoy A. Palmer.

Salt Lake, Utah, February 12.

Protection of Investors

The Editor:

Sir—Notwithstanding all of the discussion in recent periodicals regarding the protecting of the public from investing in 'wild cat' concerns, both mining and industrial, I have not seen a definite plan of action proposed that would effect a solution of the problem. The Government has been active lately in closing a number of the 'get rich quick' concerns, but in each and every case the damage had already been done and millions of dollars extracted from the gullible public, that can never be returned. It seems to me that what we want is prevention.

Although the vendors of bogus stocks do not confine their operations to the mining industry alone, it is that we have to deal with, and an obligation rests on the legitimate operators, mining engineers, and honest mining men in general to devise some means whereby the public can be protected in a large measure when dealing in mines and mining stocks. The large operator or investor needs no protection; he can look out for himself. Of course I recognize the fact that no scheme could be advanced that would guarantee absolute protection, for as long as the idea of getting something for nothing prevails in a majority of the human race there will always be 'suckers' for every scheme advanced.

At the present time a number of the States have laws designed to protect the investor after his money is up, but none of them is very effective. I believe that the whole matter could be handled by the new Bureau of Mines in a way that would be much more satisfactory. Establish a general bureau of information in Washington and divide the country into districts with a competent inspector in charge of each district. When the incorporation papers of a new mining company are filed, make it compulsory for the incorporators to file a statement with the district inspector giving the names of the officers of the company, amount and location of the ground, capitalization, amount of promotion and treasury stock, and other facts pertinent. Make it compulsory that time enough elapse after the filing of this document to allow the inspector to substantiate the statements made and file his report in Washington. If the whole scheme is an obvious swindle, publicity can immediately be given in the papers by the Bureau. If the intentions of the company are honest the report is on file, and those contemplating investment can secure the facts by writing the Bureau. The inspector of the district can follow up his first report by supplementary reports so that if anything crooked develops later, action can be taken at once. If the public can be assured that the officials of the company are reputable men, that the company has the ground claimed, that it is in mineral-bearing territory, that their money will be spent in legitimate mining operations, and that the statements in the prospectus are not gross exaggerations, I believe that investors would be protected as well as can be done. There is no doubt that such a course of action would be of great benefit to the whole mining industry and save millions of dollars now squandered on bogus concerns.

In connection with this I also believe that it would be of great benefit if the U. S. Geological Survey had several men on skirmish duty, as it were. Whenever a new camp or district is discovered and has advanced so that it shows promise, let one of these geologists make a preliminary survey of the district at once and publish his report immediately. It would be of incalculable value in planning development in the district. In advancing this idea I have special reference at the present time to the National mining district in Nevada. Here is a district at least two years old that has produced over $1,500,000 and has not as yet been visited, so far as I know, by any member of the Survey. A preliminary survey here might have saved many thousands of dollars spent in useless work, and the same is true of many other camps.

Reno, Nevada, January 9. H. C. Cutler.

The Cape to Cairo railway continues to progress, nearly 1500 miles having been completed from Cairo southward, and nearly 2500 miles from Cape Town northward. The terminus of the northern section, lately at Senaar, 160 miles southeast of Khartoum, is now at El Obeid, the capital of Kordofan. The end of the southern section, lately at Broken Hill, is now at the frontier of independent Congo, 400 miles north of Broken Hill. The wealth of the 30,000,000 Congo State natives influenced the managers to change their original plan and steer straight for that territory. The railway line which runs from the mouth of the Congo river, on the Atlantic coast, to Stanley Pool, and which will soon be extended eastward, was another attraction. From the Congo frontier at Kassanshi the line will be continued 120 miles northward to Katanga by the French Katanga railway. Again, from Kassanshi the Cape to Cairo main line will run northwestwardly another 400 miles to Lake Tanganyika.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Osmium is used to a small extent in some kinds of incandescent lamps. It is quoted at $33.70 per troy ounce.

Palladium, which is well adapted for parts of astronomical instruments and certain dental work, sells at $34 per ounce.

Rhodium, which is of considerable value in making high temperature determinations, is quoted, when pure, at $155 per ounce.

Potash salts come principally from an enormous deposit at Stassfurt, Germany, which, at the present rate of exploitation, will last, it has been estimated, about 600,000 years.

Fuller's earth has been largely used for cleaning grease from cloth and furs, but it is now chiefly used in this country for clarifying oils. A recent report by the U. S. Geological Survey discusses the chemical composition of the material and presents theories to account for its peculiar properties.

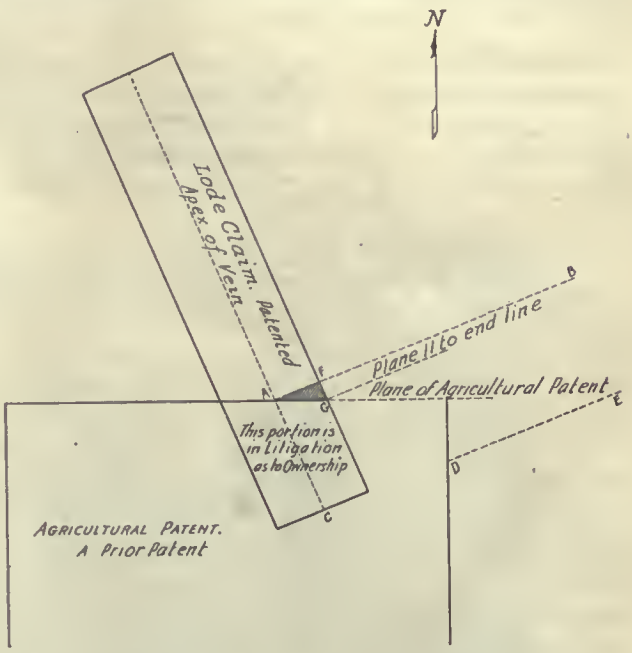
Iridium is used principally for hardening platinum alloys. In 1909, according to the U. S. Geological Survey, the imports of iridium amounted to 341 lb., valued at $135,878, the average cost being about $33 per troy ounce. The cost is rapidly advancing and was quoted at $60 per troy ounce in October 1910.

Rock salt deposits in Michigan are of interest in connection with the current discussion of possible sources of potash. The red beds of the southwestern United States contain deposits of gypsum and rock salt and may be possible sources of potash salts. These beds might profitably be explored in places where conditions favor the accumulation of such salts.

Hornblende rocks alter in different directions, according to the condition of metamorphism. The same rock might well give rise to a mica schist and to something roughly classified as slate. Under weathering conditions hornblende ordinarily changes to chlorite, which is often accompanied by epidote, calcite, quartz, iron oxides, and siderite. Under deep-seated conditions biotite is frequently formed from hornblende. Occasionally epidote forms at the same time.

Gouge is finely ground rock found along vein walls. It is a product of pressure during faulting, modified often by the later action of circulating water. It is not always equally developed on both walls. If in a given case the hanging wall be thought of as remaining fixed and the foot-wall as rising along it, the foot may be conceived as raveling off against the hanging, and the natural result would be a well developed gouge along the hanging, one that was sporadic only along the foot, and a vein filling which may include at any given level, fragments of any of the rocks in that part of the foot-wall that has been raised to or above the level chosen.

Where the lines of a lode location are laid out so as to extend over on prior patented agricultural land, a serious question arises as to whether the lode claimant is entitled to an extralateral right for that segment of the apex of the vein which is included in the agricultural land. There are no authorities, so far as we are aware, deciding this question, as far as agricultural conflicts are concerned. In the case of conflicting lode claims, one line of cases holds that the junior locator is entitled for the full length of the claim after eliminating the extralateral right of the senior claim. Another line of cases holds that the junior locator is only entitled



to an extralateral right based on the segment of apex that exists within 'free ground' (that is, within surface area of his claim to which he is entitled). Applying the first rule to the case below, the extralateral right of the lode claimant would be bounded in a southerly direction by the vertical plane C D E passed through the southerly end line but eliminating all that portion of the vein lying beneath the surface of the agricultural grant. The second line of cases would be authority for limiting the extralateral right in a southerly direction by a vertical plane A B passed through the point where the apex of the vein leaves the free ground of the location and parallel to the end lines. Of course the lode locator would be entitled to the segment of the vein lying vertically beneath the surface triangle A F G by virtue of his ownership of the surface. The Land Department a few years ago intimated that no lode location might have a 'theoretical apex' along the boundary of the agricultural grant, but this doctrine has not been received with much favor. Until the United States Supreme Court has passed on this extralateral right matter, it will be involved in doubt. Whatever principle is applicable to agricultural conflict would seem to apply to conflicts of lode locations with millsites or placers. 'Known lodes' in placers would, of course, be an exception.

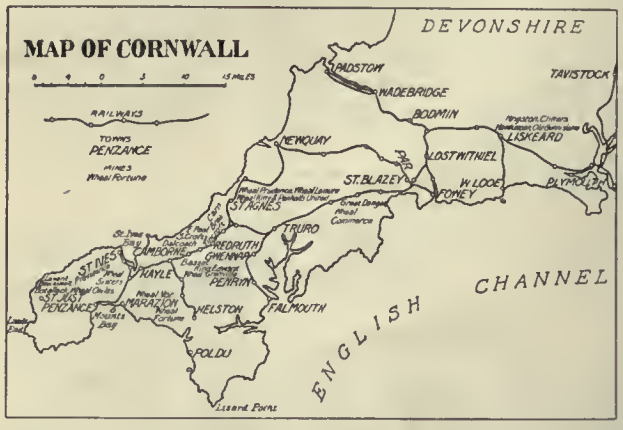
LONDON

J. H. Collins Reports on Cornwall Tin Mines. — Favors Continuing Operations.—Pitchblende at St. Ives.—Derbyshire Lead Mines.—Demand for Fluorspar.

There was never so optimistic a mining engineer as J. H. Collins, nor so devoted a believer in the resources of Cornwall. Mr. Collins is not a young man; many of us are contemporaries of his sons. But in spite of his years, his spirit is as buoyant as ever. Probably no one has so great a knowledge of the tin lodes of Cornwall as he; he knows all sorts of details of long-closed mines, and is doing fine service in recording his recollections and in perpetuating in published form the information he has relating to old properties.

Mr. Collins has just contributed a paper to the Records of the West Country Chamber of Mines, that should en-



courage others in this or in future generations to try their hands at winning some of the tin that is still there. He begins by saying that the drop in the production of tin during the last 15 years has not been due so much to the decrease in the production of mines continuing in operation as to the abandonment of mining in many districts that used to be of importance. The production is now centred round Carn Brea hill, and the only other regular producers that have much to sell are found in the St. Just and St. Agnes districts. The Calstock district in East Cornwall promised a few years ago to show a revival, but the mines on which so much energy and money were spent, Hingston and Clitters, have once more been closed. With the above exceptions, it has to be admitted that all the districts once famous as producers have been practically abandoned. It is true that mining operations are being continued at St. Ives, Wendron, Chacewater, and Liskeard by isolated companies, but these districts generally, as well as those of Breage, Gwennap, Perran, St. Austell, Callington, and Tavistock are now quite neglected. Mr. Collins sees no scientific reason to account for this widespread abandonment, and considers that with capital and perseverance they should once more become important producers of tin. He does not advocate the re-opening of old, deep mines full of water, but there are many districts where shallow levels contain ore that would pay nowadays without much sinking and pumping. For instance, at Wheal Kitty, at St. Agnes, many hundreds of tons of tin concentrate have been raised during the last four years from ground between the 300 and 500-ft. levels, in spite of the fact that the mine has been worked continuously for over 100 years. Mr. Collins describes the several districts in the west of Cornwall and commences with St. Just near Land's End. This was once and may be again one of the great producers. Levant and Botallack have been working for over a century, and though the present position is unfavorable, there is no good reason why operations should not be profitable. The St. Just district is a strip of country on the coast line consisting of greenstone and metamorphosed slate (locally, 'killas'), averaging ⅛ mile wide and 4½ miles long. He considers that it is probably unsurpassed in mineralogical and geological interest by any region of equal size in any part of the world. At least 50 lodes are known and many are visible on the cliffs.

In the St. Ives district there are two separate groups of mines. One stretches along the valley southwest from the town of St. Ives toward Towednack, and is contained in a belt 2 miles long and ½ mile wide. The other is farther to the south between Trink and Trencrom Hills extending to the east toward Carbis Bay, the whole area measuring 4 by 2 miles. The average character of the lodes in this district is much the same as that of the lodes in St. Just district. The presence of pitchblende makes the similarity especially notable. The St. Ives Consols is the most important mine in the district and was started in 1816. It yielded much tin and copper, and was notable for beautiful crystals of chalcocite and for rich specimens of pitchblende. During the last two years much money has been spent in re-opening this mine, and in the Giew section, toward the northwest, profitable orebodies appear to have been found. Wheal Trenwith adjoins St. Ives Consols, and its dumps have recently become of interest owing to the large amount of pitchblende found in them.

The Providence group of mines is at the east end of the southern St. Ives district and is close to Carbis Bay. These mines were worked from 1832, and yielded much copper and tin; pitchblende is also found here. During the last four years the Tasmanian Exploration Co. has re-opened some of them and has erected a 10-stamp mill. Unfortunately most of the money has been spent on surface equipment, and too little underground development has been done. As the mines were worked by the old owners to only a comparatively shallow level below adit, Mr. Collins feels confident that systematic underground exploration and development would be justified. Another district worth examination includes Breage, Marazion, and Newlyn. It is often included in one district with Hayle and Gwinear farther to the north and east, but the geological conditions are different, as the slate is softer and contains many greenstone intrusions. More copper has been raised than tin, which is believed to be due to the fact that the workings are shallow and have not gone down to the tin. He instances several old mines on the shores of Mount's Bay which had not been worked to any great depth, but which were troubled with water in the early days. Mr. Collins deserves the thanks of all mining men for these records founded on personal knowledge.

Lead has been worked in Derbyshire from time immemorial, but in modern times, the old laws still extant, the troubles with owners of river rights, and the cost of transport of ore to smelters have combined to restrict operations. There are several lead-mining companies making a fair production in Derbyshire, but as they are owned privately, no information is available as to their methods of mining and treatment. A new company called Derbyshire Minerals, Ltd., has been formed with a capital of £45,000, to acquire a number of properties in several parts of Derbyshire. The most interesting are the old mines in Smalldale and Pindale near Castleton. These are, no doubt, the mines referred to by Sir Walter Scott in 'Peveril of the Peak,' in which story he used the classical expression, "Now you drift drivers!", thus accentuating the difference between the words 'drift' and 'drive'. Other properties are farther to the east and south, including some on Longstone Edge and others at Eyam and Stony Middleton. As is well known, these Derbyshire lead mines contain large amounts of fluorspar which until recent years was a drug on the market. Owing to the great demand for fluorspar from steelmakers, who use it in the basic open-hearth furnace for the purpose of increasing fluidity, many of these lead mines in Derbyshire have been re-opened and the old dumps exploited. In fact, this industry has been most profitable during the last few years.

DENVER, COLORADO

Committee on Mines and Mining.—Cripple Creek Items.—Conditions in the San Juan District.—Gilpin County News.

The Denver Chamber of Commerce is to be congratulated on its selection of a committee on mines and mining for 1911. This committee is already at work in behalf of the metal-mining industry of the State. In conjunction with the Denver branch of the American Mining Congress, the Chamber of Commerce is strongly opposing the present House bill No. 306, which seeks to raise the general taxation on mining property throughout the State. The proposed increase in valuation is the modest sum of $39,000,000. What logic there is for such an increase is hard to see when one considers the steadily declining metal production of Colorado. The present system is certainly not just. It seems as if some equitable basis of taxation could be devised if a little common sense, instead of political expediency, were applied to the problem. The bill providing for the tunneling of the Continental Divide is still in doubt and probably will fail to pass, although all the Denver organizations and the local press have worked for it.

The production of the Cripple Creek district for February was 70,170 tons of ore, of a gross value of $1,273,570. The Blue Flag, Anaconda, and Wild Horse mills are in operation, and this circumstance runs up the tonnage and decreases the average value. The Elkton and Golden Cycle companies have announced dividends of $37,500 and $30,000, respectively. Prospecting on the surface has received considerable attention recently, and four promising veins have been opened in different parts of the camp. The cross-cut from the Deep Drainage tunnel to the C. K. & N. vein has tapped little water as yet. Meanwhile, that in the deeper mines of the district continues to lower at a satisfactory rate. The tenth level of the Anchoria Leland, on Gold Hill, is dry, and filled with foul air. While prospecting these old workings on February 25, two miners were smothered. At the time of the explosion, which wrecked the upper Granite shaft-house, the Portland company was forced to protect its buildings from the resulting fire. This company has put in a bill to the insurance companies for the money spent at that time. The case is of interest, as it involves one of the fundamental principles of insurance and promises to be hotly contested.

The deep snows and frequent slides are bothering the operators in the San Juan district. The boosters at Telluride are hopeful that a smelter will be established in that town. The Newmire mine of the Primos Chemical Co. has resumed operating after two months of idleness. Several other prospects and small producers of vanadium ore on the San Miguel river are being worked in anticipation of the erection of a local treatment-plant when the season opens. The restraining order against the Valley View Consolidated Mining Co. of La Plata county has been refused by the Federal court. The Pay Day Gold Mining Co. alleged trespass and claimed that the defendant was removing ore of value from its property. The case was disposed of quickly when the defendant introduced a glass model showing the facts as they appear on the properties.

The Sadie A. mine, in the business district of Central City, is now in litigation. The claim originally belonged to the St. Louis No. 2 Co., which spent considerable money in developing the property, but, being rather unsuccessful, did not have the claim patented. A rich outcrop was discovered on the property last summer, and when the discoverer tried to get a lease on the property the faulty nature of the title was disclosed. The recent discoverers have bought a small plot on the outcrop and are sinking a shaft on the vein. The War Dance, and War Dance Extension claims, in the Russell district, have been sold to H. C. Eastman of Denver for $100,000. This is the largest deal in Gilpin county mining property for some time.

The 'Patch,' a Typical Bit of Gilpin County.

NEW YORK

Significance of Interstate Commerce Decision. — Outlook for Mining Markets. — New Mines Ready for Production.—Utah Copper. — Barnes-King.—Ray Central.

All the usual influences and factors in the making of market sentiment have become insignificant compared to the effect of the late decision of the Interstate Commerce Commission. It is considered to mark an epoch in the financing and in the financial management of railroad corporations; and is the portent of further regulation to come, for railway companies and corporations in general. The Standard Oil and Tobacco Trust cases now loom larger than they did a few weeks ago, while the practical certainty of a special session of Congress means a period of business stagnation. The opportunity to change tariff schedules cannot be overlooked by busy politicians, and even if nothing is done in this regard, the fear that it may be attempted will be sufficient to postpone many commitments. So far as the mining markets are affected, the only result is stagnation. The best-informed people in Wall Street regard the situation as certain to result in stimulating both the industry and the markets in time, for the reason that, in most part, mining and mining products are not affected by tariff schedules, nor by legislation relating to corporations. With several large combinations running the gauntlet of Federal investigation, and others marked for like procedure, the copper merger seems farther away than ever. Some of the preliminary mergers may not prove able to stand inspection. The opposition to the Calumet & Hecla consolidation has resulted in the filing of a bill for an injunction in the United States

Circuit Court, in Michigan, before Judge Swann, who has granted a temporary injunction against the merger. The chief allegation of the bill is that the proposed action is an attempt to form a monopoly and will create an unlawful combination of capital in restraint of trade. There is a late rumor that some of the banking interests involved in the consolidation are inclined to go no further with the matter, contending that the delay necessary to take the case to the United States Supreme Court will render present plans useless and that the ratios as now determined would all have to be readjusted. The copper situation seems not improving. Although the foreign visible supply shows a decrease of 422 tons, and curtailment of production is more in evidence now than it has ever been at any time since the so-called agreement was announced late last summer, the fact remains that there are several large companies getting ready for initial production, including the Ray Consolidated, Miami, Chino, Giroux, Mason Valley, Inspiration, and others. The operators of those properties cannot do things by halves, as the vast amounts expended in development and equipment compel production on a large scale. The weight of these factors and the low price of copper metal, with buyers indifferent, have dampened the enthusiasm for copper shares here. Utah Copper has been generally supposed to be fully financed and the stock distributed; nevertheless, the shares have been introduced to the French public, and it is reported that there is more activity in the issue in the Paris Coulisse than there is in the New York Stock Exchange. The Coulisse is the Parisian outside, resembling the New York Curb, but to a certain extent under the protection of the Paris Bourse. It is said that some 150,000 shares of Utah have been sold to the French public, in lots averaging between four and five shares to the stockholder. One of the characteristic phases of French frugality is the investment in small lots of stocks and bonds. Bonds prepared for the French market are always issued in denominations which bankers in this country would not handle, being too small to suit our ideas of finance. On the other hand, such odd lots rarely come back into the market, but are permanently held as investments.

The chain of Guggenheim dividends is to be distributed as usual. In regard to the Guggenheim Exploration Co., there has been no plan definitely accepted as yet for the reorganization of the company. One of the insiders said that "Eventually something will be done in the matter, for, although copper is selling at panic prices, and the Utah Copper Co. is not operating to capacity, while the Yukon Gold Co. ran at only 60% of capacity last year, the Exploration company is now earning at the rate of 18½% on its outstanding present capital." The company has a capital of $22,000,000, all issued save $1,206,700. Last year the earnings were 16.1%; for the year previous, 14.7%. The shareholders of the Live Oak Development Co. are to be given the right to subscribe for new stock at $20 per share on the basis of one share for each four shares they now hold. The new stock issue is underwritten by Hayden, Stone & Co. A contest waged for the control of the Barnes-King Development Co. resulted in a defeat for the present management, the control passing to Western men. At the present time the property is not being worked, but the company has some $270,000 in cash in its treasury, and Charles W. Goodale, general manager for the Boston & Montana, is to be elected to the presidency. Among the larger stockholders in the Barnes-King are Justice Gerard of the Supreme Court of New York, and H. Carroll Brown, a member of the New York Stock Exchange, both of whom are sons-in-law of the late Marcus Daly; John D. Ryan of the Amalgamated, and other officials of the same company. The present management stands accused of trying to acquire the present cash surplus of the Barnes-King by selling property to the company in which they or their friends are personally interested.

The report of Weed & Probert on the Ray Central property has just been made public, and is a little disappointing as to the ore available, estimated at 7,000,000 tons, averaging 2.15% copper. The cost-sheet showing 10.38c. per pound is a rather high cost for porphyry property, especially where there is no greater tonnage available. The engineers estimate that a plant of 1000 tons daily capacity can produce 9,155,000 lb. copper annually and earn dividends of $244,000, which would be 30.5c. per share on 800,000 shares, or equivalent to 20% on $1.50 per share. On this basis Ray Central hardly compares favorably with others developing porphyries.

JOHANNESBURG, TRANSVAAL

Output, Yield per Ton, Costs and Profits of the Witwatersrand Mining Co. in 1910.—Copper Field in Northeastern Transvaal.

The output analysis sheet issued by the Transvaal Chamber of Mines for December 1910 shows that during that month there was mined and milled in the Witwatersrand district 1,827,423 tons of ore, on which there was a profit of £952,574, being at the rate of 10s. 6d. per ton treated. For the 12 months of 1910, in the same district, 21,432,541 tons of ore was milled, the recovery per ton having been 28s. 6d. Working costs were maintained at an average of 17s. 7d. per ton, and the total resultant profit was, therefore, £11,216,105. It is interesting to observe that, in spite of the expansion of mining operations along the Main Reef, the aggregate profit earned by the Rand mining industry has of late declined. The grade of ore milled has dropped, and, despite working on a larger scale than ever hitherto, and despite economies and increased efficiency in details, which until lately were not much heeded, the profit for 1909 was less than that of 1908, and the 1910 aggregate in turn falls substantially below the 1909 figures. The following is a summary of the results obtained in the three years under review:

Year.	Costs per ton.	Profit per ton.	Total Profit.
1908	18s.	13.5s.	£12,011,227
1909	17.1s.	11.6s.	11,794,376
1910	17.7s.	10.6s.	11,216,105

An important copper field is now being explored in the northeast corner of the Transvaal, about 160 miles

Map of South Africa.

northeast of Pietersburg. The area in question, which is intersected by the Motale river, lies considerably to the east of the well known Messina mine, and the indications point to the probability of a big field being developed almost without interruption from the vicinity of the Seta mine, on the Limpopo river, to the Portuguese border. The geology of those new Motale fields differs essentially from that of the Messina area. In the latter the cupriferous areas, which are for the greater part chalcocite and malachite, occur in association with granite and gneiss, whereas at Motale the copper occurs in sandstones of the lower Waterberg age. Another feature of difference is that at Motale rich outcrops of both carbonate

and sulphide ore are found at the surface, but at Messina this is not the case. It is also worthy of remark that the extensive ancient workings so much in evidence at Messina are not to be observed in the Motale district, which seemingly indicates that the 'ancients' (whoever those estimable people may have been) and the natives knew nothing of the Motale field. The great handicap to the district now is the lack of efficient and economical means of transportation, but lines are being constructed from Pietersburg, and along the Selati route to the north, which will converge in the copper districts. When these projects are achieved, the northern portions of the Zoutpansberg district will be in a position to put large quantities of copper on the market at a reasonable cost of production. In connection with the Motale fields it is important to learn that a coalfield has been discovered

Motale Copper Field.

about 10 miles from the Malgo Syndicate's property. Other natural advantages of Motale fields are that they are in the heart of an area that is densely populated by native people, and that there is abundant timber and an ample supply of water in that region. Advantage is being taken of the present arrangements with regard to transport to send back return-loads of copper glance on the wagons. This ore, which averages between 40 and 45% of copper, is being accumulated at rail head (for the present, Pietersburg) and will be shipped to Swansea for smelting. Taken altogether, it appears that in this extreme northern portion of the Transvaal a copper field of considerable magnitude and value is being explored, of which a good deal more is to be heard in the near future.

BRITISH COLUMBIA

Railroad Building in Similkameen and Tulameen Country.— Platinum Placers.—Camp Hedley, Steamboat Mountain, and Sheep Creek.

Now that the winter is breaking, more men are being put to work on the Kettle Valley railway; about 15 miles of steel has been laid along the Coldwater river from Merritt, and about 30 miles of grading has been completed toward the summit and near the headwaters of the Coldwater. This line of railway is controlled by the C. P. R., and will connect with its Columbia and western branch at Midway, in the Boundary country, and when completed the rich copper camps of the Similkameen and Aspen Grove will have direct transportation to the Pacific Coast, and most of the Boundary and interior smelters will be supplied with coke, from both the Nicola valley and Tulameen coalfields, which will obviate the present long haul from the Crows Nest collieries. Early this spring railway construction will be pushed through this district by both the Victoria, Vancouver & Eastern (Great Northern) and the Kettle Valley (C. P. R.); both these railways should be completed within the year, and be in operation before the close of 1912. About 14 miles up the Tulameen river from Princeton, the new town of Coalmont is being established by the Columbia Coal & Coke Co., where home-seeking miners may reside when the production of coal and coke is begun. Coalmont takes its name from the mountain in which the 7 by 11-ft. tunnel is being driven to the measures of bituminous coal. Analyses have shown this coal to have excellent fuel and coking qualities. This company will erect 50 cottages on its townsite for the accommodation of its workingmen. In the tunnel good progress is made with three shifts. Andrew Laidlaw, of Spokane, recently closed two deals involving property in the Crows Nest Pass country, and a large area of coal land at Princeton, in the Similkameen coal basin, the latter known as the Princeton collieries which owns 18,000 to 20,000 acres of coal lands, including the surface rights to some 10,000 acres. The treasury stock of the company has been underwritten by the British Canadian Securities, Ltd., of Vancouver, B. C., assuring sufficient capital to equip and develop the property to a stage making it capable of producing 500 tons of coal per day.

With the price of platinum still on the advance, British and American investors are looking into the undeveloped platinum deposits of the Tulameen and Similkameen rivers, where in the early placer days platinum in commercial quantities was found in the sluice-boxes in a ratio of one to one with gold. In the last few years some of the most important deposits have been tied up by Government leases, and no development work to speak of has been done. Now, however, with the building of the V. V. & E. railway (Great Northern) up the Tulameen river, these platinum deposits will be developed by people having capital. No British Columbia mining camps have attracted more attention the past year than Sheep Creek camp, situated between Nelson and the international boundary line; Camp Hedley, situated in the centre of the Similkameen; and the gold discoveries on Steamboat mountain, and Siwash creek, situated in the Hope mountains. Steamboat mountain is situated on the Skagit river near the headwaters of the Tulameen river; and Siwash creek heads in the Coquihalla mountains, about 60 miles north of Steamboat, and flows into the Fraser at Yale. The distributing points for Steamboat region are Hope

Nickel Plate Mine, Hedley, B. C.

and Princeton. In the Sheep Creek camp, the Queen mine, operated by a Wisconsin company, ran its 20-stamp mill last year without a shut-down. The Nugget mine at the summit of Dominion mountain, owned and operated by the Nugget Gold Mines, Ltd., operated its 4-stamp mill throughout last year, producing concentrates, which were rawhided out this winter. After about three years of steady development work, the Mother Lode mine has changed hands and is now the property of John McMartin of Cobalt and his associates. A new mill is being erected, and ore shipments are expected to be made this season. The Kootenay Belle mine, which was purchased last year by the Rogers syndicate, will probably enter the shipping list this season; it is situated on Yellowstone mountain, across from the Mother Lode, but farther down Sheep creek. Some promising properties have lately been bonded, and many new companies have been formed to develop claims in the Sheep Creek district.

Camp Hedley still leads in the gold production of southern British Columbia, the Nickel Plate mine having produced more gold than any other gold mine in Canada. The Pollock Mines, Ltd., has a deal pending with London investors. The Brown Mines Development Co. recently was organized to develop the Bull Dog group which ad-

joins the Crown Point group. Hedley is not a poor man's mining camp, owing to its hard formation, the thorough development of the majority of the promising prospects requiring a considerable expenditure of money. The Hedley Gold M. Co. has a 40-stamp mill and cyanide plant; it also boasts of owning and operating the longest gravity tramway in the world. No doubt, when outside capital becomes interested in the Similkameen, Camp Hedley will have many gold mines as good as the present producers. The recent rich gold finds on Steamboat mountain and the discovery of free-milling gold ore on Siwash creek have attracted attention in Vancouver where people are interested. With the development work laid out for this summer on both Steamboat mountain and Siwash creek, those camps may show many more producing mines to the credit of Yale district, and it is hoped that the wild-catting which so hampered the legitimate development of the Rossland and Trail creek camps some fifteen years ago will be entirely suppressed by the different mining journals of Canada and the United States, and by the co-operation of investors in legitimate mining throughout the entire province. The Provincial Government last week sent a party of surveyors to lay out a new road from Hope to Steamboat mountain, and from the new mines down the Similkameen to Princeton.

REPUBLIC, WASHINGTON

Spirited Contest Between Factions of the New Republic Mines Co. — Transfer to Rathfon Reduction Works.—The Black Tail Mine.

The annual meeting of the New Republic Mines Co. was held at Republic March 1. Of the capital stock of 2,000,000 shares, 1,920,000 shares were represented in person and by proxies. A contest took place between the majority and minority factions for supremacy, occasioned by the issue of 114,500 shares of the treasury stock to John De Young, four days previous to the meeting, for the purpose, it was claimed, of controlling said meeting. A fierce debate ensued when the minority report came up for consideration, which lasted from the middle of the afternoon until nearly midnight, when the minority faction, headed by J. L. Harper, J. E. McFarland, and G. M. Fripp, bolted the meeting. The debate related to the transfer of the company's property to the Rathfon Reduction Works, a corporation in which some of the directors were alleged to have been interested. The minority leaders made charges of fraud and bad faith on the part of the officers, claiming that in the matter of this transfer they had served their own interests instead of those of the company. Several of the 35 members present called on the officers to answer the charges against them, and the trustees' attorney said they would not report to the meeting, but would defend themselves in the Superior Court of Ferry county, where an action is pending for the annulment of the transfer of the company's property. A crisis was precipitated when Mr. McFarland, addressing himself, as a stockholder, to F. B. Babcock, as the president of the company, asked: "Did you, at the time you entered into this deal, last September, or did you not, favor your own private interests by being interested in the Rathfon company and exacting terms from me, as a stockholder, on a basis unequal to your own? In other words, did you not have an ulterior motive to my detriment in the transaction?" Mr. Babcock refused to answer the question. The meeting voted in favor of passing the annual reports of the officers and having them filed with the secretary and held accessible to the stockholders. A resolution was adopted approving and ratifying the contract for the sale and transfer of the company's lease of the Republic mine and personal property to the Rathfon Reduction Works. The following were elected to serve as directors for the ensuing year: F. B. Babcock, R. J. Howard, John De Young, A. Babcock, F. W. Bewley, O. B. Hollis, W. J. Burns, F. Kienbaum, and W. B. Parker.

The frame-work of the North Washington Power & Reduction Co.'s mill building will be ready for the installation of the machinery by March 10. The Black Tail mine, owned by the Hope company, looks better than at any time since it was purchased, last July. The winze on the Black Tail vein is down 60 ft. below the adit-level. The company has arranged for the installation of an air-compressor and hoist, good for a depth of several hundred feet. At the bottom of the winze a pay-streak over 30 in. wide has been developed which assays from $50 to $70 per ton. From a point 462 ft. in from the portal of the adit a drift has been driven northwesterly about 300 ft. From the end of the drift a cross-cut will be started toward the Black Tail vein, with the expectation of intersecting it within a distance of 50 ft. The company has ordered 1400 ft. of T-rails for new trackage.

TORONTO, CANADA

Deputation of Mining Men Ask for Railroad to Gowganda District. — Bewick-Moreing Representatives Invest in Porcupine.

Premier Whitney and other members of the Ontario Government were interviewed Feb. 15 by a delegation of about 500 mining men and others interested in the development of the Gowganda silver area, urging the building by the Government of a railway to open that district, and the intervening Elk Lake area, and connecting them with the Temiskaming & Northern Ontario. The argument presented was that a large amount of money had been invested in mining development, but that the ore extracted, being mostly low grade, could not be profitably shipped without railway facilities. It was represented that by the construction of the projected road a great impetus would be given to mining development and production. While the tone of the replies given by the Premier and the Minister of Mines was favorable, no definite promises were made, and it was intimated that before a decisive answer was given the Government would require to be furnished with more precise information as to the tonnage of ore that might be shipped from the mines. As an alternative proposition, should the Government not see its way to construct the branch as a public work, the deputation asked for the issue of a charter to a private company, coupled with an agreement on the part of the Government that it would not in the future build a competing line. The general feeling is that the Government, before long will either build the road or grant the required charter.

The representatives of the Bewick-Moreing company of England who visited Porcupine have taken over for development 50 claims belonging to the Timmis-McMartin-Dunlop syndicate, on which they will expend $500,000 during the coming season. These locations do not include the Hollinger or the Miller-Middleton groups of claims. This has considerably stimulated activity on the part of others, and the camp is active. Reports from the Hollinger are encouraging. The orebody is stated to have been proved down to 200 ft. and for a length of 1200 ft. on one vein. A portion of the machinery for the 30-stamp mill is on the ground, and it is expected that it will be in operation by July 1. In the meantime the stock has advanced and is now selling around $6. On the Rea mines, operated by the Consolidated Gold Fields, the diamond-drill shows free gold at a depth of 200 ft. The Standard Mining Co. has good showings at the bottom of a 20-ft. shaft and will start diamond-drilling to prove the property at depth. The Preston East Dome Co. has let contracts for sinking four shafts and has ordered a 30-stamp mill. Notwithstanding severe winter conditions, good progress is being made building the Porcupine branch of the railway, with a force of about 900 men. Snowshoe prospecting has been active during the winter in the district and a large number of claims has been staked on the chance of finding ore in the future. A syndicate including Fred Tiffany, of New York; Thomas E. Savage, Boston; John B. Barlow, Hartford, Conn.; Richard D. Isaacs, St. John, N. B.; and H. D. Hadley, New York, have purchased four Porcupine claims for $200,000, and will form a company capitalized at $1,500,000.

General Mining News

ALASKA

Road and trail-building, accomplished in Alaska up to the end of 1909, is stated in the Governor's report as follows: Wagon-roads, 720 miles; winter sled-roads for two horses, 472 miles; for single horse or dog-sled, 551 miles; trails, marked by permanent iron stakes, 85 miles; marked by temporary stakes, 670 miles. This work, with maintenance work, represents an expenditure of $1,487,911, most of which was derived from appropriations by Congress and from the Alaska fund, though $75,000 to $100,000 was local road-tax funds, and voluntary contributions. This road and trail-building has been done under direction of the Alaska Road Commission, acting under the authority of the Secretary of War. One of the most important road and trail routes is the one between Valdez and Fairbanks.

PRINCE WILLIAM SOUND

It is estimated that 500 people arrived at Valdez in February, attracted thither by the prospect of mining activity in that region during this season. The snow is not expected to begin to melt on the hills till May, and miners going there early are warned that work on the new properties will not begin till June or July. A rush of people to Valdez, however, is anticipated.

Ellamar Mine, Prince William Sound.

ARIZONA

COCHISE COUNTY

The Tombstone Con. Mines Co., which for the present ceased operating on its own account a few weeks ago, has let leases to 26 parties, assigning a certain place in its Tombstone mines to each lessee. The lessor allows these parties the use of its haulage levels, shafts, cages, hoists, boilers, cars, and other equipment, and is to receive as royalty 20% of net smelter returns from ore shipped by lessees. The company has reserved the right to terminate the leases at the end of six months, by giving 60 days notice. The Middlemarch Copper Co. is to resume operations on its property in the Dragoon mountains.

GILA COUNTY

Henry Krumb, consulting engineer for the Inspiration Copper Co., is reported as having stated that this company's demonstrated ore zone has a width of 1400 ft. and a length of 3400 ft., and that the work of four churn-drills is serving to enlarge this area. For the purpose of developing and mining the ore lying below the main transportation level, the Colorado and Joe Bush shafts are being sunk 220 ft. below that level.

(Special Correspondence.)—Because of delay in shipment of a minor piece of machinery needed at the power plant, the Miami Copper Co.'s concentrating plant did not begin its treatment of ore on March 1. It may be the 10th of this month before the mill begins its work. F. W. Solomon, until now with the Nevada Consolidated at McGill, Nevada, arrived at Miami, February 28, to assume charge of the Miami concentrator. Units No. 2 and 3 will be the first to be put in operation. They have been given a try-out and most of their stiffness has been eliminated. Because of the limited power furnished by the old generator used in construction of the plant, it has been impossible to operate more than a portion of a unit at one time. It was the intention of the management to make the preliminary run with units No. 3 and 4, but No. 4 is being equipped with the Burch fine rolls instead of the Chilean mills used in connection with the other units, and a portion of the rolls has not yet arrived. The pumping plant at Burch was given a trial run March 1 and found to be without any defect. The water-line from the pumps to the mill has been temporarily laid with 10-in. casing until arrival of the 14-in. pipe that will be used for the permanent main. The pipe-line that will be used to convey hot air between the power-house and heating-house at No. 4 shaft has been connected. One of the new hoisting engines also was tried March 1. It was found satisfactory, and will be operated daily to lessen frictional stiffness and familiarize the engineers with the machinery and shaft measurements. A transmission-line is being strung between the power-house and the concentrate tanks, situated in the canyon west of the concentrator, to operate the vacuum-pumps that will be employed to dry the concentrate before being stored in the bins. Three churn-drills are still being used by the Miami company. One is employed on the western end of the property for the purpose of determining the exact line of demarcation between the orebody and barren ground that all unnecessary underground work may be obviated. The other drills are engaged in exploration work, one drill sinking on the extreme northwestern portion of the property adjoining the Inspiration ground, the other drilling on the high ground of the Red Springs claim, having been moved recently from a point in the gulch on the same claim.

Globe, March 4.

MARICOPA COUNTY

The Arizona Bureau of Mines has been organized at Phoenix, the object of which is to compile statistics of Arizona mines, to collect specimen ores for exhibit, to maintain a publicity bureau as to mining progress, to establish a mining library, to outline and propose legislation in the interest of mining, to suppress wild-cat schemes, and to organize a Territorial bureau to co-operate with the Federal Bureau of Mines.

YAVAPAI COUNTY

The United Verde Extension Co., operating at Jerome, is to ship ore to the smelter at Swansea, Yuma county. It is estimated that the ore to be shipped will sample 5% copper and $8 per ton in gold. The Jerome-Durango Gold M. Co. recently held a meeting in Jerome, at which the 60 stockholders present raised the necessary money for the purchase and installation of a 5-stamp mill. The company has 600 tons of high-grade ore on the dump, and several thousand tons exposed in the mine. It is claimed this ore assays $140 to $150 per ton in gold and silver. The shaft of the Jerome Verde Copper Co. has a depth of 600 ft., and the intention is to sink 100 ft. deeper, then drive to the orebody at that depth.

CALIFORNIA

BUTTE COUNTY

According to data supplied by M. J. Cooney, one of the owners of the Gold Queen and Shakespeare mines, in the vicinity of Forbestown, the gold production of Butte county mines between 1849 and 1899 was $270,000,000. The Gold-

bank mine, at Forbestown, has been sold by H. S. Stowe to M. J. Cooney and F. J. Stoers, who have acquired other mining property in that district. The Goldbank has been one of the largest producing mines in the county.

CALAVERAS COUNTY

The Copa de Oro M. & M. Co., owner of the Blue Bell quartz mine, situated near Glencoe, has developed the property considerably and may erect a mill this season. The mine is on the south fork of the Mokelumne river, and its veins of ore are being opened by a cross-cut that was started in the river canyon. A mill can be operated by water-power, and the ore can be moved to the mill by gravity.

The farmers living in the vicinity of Campo Seco have formed an association to oppose the Penn Chemical Co. in the operation of its copper furnaces and roasters, claiming the fume emitted into the atmosphere is detrimental to plant-life and health.

ELDORADO COUNTY

Robert Waugh and A. A. Goldsberry, of Auburn and Sacramento, respectively, are opening a channel of auriferous gravel near Georgetown. This channel is reported to have a width of 600 feet.

INYO COUNTY

(Special Correspondence.)—The Skidoo Mines Co., for the month of January, milled 1070 tons of ore in 18½ days, recovering bullion of the value of $14,635.67. The operating expenses amounted to $6592.25; development work cost $813.31. The net profit for the month was $7230.11.

Skidoo, March 3.

KERN COUNTY

The Spangler mine, situated in Radamacher district, is being operated by a small force of miners, and ore assaying $125 per ton is being mined on the 125-ft. level. This is sacked and shipped to the smelter. Radamacher is the name of a station on the Southern Pacific's Mojave-Owen's Valley line. The Butte mine, at Randsburg, is active in the hands of lessees. Ed. Shipsey, principal lessee, has let a number of sub-leases, but is mining on the new vein, opened last September, with his own force, having installed a 12-hp. gasoline hoist for this work. A number of the sub-lessees are working in ground tributary to the main 600-ft. shaft. James Rice, to whom a lease was given on the King Solomon extension of the new Butte vein, has sold his interest therein to W. Halladay. Rice then obtained a lease on the old vein of the Butte.

MARIPOSA COUNTY

The Bullion Hill M. Co. has let a contract to the Jardine Machinery Co. of San Francisco for the erection of a 75-ton mill at the former's mine at Exchequer. The equipment is to include a Krogh tube-mill, Huntington grinders, and amalgamating-plates. The machinery is to be driven by two Union gas-engines.

NEVADA COUNTY

The *Grass Valley Union* states that the Rose Hill mine is to be put in operation again. This property, which was operated formerly, has a surface area of 1100 by 600 ft., and contains two defined, parallel veins, and the ground is patented. Development consists of an 860-ft. cross-cut by which the two veins are intersected, and by a 125-ft. incline, the latter connecting with the south drift on one of the veins. The Midas mine, situated near Randolph flat, which was developed to some extent by James brothers of Grass Valley, is to be unwatered, so that its workings may be examined. Money to pay the expenses of pumping has been provided. The sale of the property to San Francisco people is anticipated.

PLACER COUNTY

The Herman mine, situated at Westville, and controlled by Pittsburg men, is to be operated again this season under the superintendency of E. B. Quigley. This is a gold quartz mine and has paid dividends. The Haskel gold-gravel mine, near Auburn, is to be worked during this season by E. C. Gaylord and H. T. Power.

PLUMAS COUNTY

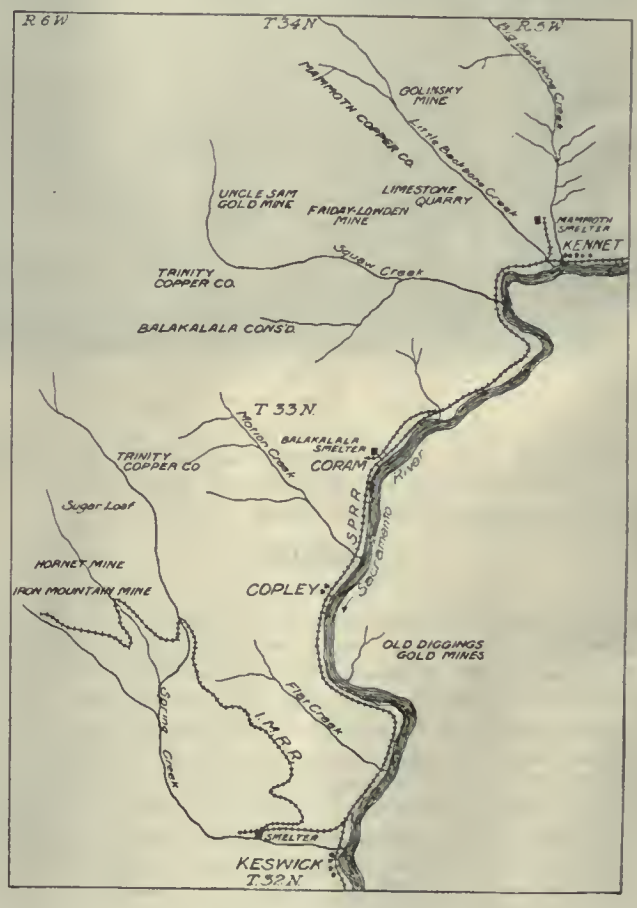
The discovery of a new vein of gold-bearing quartz in the Jamison mine is likely to give that property an extension of productiveness. It has been operated during the last 15 years, and just previous to this find it was thought its orebodies were nearly exhausted. There is a 20-stamp mill at the mine, and the building of a new mill may be considered. Its location is near Johnsville. The Plumas-Eureka mine is being operated under direction of J. Lawton, who is having a cross-cut driven from the Eureka tunnel to open the ore in the 'Seventy-six' workings. While this mine was formerly considered worked out, recent development is said to be demonstrating that it has sufficient ore to keep the 40-stamp mill operating for some time. The broken wire-cable of the tramway is being replaced by a new one.

SAN BERNARDINO COUNTY

The Saxony Mining & Development Co. has been incorporated to mine and market tungsten ore on a property which has been developed to some extent by George Reidrich, who is a stockholder in the company. The property is situated near Atolia.

SHASTA COUNTY

The Shasta Copper Exploration Co. has nearly 1000 acres of mineral land situated between the Balaklala and Iron Mountain mines. A consolidation of various properties,



Copper Region of Shasta County.

making up this group, was effected by M. E. Dittmar. The directors of the company are W. P. Hammon, M. E. Dittmar, Frank H. Buck, W. L. Leland, and O. Scribner. Extensive exploration with diamond-drills is to be undertaken. The company's office is to be in San Francisco. The Redding Engineering Works Co. has purchased a carload of pig iron turned out at the Heroult electric smelter, where the output amounts to 25 tons per day with one furnace in operation.

The First National Copper Co., owner of the Balaklala mine and smelter, at Coram, produced 9,911,451 lb. of copper, 456,487 oz. silver, and 10,389 oz. gold as the result

of its 1910 operations. It cost 11c. per pound to produce copper. The company expended over $100,000 in installing equipment for the Cottrell electric precipitating system, by the operation of which it is succeeding in eliminating 90 to 95% of the solids from the furnace fume. One blast-furnace and one reverberatory are being operated. Its January output amounted to 932,452 lb. copper, 41,232 oz. silver, 822 oz. gold. The result of last year's development was a gain on the ore reserve, now estimated at 2,000,000 tons. The average assay of the ore shows 2½% copper, $1 per ton in gold and silver.

SIERRA COUNTY

The Omega auriferous gravel mine, situated between Forest and Mountain House, is bonded to a company of which W. W. Clark is president. The gravel mill is not to be operated, as it has been supplanted by an electrical machine for recovering the fine gold, the coarser gold to be saved in sluice-boxes. This machine is said to have the capacity to handle 120 cars of gravel in 24 hours. The work is in charge of W. W. Casserly. The Monte Cristo Gravel Mines Co., of Oakland, is successfully operating on a property that it took under bond from Peckwith & Spaulding. The pay channel in which work is being done is said to be 20 ft. wide. The operations are in charge of Fred I. Phelps.

TUOLUMNE COUNTY

(Special Correspondence.)—The Black Oak mill has been started on ore from the rich shoot recently uncovered at the bottom of the mine, and a carload of high-grade ore was this week sent to the Selby smelter. The orebody is said to be one of the best ever found in that mine, both in size and richness. It is reported that gravel which yields $3 per mine-car is being mined at the Water Lily, situated near Melones. Lightning struck the transformer-house at the Jumper mine on February 23, causing its complete destruction by fire. As a result, work in the mine had to be stopped until new transformers were installed, which were obtained from the Cilo mines. Preparations are being made for the erection of a 10-stamp mill at the Contention mine, in the Knight's Creek district. The lumber necessary for this and other buildings to be put up is being sawed on the property, where a small mill is in operation. A score or more men are employed. Some work is being done at the Draper mine under the direction of R. A. Nicholls, the superintendent.

Development work has been resumed at the Birthday mine, situated near Tuttletown, and owned by local people. An adit is being driven on the vein. The Badger mine, comprising several claims, and lately sold to A. L. Ellis, of Gilroy, is to be unwatered at once, preparatory to active development operations. The property is situated about four miles northwest of Jamestown.

Tuolumne, March 4.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—It is reported that the deal for the purchase of the Scepter mine on Democrat mountain will be closed within the next two weeks. The price is understood to be $100,000. A streak of galena 18 in. wide has been uncovered by the Vidler tunnel in East Argentine district. Driving is to be started for the exploration of the ground. The bore has been advanced over 5000 ft. from the eastern side of the pass. There remains to be broken 1600 ft. of ground before the connection will be made.

Georgetown, March 1.

(Special Correspondence.)—A. L. Lawson, representing the McKelvey process of ore reduction, has been endeavoring to secure contracts with operators, and in the event of a stated tonnage of ore being promised, a mill will be erected. A shipment of 700 tons of ore from the Refugee mine to the Hudson mill was made last week. The Katie Emmett mine is to be equipped with a 5-stamp mill, the machinery having been purchased a few days ago in Denver. W. W. Cannady is manager. R. F. Staley has purchased the Dover mill, situated on lower Fall river. The machinery will be overhauled and the plant put in good condition. H. B. Clifford, who is operating the Gem mines, has acquired the Castleton. The shaft, down to a depth of 425 ft., is to be repaired, while a lateral will be driven from the Crown Point vein.

Idaho Springs, March 1.

GILPIN COUNTY

(Special Correspondence.)—Ore is being shipped from the Newfoundland mine to the Iron City mill. This ore is being mined on the twelfth and thirteenth levels. A. H. Rose is manager. The new mill of the Denver Reduction Co. is operating. The Clay County mine is being developed by work on the 500-ft. level west. Reese & Co., leasing on the 600-ft. level of the Saratoga mine, made a shipment of 30 tons of smelting ore last week that brought $25 per ton in gold and silver. The shaft on the Baxter mine has attained a depth of 362 ft., and stoping is in progress on the 140-ft. level; a body of mill-ore is being followed that is from 3 to 4 ft. wide. G. R. Gibson is manager.

Central City, March 1.

LAKE COUNTY (LEADVILLE)

The zinc buyers, who changed their schedule so as to effect a reduction from $11.30 to $8.80 per ton to producers of ore running 30% zinc, have receded from their position and re-established the former schedule. The attempt to reduce the price to the miner by means of an additional treatment charge resulted in a suspension of some of the larger mines. Now that the old schedule has been agreed to, the mines are all producing again. The Continental Chief mine, situated at the head of Iowa gulch, is under lease to local men, who are mining and sacking ore which will not be marketed till later in the spring, as this camp is isolated by heavy snowdrifts. This ore contains gold, as well as silver and lead. Among the Fryer hill properties which are active are the Chrysolite, Little Chief, Hayden, McRae, Amy, Dunkin, Climax, Virginius, Silver, Matchless, and Pittsburg, and the majority of these are ore-shippers. The mines on Carbonate hill, including the Waterloo, Maid of Erin, Henriette, Adams, Wolftone, and Castle View, resumed operating March 1, as the result of the adjustment of the zinc schedule between the ore buyers and the operators. This schedule related to the zinc-carbonate ores, and it is stated by the *Carbonate Chronicle*, of Leadville, that the tonnage of zinc sulphide ore being shipped out of the camp is small, and will not increase rapidly pending the building of new zinc smelters in Oklahoma.

SAN MIGUEL COUNTY

C. E. Cherrington, who is mining vanadium ore at Newmire, has entered into a contract with the General Vanadium Co. of London, whereby he undertakes to ship to Liverpool 200 tons of ore per month. The price agreed on is said to be $1 per pound for the metallic vanadium contained in the ore, or $60 per ton for ore running 3% vanadium. The deposits of this kind of ore at Newmire are extensive, and it is claimed 10 or 12 operators are engaged in mining there.

TELLER COUNTY (CRIPPLE CREEK)

The gross proceeds of the Elkton Con. M. Co. for the last 10 months of 1910 amounted to $720,944; the operating costs amounted to $450,421, the net profit being $279,876. During that period the dividends aggregated $387,500, and there was a balance in the treasury Jan. 1, 1911, of $537,988. The water-level in the Elkton mine stands at about 30 ft. above the lowest level, and this is receding at the rate of 2 ft. per week. Recently the company has been operating with but one shift of miners per day, six days per week, but it is understood that there will soon be two shifts. The shaft is to be sunk deeper as fast as is practicable. The year's achievements were accomplished under the management of E. M. DeLavergne.

SUMMIT COUNTY

The mill of the Colorado-Toledo M. Co., now nearly fin-

ished, is equipped with a No. 5 Austin gyratory crusher, automatic sampler, revolving screens, coarse rolls, jigs, hydraulic classifiers, Card tables, fine rolls, and is designed to make jig and table lead concentrates, and an iron-zinc middling. The property is at Argentine. The Colorado Gold Dredging Co., operating on Swan river, near Breckenridge, kept one dredge at work steadily during the dredging season, and another part of the time. Additional dredging ground has been acquired, and it is probable that both machines will be operated steadily during the 1911 season. The dredges handled 1,400,554 cu. yd. of gravel last season, at a cost of 4.7c. per yard. This material yielded 25 to 45c. per yard in gold. One dividend of $50,000 was paid in 1910.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.) — The Federal Mining & Smelting Co. will disburse its regular quarterly dividend of $210,000, on its preferred stock, March 15, which brings the total dividends to $8,719,750. The company owns and operates three groups of mines in the Coeur d'Alene district. An important ore-zone was opened in its Morning mine at Mullan, which gives promise of becoming one of the most profitable of the company's hold-

Mountain Scene in the Coeur d'Alene.

ings. Coeur d'Alene Nellie mine, near Kellogg, operated by the Wallace Development Co., for which E. C. Melklejohn is manager, is becoming a producer of silver-lead ore, instead of being a dry-ore property. It was formerly active and has netted profits of about $100,000. The lower tunnel, in 100 ft. when the present owners took charge, has been advanced 325 ft., and at the face, 200 ft. from the surface, there was 30 in. of ore averaging 100 oz. silver and 4% copper. The pay-streak is on the hanging wall side of the vein and has been explored for several hundred feet ahead of the new workings. On the foot-wall side is said to be a body of concentrating ore that samples 3½% lead. Tam O'Shanter, near Osborne, will be further developed this season. A shaft has been sunk 50 ft. from the apex and a cross-cut at the base of it shows the vein to be 18 ft. in width. The vein has been traced 6000 ft. Two adits are being driven, each one being in about 200 feet.

Wallace, March 3.

NEVADA

ESMERALDA COUNTY

The Combination Fraction mine, at Goldfield, is under a 15-months lease to M. B. Ashton and associates, who are required to sink 150 ft. deeper the 750-ft. shaft. The work is to be in charge of A. E. Camphell. The Florence-Goldfield M. Co. has declared a dividend of 10c. per share, amounting to $105,000, payable April 2. The Centennial mine, 3 miles from Lida, an active and profitable silver mine 20 years ago, has been purchased by San Francisco investors at $10,000. The new owners, who had previously spent considerable money in exploring and developing, expect to operate the mine this season.

HUMBOLDT COUNTY

W. G. Adamson and John R. Turner, who recently discovered high-grade gold ore in a 50-ft. dike, 5 miles from Winnemucca, are reported as having shipped 10 tons of their richest ore to Salt Lake by express.

LANDER COUNTY

The Austin-Manhattan M. Co., made up of Chicago men, a few years ago acquired mining property on Lander, Union, and Central hills, at Austin. These were operated at a profit in early mining days, and contained such veins as the Panamint, Union, and Patriot. Within the last two years the old drainage level has been cleaned out and retimbered for a distance of over 6000 ft., at a cost of $100,000; and the main cross-cut driven from this drainage level was cleaned out for a distance of 1300 ft. The Frost shaft has been cleaned out and retimbered from the collar to the tunnel-level, a depth of 700 ft., and has been sunk 250 ft. below that level as a 3-compartment shaft. A station was cut where this shaft and tunnel intersect, and here a counter-balance hoist was installed to operate skips in the lower section of the shaft. The Ophir shaft, which has been retimbered to a depth of 200 ft., is to become the main working shaft for the Union vein system. The Jack-Pot group, adjoining the main properties, has been purchased and its gold-bearing veins developed to a depth of 400 ft. In the meantime a concentrating-plant, designed by the Huff Electrostatic Separator Co., has been built and set in operation. Crude ore shipped to the smelter has sampled $126 per ton, and the concentrate shipped recently assayed $134 per ton. This work has been performed under the management of W. W. Wishon.

MINERAL COUNTY

The Douglass group of claims, situated in Gold range, near Mina, is to be developed by a 1000-ft. shaft, which is being sunk. This property is owned by Pennsylvania men, with whom C. D. Van Duser of Nevada is associated. The Douglass has been equipped with a 5-stamp mill for use in prospecting, developing, and proving the property as to its merits. G. B. Hyde, having a lease on one of the Van Duser properties, is preparing to erect a mill.

NYE COUNTY

The Tonopah Belmont Development Co., operator of the Belmont mine and mill, for the month of January sent 6839 tons of ore to the mill, marketed 2053 tons at the smelters; the gross production from both classes of ore was 3860.3 oz. gold, 386,409 oz. silver, of the gross value of $288,902.92. The net profit for the month was $159,511.39. The average value of metal extracted was about $32 per ton.

The Big Four Leasing Co., operating the Big Four mine and mill at Manhattan, recently made a mill-run of 1150 tons of ore, the clean-up as a result amounting to $50,000. The treated ore was taken from the 220-ft. level. The gross output of the last year was $150,000.

The coroner's jury, which enquired into the facts relating to the Belmont mine fire at Tonopah, and the manner in which 17 men met death, rendered the following verdict: "We believe from the evidence adduced that the management and bosses showed lack of knowledge and experience in such emergencies, and also inability to foresee and realize that serious danger might arise from such a fire."

STOREY COUNTY

The Ophir, Con. Virginia, and Mexican mines, the largest three north-end producers of Virginia City, yielded ore of the aggregate value of $22,715 for the week ended March 4. Of this, the Ophir production amounted to $12,126. There were 319 cars of ore, averaging $30.67, taken from the 2100-ft. level; 85 cars, averaging $17.43, came from the west cross-cut No. 2, same level; 57 cars, assaying $15.09, was mined on northeast stope, 2300-ft. level. Average per ton of all lots of Ophir ore was $26.30.

The Con. Virginia mined 283 cars on the 1800-ft. level, assaying $10.20 per ton, making an output of $2888.60. The Mexican mine produced 122 mine-cars of ore, assaying $63 per ton, yielding $7700. This ore was mined from the stopes and raises just above the 2500-ft. level, where

Con. Virginia Shaft.

the orebody is about 12 ft. wide. Driving is being done to open this ore-shoot on levels above the 2500-ft. The Yellow Jacket mill, having resumed operations on Feb. 28, crushed 279 tons of ore from the Crown Point mine, and 94 tons from the Belcher.

OREGON

GRANT COUNTY

The Red Boy mine and mill were active properties ten years ago. They are situated 4 miles from Granite and 18 miles from Sumpter. The mine, which was a gold producer, is well equipped and considerably developed to a depth of 400 ft.; the mill is equipped for concentration and cyanidation and was operated several years with considerable success. Most of the success was attained during the ownership of Clark Taber and E. J. Godfrey. The vein system, having a north-south strike, is cut off by a dike, and only recently was a vein opened on the south side of this dike. The ore found in this vein is said to be of high grade. If orebodies to be found south of the dike prove as rich as were those worked out on the north side, the Red Boy will have another period of productiveness.

UTAH

SUMMIT COUNTY

The orebody recently discovered in the New York Bonanza mine, at Park City, consists of an 18-in. streak of clean ore that assays $40 per ton. Some shipments have been made to the smelter. M. J. McGill is in charge, and the property is in the hands of Park City people, mostly.

Henry M. Crowther and associates, who have operated the Ontario mine during the last two years on short-term leases, have organized The Crowthers Company, to which this property has been leased for a period of 10 years. During the last two years these lessees made 160 shipments of 1 to 4-car lots of ore, considered average high-grade stuff for Park City district. But it is estimated that the Ontario workings contain 1,000,000 tons of second-grade ore, which accumulated during the years when the mine produced such high-grade ore, and it is found in old stopes and other places as filling. As a test of its value, several thousand tons have been shipped to the smelter, and the result is considered such as to justify the handling of it on a large scale. It is said 80% of this ore is found above the main tunnel, and can be extracted without hoisting. The content of the ore is principally silver, which is accompanied by gold in small value, and about 2% lead. The new company intends to modernize the old mill, and establish a system of electric-haulage in the mine where there are 60 miles of trackage. One feature of the mill-work is to be the cyanidation of the ore after the lead has been eliminated by concentration.

TOOELE COUNTY

The Utah Metals & Mining Co. is driving a tunnel from Middle canyon, on the Tooele side of the Oquirrh range, to Bingham canyon, on the opposite side. The size of the bore is 8 by 10 ft. cross-section, designed to give room for a double track. The heading has advanced about 5000 ft., and the cutting of profitable ore-bearing veins is anticipated. One object of this enterprise is to make an avenue for transportation between Bingham mines and the International smelter near Tooele.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—A recent statement of the B. C. Copper Co. shows that the profit on its operations amounted to $256,561.58 for the fiscal year ended Nov. 30, 1910. During the period named the metallic production was: copper, 7,143,456 lb.; silver, 84,180 oz.; gold, 24,962 oz. The company treated at its smelter at Greenwood 441,672 tons of ore, which yielded 18 lb. copper and $1.23 gold per ton. Most of this ore was from its own mines. The total mining costs per ton amounted to $2.73. The cost per pound of making copper, including cost of mining, smelting, and marketing, was 9.048c. The new Granby management announces present costs, not including marketing and refining the blister-copper, at approximately $2.39 per ton of ore. The cost of making and marketing copper is close to 10c. per pound. This figure compares favorably with the previous five years. This company is now producing copper at the rate of 20,000,000 lb. per annum, and this output may be increased.

Phoenix, February 25.

(Special Correspondence.)—The Steele interests in Vancouver have disposed of several rich mineral claims on Hudson Bay mountain, Hazelton district, for $300,000. English capitalists secured the properties, which have a rich showing of galena ore. The International Mining Co. of Portland Canal is to drive a permanent working tunnel. A contract has been let for 50 ft. of driving on the vein. Last week the Portland Canal Mining Co. opened high-grade ore in No. 3 adit. The vein is 5½ ft. wide, and 150 ft. of backs is available for stoping. This ore assays $12 gold and $4 silver per ton. Preparations are being made to ship some of its concentrate, and the capacity of the mill is to be increased. It is now 75 tons per day. A vein of galena ore, 18 in. wide, was opened in the Stewart mine recently. Ore found in No. 4 tunnel will assay $50 per ton. The directors of the Red Cliff Mining Co. have let a contract to F. Darling & Co., Vancouver, for the installation of a water-power plant for operating the air-compressor and generator. This will consist of 36 and 15-in. impulse water-wheels and a pipe-line. Three veins have been opened on the Main Reef group—one for over 400 ft., the ore therein assaying $50 per ton in gold, silver, and lead. The company has a lot of good ore sacked awaiting the completion of the Portland Canal railway. A crew of 23 is employed on the Ben Bolt property, of the D. D. Mann interests.

Vancouver, February 23.

(Special Correspondence.)—W. E. Zwicky, manager of the Rambler-Cariboo mine, near Kaslo, has recommended that the mill be moved from its present location to a point below the mouth of the main cross-cut tunnel on the 1400-ft. level. This would involve the construction of a tramway from the main tunnel to the mill. He believes recent developments on the various levels justify improved equipment. The showing on the 1050-ft. level, for more than 60 ft., averages 5 ft. of clean ore that runs 250 oz. silver and 70% lead.

Kaslo, March 2.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The Republica M. Co. mined and milled 1067 tons of ore in January, producing metals valued at ₱72,262.80. Operating expenses and development costs amounted to ₱50,858.27; construction expenditures were ₱5735.63. Working is severely handicapped, and costs increased by the exigencies of the political situation.

Ocampo, March 1.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

M. L. REQUA is in New York.

J. H. MACKENZIE is leaving for Nicaragua.

F. OSKAR MARTIN was at Goldfield last week.

J. PARKE CHANNING was at Miami last week.

FREDERICK P. BURRALL was in San Francisco.

C. B. LAKENAN was in San Francisco March 4.

W. A. PRICHARD is now at Santa Cruz de Alaya, Sinaloa.

A. G. BLAKE is in Jalisco, Mexico, for a couple of months.

GEORGE E. FARISH passed through San Francisco this week.

FRED L. LOWELL is engineer at the Adargas mine, Jimenez, Mexico.

STEPHEN A. IONIDES, of Denver, has been in Redding, California.

J. E. SPURR was in Santa Eulalia district, Chihuahua, in February.

ROSS B. HOFFMANN leaves next week for London and St. Petersburg.

H. ABBOT TITCOMB has returned to London from Newton, Massachusetts.

JAMES KIRK is assistant manager for the Greene-Cananea Copper Company.

POPE YEATMAN has been at the mines of the Braden Copper Co., in Chile.

CHARLES E. BROWN, of Seward, Alaska, is at the Palace hotel, San Francisco.

ALEXANDER LEGGAT, of Butte, Montana, is temporarily in Yuma county, Arizona.

FERGUS L. ALLEN is general manager for the Mexican Mines of El Oro, Mexico.

H. C. WILMOT was in San Francisco last week, on his way to Rye Valley, Oregon.

W. B. and J. H. DEVEREUX, of New York, were in the Hostotipaquillo district, Jalisco, Mexico, last month.

H. F. REID is to deliver the Hitchcock lectures at the University of California this spring, probably in the latter part of March.

A. ROY HEISE has charge of the new Avila refinery for the Union Oil Company of California, at Avila, San Luis Obispo county, California.

OSCAR LACHMUND, formerly at Denver and Salt Lake, is general manager for Cia. Minera de Durazno-Tetamoa, at Alamos, Sonora, Mexico.

CECIL POCOCK, formerly with the Montezuma Mines of Costa Rica, has been appointed chief engineer for the Cerro de Pasco Mining Co., at Cerro de Pasco, Peru.

W. H. ALDRIDGE has opened an office at 603 Central building, Los Angeles, in connection with the Gunn-Thompson properties, comprising the Inspiration, Mason Valley, and Magma, and the Gunn-Quealy Coal Company.

COPPER PRODUCERS' ASSOCIATION REPORT

Stocks of copper on hand in the United States on March 1 showed on increase of 14,198,280 lb. over February 1. The increase in stocks was despite a decrease in the production for the month of February of more than 3,800,000 lb. Domestic deliveries for February exceeded those of the previous month by over 8,000,000 lb., but foreign demand fell off almost as much. Total deliveries for February aggregated 95,630,000 lb., a nominal increase over January. The detailed statement follows: Stocks of marketable copper of all kinds on hand at all points in the United States, February 1, 142,439,490 lb.; production of marketable copper in the United States from all domestic and foreign sources during February, 109,828,297; deliveries of marketable copper during February for domestic consumption, 50,518,998, and for export, 45,111,019, a total of 95,630,017; stock of marketable copper of all kinds on hand in the United States March 1 were 156,657,777 pounds.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

SALE OR OPTION CONTRACT OF MINE

A contract recited that one, Reed, was the owner of a mine, and that one, Hickey, and his associates, desired an option to purchase it for an agreed price of $36,000, with a 60-day privilege in which to prospect by sinking a shaft at a certain point; that Reed agreed to sell and convey the mine to the other parties at any time within 60 days on the following payments and conditions: a payment of $10,000 on or before 60 days after date, and other payments to make up the price within the year following. The contract provided that all pay-gravel taken out by the purchasers during the 60-day option should belong to Reed, as well as all improvements placed on the premises during the 60 days for prospecting, on failure of the purchasers to make the first payment. The contract also provided that on payment of the first installment within 60 days, Reed would execute and deposit a deed in escrow to be delivered on payment of the balance of the purchase money, but to be returned to him on failure to make any of the payments, or violation of the conditions of the agreement; that on receipt of the first payment Reed would turn over to the purchasers the property and all apparatus owned and used by him in working the mine and the purchasers should then have the right of operating the mine for their own benefit. It also provided that a default in payment of an installment at the stated time, or a default in other matters stipulated to be done by the purchaser, should at once abrogate the agreement and the seller should re-enter and take possession of the mine and all improvements made or placed thereon, and all payments made should be forfeited to Reed as liquidated damages for the use and occupation of the property. In an action by Reed to recover the unpaid installments of the contract price, the purchasers contended that the contract was no more than a continuing option which was renewed as each payment was made and continued until the next payment. But in considering the contract, the court said in substance, that by its terms the option was limited to 60 days, during which time the vendees had the right only to prospect the mine at a particular point, but any gold taken out belonged to the vendors; but when the vendees became satisfied, they preferred to work the mine for profit rather than be confined to prospecting, and accordingly changed their attitude as prospectors and became operators and workers of the mine; they ceased prospecting at the point designated and announced their intention to purchase and paid their first installment a month before it was due, after requiring the vendor to cease mining and to surrender full possession to them with the privilege of retaining all the gold mined by them, which is shown to be $20,000 up to the time the second payment became due. It is unreasonable, the court suggests, to suppose that the vendor intended to permit them to appropriate all the gold they might mine and yet not be required to make the payment agreed upon. Under a supplementary agreement, which was shown to have been made and pursuant to the delivery of the deed in escrow, the vendees, under their construction of the contract, could have decided on September 28 not to take the mine, and could have retained the $20,000 taken out without making a second payment. But the contract does not warrant such a construction. The supplementary agreement refers to the payment as to be made upon the 'purchase price,' and provides that if the vendors fail to remove the encumbrances by a stated time the vendees need not pay the second installment, or any future installments of the purchase price until the property is clear of all encumbrances. This raises a strong implication that the vendees, on the construction of the contract by the parties themselves, were obligated to pay the installments as they become due if the title was made clear, and they so acted when the second installment fell due. Before 60 days expired it appears that the vendees availed themselves of the right to purchase, and not merely as optionees with a continuing right to buy, or not to buy, as they might elect. The court accordingly held that the contract was not a continuing option renewed as each payment was made, and continuing until the next payment, but on the first payment being made the option agreement became an absolute contract of sale.

Reed *v.* Hickey, (Cal.) 109 Pac. 38. April 1910.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

AMERICAN CIVIL ENGINEER'S POCKET BOOK. 4½ by 7 in. Pp. 1380. Ill. Flexible back. John Wiley & Sons, New York, 1911. For sale by *Mining and Scientific Press.* Price $5.

This pocket book has been built to order according to the very careful specifications of Mansfield Merriam. In the work he has had the assistance of a dozen of the best civil engineers in America and the result is a book of unusual excellence and usefulness. The contents include: Mathematical Tables, by Mansfield Merriam; Surveying, Geodesy, and Railroad Location, by Charles B. Breed; Roads and Railroads, by W. L. Webb; Materials of Construction, by Rudolph P. Miller; Plain and Reinforced Concrete, by F. E. Turneaure; Masonry, Foundations, Earthwork, by I. O. Baker; Masonry and Timber Structures, by W. J. Douglas; Steel Structures, by F. P. McKibben; Hydraulics, Pumping, Water-Power, by G. S. Williams; Water-Supply, Sewerage, Irrigation, by Allen Hazen; Dams, Aqueducts, Canals, Shafts, and Tunnels, by Alfred Noble and S. H. Woodward; Mathematics and Mechanics, by E. R. Maurer; Physics, Meteorology, Weights and Measures, by L. A. Fischer.

THE MINING MANUAL, 1911. By Walter R. Skinner. 8 vo. Pp. 1372. Maps, index. London, 1911. For sale in the United States by the *Mining and Scientific Press.* Copies may be seen at 29 Broadway, New York, and 667 Howard street, San Francisco. Price $5.25.

The promptness with which this indispensable handbook is issued this year is especially commendable. This promptness has been secured by thorough preparation rather than by sacrifice of pertinent data. Indeed, the Manual, which in the quarter of a century since the first edition was issued has grown mightily, now includes details regarding 5300 companies. British mining operations are world wide, and while therefore only English companies are discussed, there is valuable information regarding gold and silver mining in every country. In no other place can the same data regarding companies and mines be found. All firms attempting to do business abroad, and all engineers interested in gold mining will find the book extremely valuable.

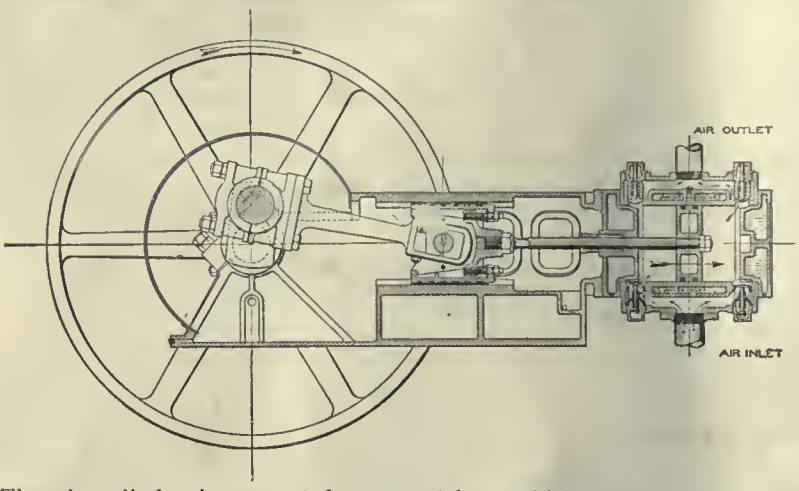
PRACTICAL MINERALOGY SIMPLIFIED. By J. P. Rowe. 5 by 7¼ in. Pp. 162. John Wiley, New York, 1911. For sale by *Mining and Scientific Press.* Price $1.25.

This book has been written in simple language and is designed for the use of miners and prospectors rather than trained mineralogists. It is an excellent and useful publication despite certain minor errors, such as the statement that blende is extensively mined in Pennsylvania, which is no longer true, and the omission of New Mexico and inclusion of Missouri in listing States in which smithsonite is most abundant. For the main purpose, however, that of assisting in the prompt recognition of the common minerals, the book is well designed and well executed.

WEST VIRGINIA GEOLOGICAL SURVEY, BULLETIN II. I. C. White, State Geologist. Pp. 385. Tables and index. Morgantown, 1910. Part I of this bulletin is a general table of elevations in West Virginia. Part II is a complete table of analyses of the coals of West Virginia, taken in order from the oldest to the youngest, including some new determinations. It is accompanied by a map of Wood, Ritchie, and Pleasants counties, showing the oil and gasfields.

SMALL AIR-COMPRESSORS FOR HEAVY DUTY

The accompanying illustration shows a new single-stage steam and power-driven Sullivan air-compressor, recently placed upon the market. The new compressors have been designed especially for mining work. Air-power service demands above all else, continuous and reliable performance. Troubles with the compressor mean idle tools and idle men, causing waste which soon evens up the difference in the purchase price between a good air-compressor and a poor one. The air-compressors here described are of small to moderate capacity and are built for various pressures running from 10 to 100 lb. per square inch. These compressors consist of a heavy substantial frame, supporting the bearings and crank-shaft at one end and the steam and air cylinders at the other. The machines are of the centre-crank type and a heavy steel guard surrounds the crank and prevents oil from being thrown upon the floor. In the steam-driven machines, the plain steam slide valve is controlled by an eccentric on the shaft, with which it is connected by a simple but satisfactory arrangement of valve rods. The air cylinder is placed outside the steam cylinder, and is connected to it by a heavy distance piece.



The air cylinder is supported on a sub-base which runs the entire length of the compressor, and maintains proper alignment of all the parts. In the belt-driven machines, the air cylinder is attached directly to the rear end of the frame, and all the working parts, such as the crank-shaft, cross-head, connecting rods, and main bearings are of dimensions and contain an amount and quality of material which provide a factor of safety much higher than is considered necessary in standard compressors of much larger size. All parts liable to wear are arranged so that wear may be taken up fully and with the least possible trouble, so that even after these machines have been in service for years, all their working parts remain accurately aligned and in condition to operate with practically their original efficiency. Particular attention is directed by the builders to the design of the air cylinder; it is cored to form water jackets, and the cylinder heads are also jacketed over their whole surface. This feature keeps the heat generated by compression within safe limits. The air-valve mechanism consists of radial automatic poppet valves for both inlet and discharge. These valves are placed close to the ends of the cylinder, the inlet valves being at the bottom and the discharge valves at the top of the cylinder. These valves act in a true radial direction to the axis of the cylinder, and reduce to the lowest terms the losses in efficiency made necessary by clearance. The ports or pockets leading to the valves are short and direct so that practically no air is trapped after compression. The valves and their parts are so made that in case of breakage it is impossible for the broken pieces to enter the bore of the cylinder. The valves are held in place in cages, which seat, by means of taper fits, in the cylinder walls. To remove these valves it is only necessary to unscrew the plug on the outside of the cylinder, when the entire valve and cage may be withdrawn for inspection or re-grinding. The main bearings have adjustable caps and are heavily lined with a good grade of babbitt metal. They are bored out at right angles to the centre line of the piston rod by a special fixture which assures accurate alignment. A box pattern cross-head is used, being the same type as that employed in cross-compound machines of the highest grade. It is fitted with adjustable shoes and is regarded as unexcelled in wearing qualities and ease of adjustment. The steam machines are governed by a split-ball throttling regulator with an extra cylinder which places the throttle valve under the influence of the air-receiver pressure. The power-driven machines are fitted, when desired, with an unloading device placed on the air inlet of the compressor. This device is set to shut off the incoming air to the compressor when the receiver pressure exceeds a pre-determined point.

SULPHURIC ACID HANDLED BY COMPRESSED AIR

In the manufacture of certain chemicals considerable danger and expense is caused by the rapid deterioration of piping and other receptacles with which the acids and fumes come in contact. Sulphuric acid is particularly destructive, and many serious difficulties are encountered in its manufacture. It is practically impossible to handle sulphuric acid with pumps, as they would deteriorate so rapidly that constant replacement would be necessary. A satisfactory method of pumping destructive acids is that used at the Nichol Syndicate's new plant at Bay Point, California. At one stage of the process of manufacture, the acid is accumulated in a cylindrical tank which is provided with suitable inlet and outlet valves. When it is desired to pump the acid into other retainers, the inlet valve is closed and air at from 60 to 100 lb. is admitted, which forces the liquid through the outlet valve to other parts of the plant. The flow of the acid is controlled by suitable valves in the piping system. To meet the increasing demand for apparatus that will handle destructive acids economically, the United Iron Works of Oakland, California, has built a motor-driven compressor unit. The compressor is a 6 by 6 Gardner-Rix Duplex; speed 200 r.p.m., pressure 60 to 100 lb., capacity 40 cu. ft. of air per minute. The compressor is driven by a Westinghouse type HF 3-phase, 60-cycle, 550-volt motor rated at 10 hp., 860 r.p.m. This type of motor is admirably suited to this work. The secondary is phase wound and the three phases are connected to the three collector rings shown. In starting, the controller gradually cuts out the starting resistance which is connected to the secondary through the collector rings. This motor is so designed that an unusually high starting torque is developed, with comparatively low starting current.

TABLE OF CONTENTS

EDITORIAL

INJUNCTION against the further operation of the Washoe smelter has been denied in the F. J. Bliss case, by the United States Circuit Court of Appeals, which thereby sustained the lower court.

ELECTRIC SMELTING of copper ores is one of the possibilities in California, where the process is already applied to iron-making at Heroult in Shasta county. An experimental plant for copper smelting is being built at Delamar.

VOTES of shareholders in the various companies proposed to be consolidated with the Calumet & Hecla Company indicate that, except among Osceola stockholders, the move has the endorsement of 70 to 90 per cent of those concerned.

THE Cia. Metalúrgica y Refinadora del Pacífic, S. A., has shipped from Guaymas to the Mountain Copper Company's smelter, near San Francisco, about 5000 tons of its excess silicious ores, and at the same time is a purchaser of basic constituents. So the international chemical balance is maintained. This is the largest ore shipment ever made from a Mexican Pacific port.

THE second annual edition of 'The Mogollon Mines' contains well written and well illustrated accounts of the principal mines in the southwestern part of Socorro county, New Mexico. This interesting region, in which gold and silver were discovered in 1876, has lately attracted renewed attention. A new road from Silver City, completed with funds furnished by the Forest Service, materially shortens the distance and increases the accessibility of the district.

CALIFORNIA corporations have been asked to make complete returns to the State Board of Equalization, and a tax on the 'franchise' of each corporation impends. This is an unforseen result of the Constitutional amendment adopted last fall, and while the tax will doubtless be small, it has disturbing possibilities of growth. Mining corporations that have not yet reached a productive basis are in a particularly vulnerable position and the new rule may force a number to disincorporate; a step already taken by a number of small mercantile companies. This would hamper development, though there would be some compensation if it brought about a revival of the old system of prospecting partnerships. Much work would be stopped, but if each investor had to accept a partner's liability he would pay closer attention to the business.

IMPORTANT changes in treatment of Butte ore at Anaconda and Great Falls, Montana, are now reported to be under consideration. The concentration methods employed at the mills of the Utah Copper Company have recently been studied by engineers and officials of the Anaconda company, and it is said that attempts will be made to increase capacity by introducing roughing-tables and other features of the Utah practice.

COPPER in Russia is attracting attention now, and American engineers are prominent in developing the deposits. We recently printed a brief note from Mr. S. H. Ball, who lately examined the Kyshtim deposits. Mr. R. Gilman Brown is in charge of these important mines, and Mr. H. W. Turner is now on the ground. Mr. W. G. Perkins has returned to London, having started the new smelter, which is reported to be doing satisfactory work with 1¼ per cent coke on the charge, which is excellent, though not the record for pyrite smelting.

THE UNITED STATES SUPREME COURT has, by unanimous decision, upheld the corporation tax provision of the tariff act. This renders a corporation subject to a one per cent tax upon its net income. It had been contended that such an impost was a direct tax, which is forbidden in the Constitution. The Court maintained that it is an excise upon the privilege of carrying on business under corporate rights and exemptions and, as such, entirely constitutional. When the National Government begins to examine the accounts of corporations to determine their net incomes, some interesting disclosures should result.

A FRIEND, not in the engineering profession, who has just returned from a long journey, writes us this pleasant assurance that a good opinion of the mining profession is not confined to its own ranks. "Coming from a country where in some professions, at least, the words 'professional courtesy' have not become trite from excessive use, it was delightful to see the sincere regard which mining men everywhere have for each other's interests. Self-interest and convenience seemed of no account if it was possible to aid a fellow mining engineer, while time, such a valuable commodity to the business man, was so courteously ignored. It made one believe that men in the mining professions are, as you remarked in a recent editorial paragraph, indeed 'bred in the deep purple'."

RECENT events in the Far East are not surprising, since they develop so naturally out of the Russo-Japanese *entente cordiale*. Trial and compromise is a recognized method in philosophy. Russia and Japan once met in a trial of strength to determine which should dominate the northern portion of the Chinese Empire, but now have philosophically agreed to compromise and divide it between them, if possible. Act I was the occupation and annexation of Korea, the building of military railroads in Manchuria in the face of Chinese protests, and the veiled and gradual attempts at usurpation of governmental functions in Manchuria. Act II is the movement of troops to the Mongolian border to enforce the demand for special privilege in that territory. What will be the third act in this Far Eastern drama? Has the most powerful nation on the Pacific no interests that are involved in the significant political events that have succeeded one another with such astonishing rapidity on its farther shore? The time for action is before it is too late.

The Mexican Situation

Concentration of a large force of American troops along the Mexican border has given rise to many rumors and much uneasiness, both north and south of the line. That the situation in the southern Republic is serious has been known for some time to mining men, as well as others who have kept in touch. Democracy has felt the pains of growth. The great progress that Mexico has made in the last half century has been a matter of pride to all familiar with the country and its people. The change from the old Mexico to the new has been fundamental and comprehensive. It has involved legal and social institutions as important as the more generally recognized industrial and commercial changes. That [illegible] has been accomplished with so little friction speaks volumes for the people as well as the leaders. Complete evolution, however, is never accomplished without pain; and from the Mexico of great *haciendas*, a feudal community of home industries, to the Mexico of tomorrow, an industrial democracy, is a complete cycle of evolution. The marvel is that so much has been accomplished so quietly. We have frequently expressed our high opinion of the one man to whom more than any other, this accomplishment has been due—Porfiro Diaz, president of the Republic of Mexico. We yield to none in our appreciation of his great service to his country and to the world; but there comes to each man a time when his particular work is accomplished, when another can take up the burden to the betterment of the result. Many have expressed the belief that that time has come to Porfiro Diaz. Had he on the celebration of the centenary of the Republic laid down his public burden, a grateful country would always have acclaimed him as he deserves. The moment, however, passed, and a revolution started November 20. The fighting since that date has been inconsequential; the movement is even yet thoroughly serious only in its potentialities. The Mexican Government, lulled into security by years of peace, had reduced the military establishment to a relatively small army. The sudden appearance of bands of *insurrectos* at many points has created a situation that is temporarily, at least, beyond the power of the Mexican officials to control. It must not be forgotten that one small but active band of men may keep a large force exceedingly busy, as was abundantly shown in the campaigns between the Cubans and the Spaniards. A few Apache Indians disturbed the whole Southwest for years, despite the presence of a much larger number of United States soldiers throughout the region. In Mexico the warfare has been so far of the guerrilla type. To the

mining industry the principal damage has been that incidental to the breaking up of ordinary lines of communication and transportation. In Chihuahua the situation in this particular has been undeniably bad for weeks. The Mexican Northwestern has been practically put out of service and it is not surprising that the Canadians are said to have made strong representations as to the need of protection for their properties. Foreign interests in Mexico, especially in mines and railways, are large. It is natural that security holders in the United States and abroad have become restless as the weeks have passed and neither the Federal forces nor the *insurrectos* seemed to be making permanent headway. Everyone, Americans most of all, concedes the right of Mexicans to determine their own form of government and to do it as they may see fit. We have a deep-rooted prejudice in favor of the established government; a feeling that rests on its long record for fairness and ability. If, however, the Mexican people want to change by revolution or otherwise, that is their business, not ours. The United States, it happens, has been made a vantage-ground from which a certain type of trouble-maker has operated in fomenting the [illegible]. There has been serious danger more than [illegible] during the last year, of 'Jamison raids' and a project to establish an independent State in Lower California and to apply for admission to the United States, have been freely discussed at Los Angeles. The international border-line forms an ideal place for filibusters and guerrillas, since the Rio Grande can be crossed with ease at almost any point, and, once crossed, the bandits are safe from immediate pursuit; as useful a privilege as the ancient right of sanctuary to the robber knight. To furnish such an asset to the enemies of the Mexican Republic is scarcely the act of a friend. Instead a cordon of troops along the frontier [illegible] at once aid and an earnest of good-will. That there are political questions of a serious nature demanding public attention in Mexico, no one would attempt to deny. Few nations are fortunate enough to have completely solved their great national problems in this century of rapid change and growth. But such problems call for the attention of the serious-minded; sansculottism can produce no other result than political chaos.

It is not to be denied that the force that has been sent South is larger than would be needed if guarding the border only was in view, and therein lies the ground for surmise. There can be little doubt that, whatever the cause, the General Staff has welcomed the occasion for undertaking the maneuver. In view of the frequent criticism of the American Army and the bad record made by the transport and commissary department in the Spanish War, it is not surprising that the general officers are delighted at a chance to show off. The new organization, for which Mr. Elihu Root is mainly to be thanked, has worked with a quiet efficiency that begets great confidence. Troop-ships out of commission in Norfolk harbor on Tuesday sailed, newly painted, fully provisioned, and loaded with soldiers, on Thursday, and other achievements of like order were in evidence plentifully. There are doubtless those in Washington who have taken pains to see that these items were duly reported to representatives of foreign governments supposed to be interested. In the main, we believe the movement has been a somewhat theatrical trying-out of a new organization; akin to the practice run of a new fire engine in a country village.

The international political credit of the United States is fundamentally involved in the maintenance of law and order within the Mexican border. The principle that European nations must not acquire territory in Latin-America carries with it as a correlative the responsibility of the United States to European nations for the protection of European interests in our hemisphere. European interests in Mexico are reckoned in the hundreds of millions of dollars, and a request from European powers for the United States to be more diligent in the performance of her international obligations would be as unpleasant as it should be unnecessary. With the aid of a strict policing of her guerrilla-infested northern border, Mexico should soon be able to restore stable conditions throughout her territory.

Avalanches

Snowslides in the Sierra Nevada, California, the Wasatch mountains of Utah, and in the San Juan country, Colorado, have wrought destruction to life and property during the last few weeks. The avalanches last week in Mono county, California, destroyed the power plant of the California Hydro-Electric Company at Jordan, damaged that of the Crystal Lake Power Company, and killed ten or twelve persons at Jordan, Crystal Lake, and Masonic. The loss of life and damage to mining property in Utah was noted in our news columns recently. The latest fatalities in the San Juan occurred on March 12, when the boarding-house at the Gold King mine, near Silverton, was swept away, and four men were killed. The destruction and damage to the power-plants near Bodie will retard to some extent mining and milling operations in Mono county and in some of the camps of Nevada, although it is reported that in Nevada connection can be made with transmission lines of other systems so that electric energy for light and power can be obtained. Snowslides occur in regions having precipitous mountain slopes, where the snowfall is heavy, and when the temperature is such as to cause a slight thaw. The compression of the snow gives it the hardness and density of ice, and the momentum the avalanche acquires in a movement of 2000 to 3000 feet on a slope of 45 to 70°, develops almost irresistible energy. Trees and deeply imbedded rocks are swept away, and structures built by man are demolished. To be caught in a body of compressed snow under such conditions is like being encased in solid ice. Slides may be divided and dispersed by deflecting barriers; but one difficulty is that they are likely to occur in new places, so that it is easier to think of escaping from them than of any means of resistance.

Cobalt District, Ontario

By S. F. Emmons

*Doubtless most of you are more or less familiar with the general geological relations of the Cobalt district as given by the Canadian geologists. My own examination of the district has been too brief and cursory to justify any criticism of their determinations, which I therefore accept as far as the areal geology is concerned. The ore deposits are, however, of so remarkable a nature and so utterly different from anything seen within the boundaries of the United States that I have thought it might be interesting to you to hear what particularly impressed one who has had considerable experience in the study of the latter. I will begin with a brief statement of the facts thus far determined by the Canadian geologists, since some of you may not have had occasion to inform yourself with regard to them.

The Cobalt district lies in the rugged region known as the Archean protaxis, about 330 miles due north of Toronto, midway between Lake Ontario and Hudson Bay. Rich ores were first discovered in the district in 1903, as the result of the building of the Government railroad, known as the Temiskaming & Northern Ontario, northward from North Bay on the Canadian Pacific railway. Yet the district is on an old traveled route, and an argentiferous galena deposit had been worked on the shores of Lake Temiskaming, eight or nine miles to the eastward, over 160 years ago, and which shows how readily valuable deposits of the precious metals may escape observation.

Two geological maps are published by the Department of Mines of Ontario, the smaller, the Temiskaming sheet, covering an area of 15 miles square, on a scale of a mile to the inch, with Lake Temiskaming in the eastern half, and the Cobalt district a little south of the centre. The larger represents the Cobalt district on a scale of 400 ft. to the inch, with a contour interval of 10 ft. The geological colors on these maps represent the following formations, commencing with the older:

Keewatin is the oldest pre-Cambrian formation, and consists of an igneous complex, largely altered diabase and basic tuffs, intruded by granite, in the southwest portion of the area.

Lower Huronian.—Unconformably on these lie the Lower Huronian rocks, consisting of conglomerates and graywacke (slate or altered quartzite), which contain fragments of the older series. These are separated by another unconformity from the next higher.

Middle Huronian.—A series of arkoses (or 'green quartzites') with conglomerates and quartzite, which rest unconformably on the preceding.

Diabase.—All the above mentioned rocks are cut by intrusive diabases which are hence assumed to be of pre-Cambrian age. A great unconformity, representing a long period of erosion, separates the preceding rock from the succeeding rocks.

Niagara limestone, which is found on the shores and islands of Lake Temiskaming. The area is one of many patches of Paleozoic rocks that seem to have escaped erosion, because of being included in a synclinal depression of the ancient surface.

The more common minerals of the rich vein deposits are the arsenides of cobalt and nickel, smaltite with some chloanthite, cobaltite, and niccolite, associated with native silver. Less frequent are native bismuth, the silver minerals pyrargyrite, proustite, dyserasite, and argentite, the nickel sulphide, millerite, with occasional mispickel and tetrahedrite. The ordinary sulphides, pyrite, galena, and zincblende, are occasionally found in the wall rocks, but apparently do not form an essential part of the deposits. The gangue minerals are calcite with a little quartz, but both are in relatively subordinate amount in the rich parts of the veins. Minute calcite veins are common throughout the rocks of the district and often serve as leaders which are followed in searching for pay-ore. On the surface the cobalt veins are traced by the delicate pale reddish-blue color of 'cobalt bloom' (the hydrous arsenate of cobalt) which is the oxidation product of the cobalt minerals.

The veins in which these minerals are found are remarkably narrow, being from one or two inches up to eight inches in width, and in exceptional cases more than a foot for short distances. They are generally nearly vertical, but seem to be rather irregular in strike. In some cases the pay portions bend almost at right angles: in such cases as came under my observation this was caused by the mineral leaving a fissure of a given strike to follow one running in another direction, the first fissure continuing on, though barren of ore. The linear extent of the pay portions of the veins is not great, generally not over a few hundred feet, but the actual extent of the fissure is evidently much greater. How much could not be determined, as they are often simple lines of barren calcite, which are not followed for any great distance. In depth it was soon found that the very rich ore, which carries from 2000 to 6000 oz. per ton, does not extend, as a rule, more than 200 ft. in depth, often not as much, and the first generalization of the Canadian geologists was that the Lower Huronian conglomerate is the favorite *habitat* of the rich silver ores, and that they cease when the vein reaches the underlying Keewatin, which was explained as due to the physical character of the rocks of that formation, which do not fissure as readily as the Huronian. As prospecting was therefore mostly carried on in the rocks of this formation, a larger percentage of vein deposits has been discovered in it than in the other formations, but, as I shall show later, this does not seem at present to be the most probable explanation, an increasing number of pay-veins being found both in the diabase and in the Keewatin.

As to the origin of the fissures, the idea has been more or less prevalent that they are the result of contraction, because in many places they resemble joints, and show no slickensided surfaces. On the

*Read before the Geol. Soc., Washington, January 26, 1910.

other hand, it is recognized that they run continuously from the Huronian into the underlying Keewatin, which are separated by a great unconformity. On this point, W. G. Miller, the geologist of this region, after calling attention to the fact that the fragmental Huronian rocks have been less disturbed in the productive area than in the surrounding regions, says: "This left them in the right physical condition to be readily jointed and fissured by the contraction of the diabase." As to the genesis of the minerals, they have been assumed in a general way to have been connected with the post-Huronian diabase eruption. There are said to be diabases of several ages from Keewatin to probable Keweenawan. The post-Huronian diabase carries

North-South No. 7 Vein; 90-Ft. Level; 12 Inches Wide; Kerr Lake Mine.

some quartz. Miller says: "After the deposition of the cobalt-nickel arsenides, the veins appear to have been slightly disturbed, giving rise to cracks and openings in which the silver and later minerals were deposited. Veins which escaped this later slight disturbance contain little or no silver." A granite or aplite dike cutting diabase is found within the Cobalt area, on the north shore of Giroux lake, on the University claim, and outside this area aplite is more frequent in similar association, and is said to carry cobalt, whence it has been assumed that the aplite, which constituted the last phase of the diabase eruption, was the mineral carrier. C. R. Van Hise considers that the diabase body in the Cobalt area is in thin sills and hence does not extend deep; basing his assumption on the fact that the rocky beds that it intrudes are not upturned or pushed back, but comparatively undisturbed. This assumption has been in a measure confirmed by the finding, either by shaft-sinking or drill-holes, of underlying rocks at one or two points within a few hundred feet of the surface. It is generally recognized that the native silver is of distinctly later deposition than the cobalt-nickel arsenides—indeed, the evidence in the mines is most conclusive. In one case I observed a distinct narrow vein carrying native silver and calcite that crossed the mass of cobalt ore at a slight angle. Very often minute cracks may be seen crossing the cobalt mineral and gangue rock which are filled with films of native silver, and the flake or sheet form in which the silver is so often found, shows that it has grown in such cracks. That, however, the silver, as a whole,

Macdonald Vein; 150-Ft. Level; in Bend of North Drift; Very Wide; Kerr Lake Mine.

is of a distinctly later period of deposition, as seems to have been assumed, I am inclined to doubt. At any rate, it does not appear to be, as yet, definitely proved.

My own visits to the district in the past year have been too brief to admit of an exhaustive study, though I was able to see one mine pretty thoroughly and visit one or two others, so that what I have to say is rather tentative than final. The early mining, owing to the novel character of the deposits and the want of experience of most of those in charge of mines, was not very systematic, being largely in the nature of trenching on the surface and digging out the rich ore immediately in sight. Systematic exploration by underground driving and cross-cutting is a comparatively recent feature of the work. I was, however, fortunate in visiting a mine that had been developed by an engineer of long practical experience in managing large mines

in Colorado, in which the facilities for underground study were in consequence exceptionally good. This is the Kerr Lake mine, which occupies a tract of 57 acres, part of which is under the lake. In spite of the relatively small area of the property, this mine has proved one of the most productive of the district, having thus far developed five remunerative veins, to say nothing of a host of small veins, as yet of no great producing capacity, but which may any day develop pay-shoots. Singularly enough, the largest orebodies, with one exception, thus far developed have been under the waters of the lake, which is also the case with the adjoining Crown Reserve mine. This fact has led some of the mining men to think there is some genetic cause which renders the ground under the bottoms of the many lakes that dot the region peculiarly favorable for the concentration of rich ore, and the rights to mine under these lakes have been purchased from the Government at very high prices in one instance, I believe, for over a million dollars.

The exceptional character of mining in this district, and the favorable results of a good system may be shown by extracts from the annual report of operations of this mine for the year ending August 30, 1909. The gross product for the year was 2,668,648 oz. of silver from shipments of 1072 tons of ore and 300 tons of screenings (an average of 2489 oz. per ton), and the net profits $1,129,047, of which $480,000 had been paid out in dividends, and over half a million held in reserve as an exploration fund. The aggregate length of driving and shaft-sinking during the year was over a mile and a quarter, the principle laid down by the directors being to open up two tons of ore for every ton taken out. Another particular in which the system of work in this mine differs from that of most of the other large mines, is that by careful handling and sorting, only very rich ore is produced, which is sacked, and the necessity of large concentrating mills to treat second-class ore (that is, ore running less than 100 oz. per ton) is obviated. I would say with regard to the Kerr Lake mine that since the close of the fiscal year several important new finds have been made, and the present rate of dividend is double that of the previous year.

One object of my visit was of a commercial nature, that is, to form an idea of the probable permanence of the camp as a whole. A power company had been formed to furnish compressed air from a central hydraulic power-plant to the mines of the entire district. Such a plant is of the utmost economic importance, because all the rocks are so hard that it is impracticable to mine without the use of machine-drills, but power is very expensive, owing to the high price of coal and the uncertainty of its supply, due to the frequent congestion of traffic on the single line of railroad that serves in the district. One naturally feels doubtful about the persistence of such extremely rich ores as are found there, the mines forming an extreme type of what in the West are denominated 'specimen mines.' Moreover, it is generally admitted, even among mine-owners, that the bonanza portion of the veins almost never extends more than 200 feet in depth. Evidently the installation of a power plant, however favorable the conditions today, would not be a desirable investment if the mines are likely to be exhausted in two or three years. The only offset to the want of persistence in depth would be the multiplicity of veins that might exist, so that with increased facilities for working it would be reasonable to expect that a constantly increasing number of productive veins would be opened.

There has appeared recently in the Journal of the Canadian Mining Institute a paper by G. R. Mickle on 'The Probable Number of Productive Veins in the Cobalt District', which bears upon just this point. The facts upon which he bases his deductions, however, were gathered prior to July 1907, and hence do not include two and a half years of the most energetic work. He estimates that in the productive area of under 10 square miles there are 2000 to 2500 veins, of which 90% are calcite veins quite barren of metallic minerals; 10% contain only occasional small amounts of metallic sulphides and a fraction of an ounce of silver per ton, and probably less than 1% are productive silver veins. This estimate was based on examination of certain tracts, not in the most productive area, that had been reduced in area because of the want of discovery of actual mineral. He then proceeds to count the actually developed veins, distribute them among the calculated areas of the three formations, Huronian, diabase, and Keewatin, and to compare them with the long-worked European districts where somewhat similar ones are found, Annaberg and Schneeberg in Saxony. I shall not go into details of his estimates, because the comparisons will soon lose their force when the Cobalt district is systematically prospected. Thus his estimate of 66 productive veins for the Cobalt district had, he admits, been increased to 84 by July 1909, and the preponderance of those he gives for the Huronian, being 53, to 6 in the Keewatin and 7 in the diabase, might be, in part at least, due to the more vigorous prospecting in that formation, as a result of the geological deductions of the Canadian geologists. He finds that in the Annaberg district of 21 square miles, there were about 200 productive veins, or 0.6 of a vein to a claim of 40 acres; and in Schneeberg, with an area of 3.8 square miles, 150 veins were found, or 2.5 veins per claim.

In my examination of the district, what particularly impressed me, besides the exceptional richness of the ore, was the peculiar character of the rocks as a whole, and of the fissuring of these rocks. The impression produced was that the phenomena were immensely old and had been produced under unusually great pressure. All the rocks are extremely dense and hard. It is not simply that they show evidence of great regional metamorphism, for metamorphosed rocks may be rather loose-textured, but they are peculiarly close-grained, and have grown to have a general resemblance to each other, so that in hand specimens the Keewatin rocks, and the intrusive diabase are scarcely to be distinguished from each other or in some cases from the Huronian

graywacke. The typical Huronian conglomerate in the vicinity of the town of Cobalt carries rather large and generally angular fragments of granite and other rocks that do not outcrop in the neighborhood, in a fine-grained matrix of more or less fragmental material, which might have been morainal, whereas what is called conglomerate in the Kerr Lake vicinity is a band of dark, homogeneous-looking rock, like an indurated mud, in which are rounded pebbles of similar material, the whole looking like a hardened boulder till. It seems that the suggestion of a possible glacial origin for some of these rocks has already been made, but the absence of a boulder till was one of the grounds on which it was rejected. In the Kerr Lake mine this lies between the dark greenish-gray Huronian graywacke, or altered quartzite, and the underlying Keewatin, but it is difficult to find any sharp dividing line between the two formations. The true conglomerate is supposed to overlie the graywacke, but I did not find the full series present at any one place. At the Kerr Lake mine these two formations, the Keewatin and Huronian, dipping gently northward under the lake, occupy the northern half of the claim, the rest of the area being covered by diabase, which also bounds the Huronian on the north. Its relations were not ascertained, it having been found impracticable to trace the contact between diabase and Keewatin.

No. 7 Vein (East-West) 150-Level; Several Thin Parallel Veins. Kerr Lake Mine.

That the ore-bearing fissures are true rock fractures or faults of slight displacement I feel quite certain. They contain in the wider parts broken-off fragments of the adjoining country-rock, they pass continuously and without interruption from one formation into another, and in the conglomerates they cut across pebbles or matrix indifferently. Yet no gouge or slickensided surfaces could be detected, either in primary or secondary fractures, and in some cases they are continuous with cracks that resemble contraction joints in an eruptive mass. The great majority of the veins are thin cracks a fraction of an inch in width, filled with calcite; what the miner would designate as very tight seams. They are generally straight and quite barren of metallic minerals for considerable distances, and may pass into a series of parallel fractures, one of which will carry ore. In the case of important ore-shoots, they then pass into remarkably well defined veins 3 or 4 to 8 inches in width, carrying a solid mass of cobalt and nickel arsenides, more or less impregnated with native silver and with a rather subordinate amount of gangue, mostly calcite with which a little quartz is occasionally associated. At times even greater widths are attained. In such cases there generally seems to have been a structural cause for the widening, such as a crossing of one or more fractures, or some other deforming disturbance. It is difficult to determine whether these enlargements of the veins are due to the primary or secondary fracturing; for it is very evident, as Mr. Miller states, that there have been two periods of fracturing. In one instance I saw a vein carrying native silver and calcite less than an inch in width, crossing at a low angle a vein 4 to 6 inches in width filled with massive cobalt ore; but in most instances the secondary fractures are so minute as not to be distinguishable by the naked eye. That they do exist, however, is indicated by the frequent sheet form of the native silver; on one of the polished specimens I have, properly reflected light shows very distinctly the silver following minute cracks across both cobalt ore and gangue, or else following the outlines of a more or less crystalline mass of cobalt. In the one instance where I was able to observe the vein in depth, below the zone of secondary enrichment, it had identically the same characteristics as in the levels above, where instead of 10 oz. it carried several thousand ounces per ton. Indeed, the miners distinguish between pay and non-payable ore by its feel rather than by its appearance. The thin projecting sheets and points of silver give a peculiarly rough feeling that the unenriched ore does not possess; but the native silver is by no means always visible in hand specimens of rich ore. This again is well illustrated in the two polished specimens, which are from the No. 3 vein in diabase of the Kerr Lake mine; one the ordinary enriched silver which averages over 2000 oz. of silver to the ton; the other taken from the 350-ft. level only a few feet below the rich ore, which carries less than 10 oz. of silver. In this latter specimen, however, polishing has disclosed several little points of native silver scattered through the generally thin white mass of cobalt ore. The niccolite that is present is only distinguishable with a glass as faint copper-colored spots in the general white mass.

In some cases the ore passes from one fissure system to another that makes a decided angle with it, thus producing a crooked vein. A marked instance is the No. 7 vein of the Kerr Lake mine. From the

shaft the rich silver vein runs due north for several hundred feet, then bends sharply to the west. There are two systems of narrow calcite veins here, one running due north, the other nearly east and west. The No. 7 vein, as it is called, has thus far been traced 700 ft. in pay, that is, in ore that runs from 2000 to 4000 oz. The west branch has been traced to the west boundary of the claim, and is apparently a continuation of the famous Crown Reserve vein, which, like the No. 7 vein, is mainly worked beneath the waters of the lake. In tracing the No. 7 vein westward, another rich vein, the Macdonald, was struck, which runs northeasterly, and near the junction the No. 7 vein attains a width of 22 in. The vicinity of the junction of these two veins has evidently been a region of unusual disturbance. The veins there vary greatly in strike, are very irregular in width, less continuous than usual, yet as a whole they are exceptionally wide and very rich in silver. The narrow calcite vein which forms the normal continuation of the north-south portion of the No. 7 vein has been followed several hundred feet north without developing pay-ore. At 200 ft. north of where No. 7 vein bends to the west, an exploring drift has been driven eastward on an east-west calcite vein that for over 200 ft. was a mere line in the dark homogeneous graywacke; then it began to widen, and split into several parallel cracks, which after a little merged into a 4-in. calcite vein, and then suddenly, in a short distance, developed a 6-in. vein of 4000-oz. silver ore. A cross-vein running northwest, carrying silver in considerable amount, had already been cut by the exploring drift, about a hundred feet back.

The most regularly remunerative vein in the mine has been the No. 3 vein in the southeast corner of the claim. This is a north-south vein, nearly vertical, and averaging 2 to 4 inches in width. Its payshoot is 300 ft. long and has been followed to a depth of 350 ft., where the ore suddenly stopped. This is entirely in diabase, whereas the No. 7 vein is in Huronian graywacke. So far as developed it is remarkably straight, and there is no essential difference in character of fracturing in the diabase or the Huronian. As I have already said, I was particularly impressed with the close character of the fractures, in strong contrast with those we are accustomed to see in the Rocky Mountain region, where width is measured by more feet than these have inches. It may be that it is less close in the mines near the town of Cobalt, where the coarse conglomerates prevail and ore containing up to 50 oz. of silver is found in the wall rocks, so that mills have been built for concentrating such materials, but it is a difference rather of degree than of kind, as far as my observations went.

I could find no evidence that the silver had been introduced from below by a later accession of metal-bearing solutions, as seems to have been implied, if not explicitly stated, by those who have written on the subject, and I am inclined to believe that the second period of fracturing has served simply to furnish channels for descending silver solutions. I further believe that the reason that in the early veins the very rich ores did not extend far into the underlying Keewatin is to be found less in the fact that the Keewatin is unfavorable to the formation of fissures, than because the downward limit of secondary enrichment had been reached about at that depth. The change from rich to poor ore is certainly a remarkably abrupt one. In the No. 3 Kerr Lake mine, it occurs within 20 ft. or so, and in the No. 7 vein at the shaft it has been said that within two feet the ore dropped from 2000 to 20 oz. The depth at which this change takes place is extremely variable. There are cases in which it has occurred within a few feet of the surface, and as already stated in the No. 3 Kerr Lake vein it is at a depth of over 300 ft. That denser, more plastic rocks may have an unfavorable influence, since in them there is less likelihood of cracks that are sufficiently open to admit the descending solutions, is quite probable, but there does not seem to be any general association of this condition with the bottoming of the bonanzas. I have in mind a single case. In the north-south portion of the No. 7 Kerr Lake vein, the bonanza seemed to stop at a band of dense black indurated slate which dips northward with the other sedimentary formations, but is above the so-called Huronian conglomerate, already spoken of as resembling a tillite. In the northwestern part of the claim, however, where this slate band has not been distinctly recognized, the bonanza has already gone down 50 ft. below the horizon the slate should occupy, and has reached a depth of 190 ft., whereas at the shaft it stopped within 100 ft. of the surface. At other points observed there seemed to be no change of rock associated with the bottoming of the bonanza zone. The microscopic study of polished specimens of the same vein in and below the bonanza discloses, as the main difference, the absence in the latter of the minute cracks traversing the vein material that characterize the former, and that evidently have served as channels for the introduction of the silver.

Mr. Van Hise has stated, as a general truth, that openings in the zone of fracture of the rocky crust gradually decrease in size as depth increases, and doubtless many of you have had occasion to observe, as I have, cases where the opening of a given fissure vein decreases very perceptibly as distance from the original surface increases, and that a fissure-opening that may have a width of many feet in its upper part, if followed to sufficient depth, is found to end in a series of very small cracks whose width is to be measured in inches rather than in feet. It would seem, therefore, that the natural conclusion to be drawn from the extreme narrowness of the fissures in the Cobalt region is that they were originally formed under the pressure of a great weight of superincumbent rock or at great depth below the then existing surface; hence that the greater part of these original fissures has been eroded away, and what we see today are merely the roots of veins that once could have been measured in thousands rather than hundreds of feet. The question then is, what evidence is to be found in the geological history of the region that would

justify this conclusion? Let us search and see.

The geology of the region to the north of the Great Lakes and west of Hudson Bay has not yet been worked out in detail, but its general character is assumed to be a great plateau of low relief, composed largely of pre-Cambrian rocks in which are patches of early Paleozoic beds that have escaped erosion, presumably through being enclosed in synclinal troughs, in like manner as have the Triassic beds which are found to be infolded with the crystalline schists in the Piedmont region west of Washington. The veins, as has been seen, cut through both series of pre-Cambrian rocks as well as the igneous rocks that have been intruded into them, but so far as known did not penetrate the Paleozoic sediments, and are hence assumed to be of pre-Cambrian age. From the manner in which the exposures of the two unconformable members of the latter series are distributed, it is evident that there must have been a considerable period of erosion before the Paleozoic beds were deposited over them, though there seem to be no criteria for estimating the length of that period. Since these beds were deposited, however, and the region has been again raised above the sea, it has been exposed to sub-aerial degradation continuously up to Glacial times, which in itself is a much longer period than the entire existence of the ores of Mesozoic or Tertiary age, which constitute by far the greater part of the ore deposits of the Rocky Mountain region. The evidence afforded by the peculiar character of the phenomena of secondary enrichment at Cobalt furnishes, to my mind, a still more convincing argument in favor of the assumption that the veins, both primary and secondary, are extremely old and have been exposed to degradation for an immensely long period, for secondary enrichment and degradation are processes that go on *pari passu*, and in a given region are necessarily coördinated. It seems fair to presume, then, that the erosion and wearing away by the continental glacier was only the emphasizing of a similar process that had been going on, though at a slower rate, for much longer periods of time. Secondary enrichment of ore deposits proceeds in a sort of arithmetical progress. As the vein with its enclosing rocks commences to wear away, certain of its metallic contents, rendered soluble through oxidation, are leached down and redeposited at a lower level, which we call the zone of sulphide enrichment because the ore in that region is abnormally enriched. But this enriched zone is gradually brought nearer the surface by continued wearing away of the latter; hence increasingly richer material is carried down, and the zone of secondary enrichment is constantly increasing in richness; but the primary ore beneath this zone, which is not reached by the enriching solutions, remains constant and unchanged in the condition in which it was originally deposited. Thus there seems no limit to the amount of enrichment that may take place, provided sufficient vertical extent of original vein is provided, and enough time allowed for wearing it down to its roots.

The exceptionally rich ores are not confined at Cobalt to any single mine, or to the veins in any one formation, and the change from bonanza ore running several thousand ounces to that containing only enough to be counted on the fingers is abrupt and rapid wherever it takes place. It is a change, moreover, that can not be explained on the assumption made by the Canadian geologists, that the silver is a later addition to the contents of the veins, if by this they mean, as I assume they must, that it came from the same general deep-seated source as did the cobalt and nickel. For if such were the case, it is impossible to understand why the rising solutions should carry up their silver contents, practically without spilling any by the way, until they had nearly reached the surface, and then suddenly dump the whole load within an extent of comparatively few feet. Furthermore, it does not appear that the secondary cracks have extended below the bonanza zone. Hence the assumption of exceptionally long periods of erosion, and correspondingly great vertical extent of veins that have been eroded away seems, if the facts have been correctly interpreted, to be the only explanation that suits the case.

The chemistry of the processes of secondary enrichment that have gone on here presents some new and interesting problems, that are well worthy the attention of those geologists who have the necessary time and energy to devote to it. Hitherto we have had to do in such studies only with the sulpho-salts of the metals, but in the present case it is their combinations with arsenic and antimony that form the predominant minerals. In the present reasoning it is assumed that the chemical action of the latter would have been of the same general nature, differing only in degree from that of the former, but the actual reactions that take place are probably more complicated, and stand in need of special investigation in the laboratory. The sulphates of the metals are in general more or less soluble and are carried down in descending atmospheric waters to be reduced to sulphides in contact with large masses of unaltered sulphides. For the present it is assumed that the same is true of analogous compounds of arsenic and antimony. Precipitation takes place more readily in proportion to the relative insolubility of the sulphides. Now the silver sulphides are relatively more insoluble than cobalt, nickel, or iron sulphides, and silver, moreover, is, next to gold, the metal most readily reducible to the native state, so that it is easy to understand that it may be precipitated in the metallic state, as well as in the state of sulphide or arsenide. On the other hand, in reapproaching the surface, this metallic silver may easily combine again with sulphur or arsenic, to form a sulphate or arsenate, in the presence of sulphides and arsenides of the other metals that are being oxidized, and then resume its downward course.

The safest guide in reasoning about such deposits is the study of analogous forms of ore deposits whose geology has been carefully worked out. A most instructive parallel is furnished by the deposits of Kongsberg in Norway as described by J.

H. L. Vogt.* These deposits occur also in pre-Cambrian rocks, intruded by both acid and basic eruptives, but the significant point of resemblance with the Cobalt deposits is that the greater proportion of their value lies in the native silver. The very rich ore is found where the veins cross the fahlbands (or brown bands) which are belts of schist impregnated with pyrite. It had long been a puzzle to geologists to understand the reason for this enrichment in the fahlbands, and to Vogt apparently belongs the credit of determining that it was because of the presence of pyrite, which he assumed had by partial decomposition given out enough sulphuretted hydrogen to precipitate the silver from its solutions as sulphide. In these mines it is not uncommon to find bunches of native silver with a core of argentite, and native silver forming a thin coating over masses of argentite or projecting out of them in wire form. Similar phenomena are found in connection with the relatively rare occurrences of proustite (the sulph-arsenide of silver). Hence he reasons that the native silver must have resulted for the most part from the reduction of the sulphide in the presence of carbonaceous matter, so-called anthracite, which also occurs. (Graphite is said to be found at Cobalt.) Some of the silver, he reasons, must have been deposited as native because it rests at times directly on galena, blende, etc. At the time Vogt wrote, the theory of secondary enrichment as it is now understood had not been developed, and it does not appear from his descriptions whether there are any secondary fractures such as would have admitted of enrichment by downward-seeping waters, but from the manner of occurrence of the ores it seems likely that this process must have been an important factor in forming these deposits, and that they might be detected if specially sought for. His assumption, as was natural at that time, was that the present distribution is that of original deposition, the only secondary action having been the reduction of the sulphide. In the Kongsberg mines native silver is still found at depths of about 500 metres, but the tenor of the ore is said to have fallen off very greatly with increasing depth. They differ from those of Cobalt in carrying no such large amounts of cobalt and nickel, and in being prevailingly sulphides, rather than arsenides and antimonides. They are the only other important mines that I know of in which the main value is in native silver, the proportion of sulphide ore being estimated by Vogt at 5 to 10%, while others have assumed it to be even less. The total production of the Kongsberg mines is estimated to have reached a value of over 137 millions of marks, while Cobalt is producing today over 20 million ounces of silver per year, and bids fair to produce as much or even more for many years to come.

Accidents in mines are very often the result of carelessness—most often of the victims themselves; for miners are notoriously unmindful of the dangers about them.

Jour. f. Prak. Geol., Vol. VII (1899), p. 113.

Kern River Oilfield

By J. H. G. Wolf

In reviewing the output of the various oilfields of California, one of the most striking showings is the wonderful uniformity of the yield of the Kern River field. Watts, in his valuable work, the 'Oil and Gas-Yielding Formations of California',* gives the number of producing wells in Kern county in August 1909 as 163, distributed as follows: Kern River field, 130; Sunset field, 17; McKittrick field, 16. The yield for Kern county that year was (U. S. Geol. Survey figures) 892,550 bbl.; it is probable, therefore, the Kern field produced 750,000 bbl. in 1900, its initial producing year. By 1901 the wells of the Kern River field had increased to 559 in number, and the county's yield to 4,493,455 bbl.; the following year there were 800 wells, and the yield 9,705,703 bbl., while by 1903 the yield of the county had leaped to 18,077,900 bbl. annually, and that of the Kern River field to approximately 14,000,000 bbl. The latter year marked the building of the pipe-line to tide-water (Kern River field to Point Richmond on San Francisco bay, 278 miles) which afforded a convenient and economical method of transport for the oil, steadied production, and built up markets.

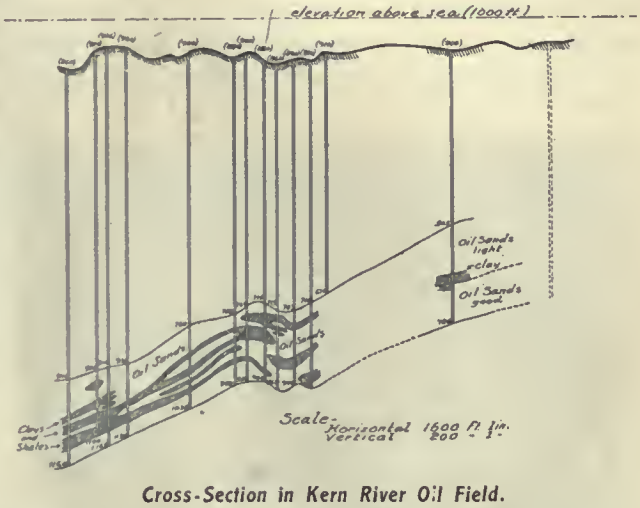
From 1903 to 1909, inclusive, the Kern River field produced a net of from 13,000,000 to 14,500,000 bbl. annually (the latter figure being for 1909), while by December 1909 the number of producing wells had increased to 1375 of the 3950 wells on the beam in California at that time. The output fluctuated with price and consumption, yet the area from which the supply was drawn was not extended after 1901, and up to March 1910 it remained practically constant at nine square miles. The southwest and northeast sides of the field are being extended now with satisfactory results, which will add to the area to be pumped. The net yield of Kern county, or the amount actually shipped in the ten years from 1900 to 1909 was 139,296,609 bbl., according to the U. S. Geol. Survey. Allowing one barrel for producing and marketing seven, and disregarding the quantity consumed in development work, the gross production was probably 159,196,124 bbl., of which the Kern River field produced at least 125,000,000 and possibly 130,000,000 bbl. Statistics present dry facts unless put in a form to be digested and to bring out the commercial importance of what is under consideration, or to permit scientific facts to be deduced therefrom.

Referring directly to what may be taken from the figures presented by the Kern River field statistics, the following summary is given: (1) The 800 producing wells in 1903 yielded a net of 17,500 bbl. each. (2) The 1375 producing wells in 1909 yielded a net of 10,600 bbl. each, hence apparent decline in yield per well in six years on the assumption that all the wells were drilled in equally prolific ground (which is not true) was, roughly 39%. (3)

*State Mining Bureau, Bulletin No. 19, 1900.

The gross yield of 125,000,000 bbl. came practically from 3000 acres of developed or drilled-up land, representing one well to 2.25 acres; hence the gross yield per acre was 41,700 bbl. (4) If the decline in yield per well was 39% in six years, and the quantity extracted 41,700 bbl. per acre, the gross to be extracted from these 3000 acres is theoretically 107,000 bbl. per acre, or the 6000 acres of the field may yield a gross of 642,000,000 bbl. petroleum. (5) It is neither safe to estimate nor is it reasonable to suppose that the rate of decline in yield will continue constant at the above figure, nor that the amount of oil that can be extracted profitably will equal that theoretically extractable; nor is it correct to assume that the pumping from the 3000 acres already developed has not drawn down the general oil-level, or its general plane. It is allowable to assume, however, that the developments of the present edges of the field will extend the area to be pumped possibly 10%, that methods will be devised to extract the oil which is mingled with water in the sands above the main oil measures, and which is not sought now, and that when the field is fully drilled and the wells are reduced to producers of from 2 to 5 bbl. each (as the wells in the Los Angeles fields are today), cheaper methods of pumping will then have been devised. Experiments in pumping with electric motors will be attempted in 1911. In light of these considerations, it may not be far wrong to place the amount of oil in the ground at the theoretical 642,000,000 bbl. The Baku field in Russia produced between the years 1859 and 1897 the enormous total of 648,000,000 bbl.; the field is still producing and yielded during 1908, according to the statistics of the U. S. Geol. Survey, 55,863,000 bbl., or 90% of the output of the Russian field. The physical conditions under which the deposit exists in the Kern River field are more like those of the Baku than any other prominent field ever opened; that is, the oil lies in a gravelly reservoir in strata of fine and coarse sands mingled with kidneys of clay and shales, the formation being incoherent, as are also the covering strata. The sketch in the next column is a cross-section taken across the north side of the field along a section line. The dip of the oil-formation along that line is 2° 24′. (6) The theoretical period of exhaustion of the 1375 wells pumping on January 1, 1910, on the premises stated in (4), is 15 years, hence the date of the ultimate exhaustion of the field is dependent upon the rate at which the drilling of the future is conducted, and upon the manner in which the encroaching water is handled. (7) During the calendar year 1909, seventeen properties on the north side from which figures were obtainable marketed from 143 wells drilled upon these particular properties, whether old or new wells and whether or not each well was kept constantly pumping, a total of 1,802,937 bbl., or 13,608 bbl. per well per annum, which is 2008 bbl. above the average for the field for 1909. The property which made the best showing was on the north edge of the field and yielded 17,760 bbl. per well. This production of 1,802,937 bbl. was drawn from 295 acres of developed ground (one well to 2.06 acres), or the net product per acre was 5820 bbl., or 6650 bbl., gross.

The foregoing exhibit shows that each acre of developed ground in the Kern River field has produced to date 41,700 bbl. petroleum. How much more is extractable is not known, because of the ever-recurrent question, when will the water drown out the oil measures? Judging from the way the present encroachment is being handled in the southern portion of the field, the loss in the yield from this source will not be a serious one for some years. There remain approximately 3000 acres of proved ground to be drilled, much of it situated in the heart of the field, where the original saturation was very high. Another method of calculating the possible yield is by taking the thickness of the oil



Cross-Section in Kern River Oil Field.

sand to be an average of 200 ft. and, assuming the voids in the sands to approximate 35% and all completely saturated, there are 70 ft. thickness of oil and gas under each acre of ground. If 50% of the above 70 ft. be extractable, and the gas content be 50% of the latter, the number of feet of solid oil extractable is 17 ft. 6 in., or 135,625 bbl. per acre. The gas-pressure, however, which is the principal means for the expulsion of the oil from the measures, will have died down long before any such quantity is recovered from the area, and the ultimate yield, therefore, is a matter of conjecture and not of precise calculation.

Bulldozing is a term used to indicate the process of breaking large boulders in open-cuts, or in stopes, by placing powder on top of them and exploding it in the usual manner. At some mines the men place pieces of rock, weighing from 3 to 10 lb., on top of the charge of powder, presumably to prevent the fuse from being shaken loose by the discharge of neighboring shots. The practice is an extremely dangerous one, for these pieces of rock fly through the air to incredible distances, and are a far greater menace to the men than the fragments flying from the boulder itself. If the charge of powder and the fuse require protection such as suggested, a few handfuls of sand or of fine rock will answer the purpose just as well as a lot of rock fragments, and the fine material is without danger.

Valdez Creek Placers

*Valdez creek is one of the upper tributaries of Susitna river, which flows into Cook inlet. It is about fourteen miles long and lies in the mountains flanking the Alaska range, flowing into the Susitna from the east. Its broad valley is floored with gravels that are largely the product of glaciation. All its largest tributaries rise in the mountains south of Valdez creek. They include Timberline, White, and Roosevelt creeks. Rusty creek and Lucky gulch are tributaries of White and Roosevelt creeks, respectively. The total gold production of the Valdez Creek district up to 1910 has been approximately $260,000.

The most productive part of Valdez creek proper is the lower two or three miles of its course and includes about one mile of the stream. In addition to the placers of the creek, Lucky gulch, which is about seven miles from the main Valdez Creek camp, produces gold and, as has been intimated, prospecting on Rusty creek during a number of years has given good grounds for believing that that stream also will become a gold-producing stream. During 1910 most of the mining on Valdez creek was confined to four creek claims and to the Tammany bench claim. Mining began here in 1903 and at present the richest part of the creek claims, so far as they are known, are nearly worked out. The Tammany bench claim, however, which is the richest property yet discovered in the region, continues to yield as it has in the past, and there is no reason to suspect that it will not do so for some time to come. This part of Valdez creek flows in a canyon cut in slate and the overlying gravel deposits. The canyon has its greatest depth, 170 ft., in the vicinity of the so-called Monahan tunnel, which is the adit to the Tammany bench, just mentioned.

The gravel ranges from 3 to 8 ft. in thickness and consists of slate, schist, and granite, together with a small proportion of light colored porphyritic intrusives and dark basaltic and tuffaceous material. The gold of Valdez creek differs considerably in appearance. Part of it is flat and smooth, but another part is rough and little worn. Much 'ruby sand' and a little 'black sand' is associated with it. The gold-producing gravels of the Tammany bench fill an old canyon formed long before the present canyon of Valdez creek was cut. It intersects the present canyon at an angle of about 45°. Its bottom is 60 ft. above the level of the creek, so that the Monahan tunnel is at that elevation also, thus affording an excellent dump for the washed gravel. Most of the gold is found in the lower 5 ft. of the gravel, and the output of this tunnel alone is nearly half the total production of the district.

Lucky gulch is occupied by a small stream, little more than a mile long, coming down from one of the mountains south of Valdez creek. It is a narrow V-shaped gulch cut in slates that dip to the north at about the same rate that the stream falls. A notable feature of Lucky gulch is that a large portion of its gold is in coarse nuggets, two of which weighed 52 and 32 oz., respectively. Owing to its situation on the north side of the mountain and to its small drainage area the stream derives its water largely from melting snow, and its flow in consequence is at times inadequate for use in mining.

Rusty creek, the largest tributary of White creek, is four and a one-half miles east of the camp on Valdez creek. It heads in a complex of slates, tuffs, and basalts, but most of its course is in slate. Prospecting has been done on Rusty creek for three years, yet it was not till 1910 that results of much promise were obtained. A large cut, several hundred feet long, was made in the creek bed by 'booming.' The gravels filling the old gulch, as it seems to be, include an upper deposit of unsorted glacial débris, from 10 to 20 ft. thick, made up of basalt and slate. Below this is another deposit of fairly well sorted gravel and coarse sand with distinct cross-bedding. The cut contains many large boulders, derived chiefly from the upper glacial deposit. Most of them are of basalt, but a few are of granite. The cut is 25 ft. deep in places and has a rock wall on its east side, but its west wall is gravel. Small benches on the rock-wall side yielded good prospects in gold all the way down, and the bottom of the cut was especially encouraging. The stream gives good promise for future production.

The Tammany bench claim and the adjoining creek claims are favorably situated for hydraulic mining. Valdez creek affords an abundant supply of water under good head which can be utilized with comparatively small expense and labor. The creek provides dump room.

Two difficulties that the miner must face in this district are the high cost of transportation and the unusual proportion of large boulders in all the gravel of the main stream. Rusty creek is somewhat more fortunate in respect to the boulders, for it was out of the influence of the glacier that moved down Valdez creek, and thus did not receive the large contribution of diorite boulders that filled the main stream. Freight rates from Valdez to Valdez creek average approximately 30c. per pound, but there should be some reduction in this rate when the Copper River & Northwestern railway is completed. The improvements that have been made in the military road from Valdez to Fairbanks will also make the conditions for mining on Valdez creek more favorable, since it will lessen the difficulty of communication with the outside. Valdez creek is 65 miles west of Paxsons, on the military road, but there is no well-marked and regularly traveled trail to the road, since there is little summer travel between them. Freight is brought in during the winter by way of Gulkana, Maclaren, and Susitna rivers, which afford an excellent winter trail.

*Condensed from a report now being prepared by Fred H. Moffit, of the U. S. Geological Survey.

Some of the early-day hydraulic-mining plants in California cost over $500,000. This included reservoirs, ditches, flumes, and the other improvements necessary to the operation of the mines.

An Old California District

By A. F. McEwen

Sawyer's Bar is on the north fork of the Salmon river, about 65 miles from the railroad at Yreka in Siskiyou county, California, and in days gone by was a little place. The region in general is very mountainous, Tanner's peak, one of the highest points in the vicinity, being 7000 ft. above sea-level. The properties here described are at altitudes ranging between 1500 and 2500 ft., above the north fork of Salmon river. Timber for mining purposes is abundant. The old 20-stamp mill and other machinery at the property I examined recently were driven by electricity, the power (which could be considerably augmented) being furnished from the river at Sawyer's Bar. Water for milling and domestic uses is readily available. The annual snowfall is fairly heavy, though the seasons vary considerably in this respect. The orebody, from 2 to 5 ft. wide, is between slate walls, and consists of quartz, carrying arsenopyrite. As thus far exposed in the various workings, these quartz-veins lie somewhat flat. The average dip may be set down as 15°, with a strike a little east of north. As a matter of fact, the dip of the vein varies considerably throughout this entire zone, and at certain points on the property the vein takes a sudden and steep (45°) inclination. Winzes have been sunk at such spots in one or two instances, but at the time of my visit these were full of water, and in any case (as far as I can gather) the work was altogether inconclusive in its bearing on the question of dip, at increased depth.

Sawyer's Bar, Siskiyou County, California.

As a result of the conditions here, notably the dipping of the vein into the mountain at a small angle, and the subsequent heavy erosion of the mountain itself, the vein is exposed along its dip at sundry points for a distance equivalent to several thousand feet, if these points were in line with each other on the dip, which they are not. From this same point of view a vertical depth of about 1000 ft. may be said to be attained between two of the adits which were driven on the vein; although it must be understood that these adits are a long distance apart horizontally. Evidences of considerable movement in the vicinity of the vein are abundant, such as contortion of the slates, the frequent presence of gouge matter, etc. This extensive property was opened up by numerous adits, driven usually on the vein itself from its exposed outcrops on the mountain-side. Many of these workings are now, of course, quite inaccessible; but, as far as was practicable, I carefully sampled the whole of the ground. Some extremely rich ore has undoubtedly been taken out in the past, and although at the time of the last run in 1908 all the ore then developed was put through the old 2-stamp mill, good assays can still be obtained over fair widths of vein at several underground points. A 2-in. seam of banded quartz, containing rich sulphides, assayed by myself, yielded $1611 in gold per ton; while 27 in. of quartz overlying this same rich streak, assayed $11 per ton. The average assay value of the ore treated in the past seems to have been from $10 to $12, but the loss in the tailing was heavy.

These properties have been operated intermittently for at least 47 years, and have several times changed hands. Statistics of their production for this period are uncertain. Still from the data available, it may be safely stated that the gross output has been in the neighborhood of $600,000 or $700,000. Assuming it to have been satisfactorily established that the placer gold, recovered from what is known as Eddy's Gulch basin, below the quartz properties in question, was derived from the disintegration of the gold-bearing veins, which exist in the mountains above, the yield of placer gold becomes a matter of some interest. The north fork of Salmon river in Siskiyou county is credited with a production of $25,000,000 during 60 years of placer operations. It is estimated that Eddy's gulch, which runs into the north fork of Salmon, has alone yielded over $3,000,000. As a matter of fact, hydraulic mining is still in progress on a small scale. Concerning the future outlook for the quartz properties, I may say that exploration might reasonably be undertaken at a number of points underground with a fair prospect of success.

The depth at which water may be reached in an undeveloped mine, and the amount that will be present when it is reached are very uncertain. At many mines the water-level is surprisingly near the surface, and in this altitude and topography have little influence. For instance, on Mount Union, southeast of Prescott, Arizona, the water-level in mines not drained by adits is close to the surface. This is at an altitude of nearly 8000 ft., though down the valley of the Hassayampa river, which heads on Mount Union, there are mines over 200 ft. deep in which no water has been found. Some mines make a large volume of water between the surface and the 1000-ft. level, but little or none below that depth. The Silver Islet mine, situated on a small island in Lake Superior, was worked to a depth of 500 ft., and was a remarkably dry mine.

Tin in Malaya

By F. Douglas Osborne

*The chief sources of the world's tin supply are the Malay Peninsula, the islands of Banca and Billiton, Bolivia, Australia, Tasmania, Cornwall, Nigeria, the Transvaal, Swaziland, and China. Tin is also produced in New Zealand, Burma, the Congo Free State, Korea, Japan, Spain, Portugal, Central Europe, France, and Alaska, but not in important quantities. Of the sources named, the Malay Peninsula is the most important, as from there comes more than half of the total supply. Situated at the southeastern extremity of the continent of Asia,

Malay Peninsula.

the Peninsula consists of a narrow strip of land varying in width from less than 50 to nearly 200 miles, and extending from latitude 13° 30′ N. to 1° 18′ N. The northern part of the Peninsula is feudatory to Siam, and in this part the mineral resources have hardly begun to be developed. Toward the south are the Federated Malay States, which, under British protection, have so wonderfully developed during the past thirty years. It is from these States, Perak, Selangor, Negri Sembilan, and Pahang that the majority of 'Straits Tin' comes. In 1909 the amount exported was little short of 49,000 tons.

That mining for tin in these States has been going on for long years, there is evidence in the form of old workings all through the country; but it was not until the advent of the Chinese that any considerable quantity was produced, and only since their factional fights, which led to British interference and subsequent protection, that the States have rapidly developed and become the mainstay of the world's tin supply.

The tin exported from the Federated Malay States is almost entirely won from alluvial deposits. The most important of these are in Perak and Selangor, Perak being at present responsible for about 56% of the total. From the Federated Malay States during the twenty years, 1890 to 1909, there has been produced 873,703 tons of tin, or an average of 43,685 tons yearly. This production was distributed as below:

	Tons.
Perak	447,900
Selangor	329,564
Negri Sembilan	73,315
Pahang	22,924

The maximum production was made in 1905, when the output for the States reached a total of 50,991 tons; since then the production has diminished slightly, 48,743 tons being produced in 1909, and it appears as if there will be a greater falling off during 1910 (total, 45,000). Almost the whole of this production comes from alluvial workings, as at present, with the exception of the mines of the Pahang Consolidated in Pahang, and some workings in the Kledang range of hills near Ipoh in Perak, no lode mining is carried on, and the total production from these two sources does not exceed 1200 tons per annum. The chief centres of the alluvial workings are the Kinta valley in Perak and the flats near Kwala Lumpur in Selangor drained by the Selangor and Klang rivers. In these places it is hardly an exaggeration to say that tin occurs everywhere, from the surface of the ground down to depths of 250 ft., on the flat land, in the valleys, and high up on the mountains.

The Kinta valley, which is so enormously rich in tin and which is typical of the characteristic deposits, is the valley drained by the Kinta river, the most important tributary of the Perak, with which it runs parallel in a southerly direction, the Kledang range forming the watershed between the two rivers and the boundary of the Kinta valley on the west. On the east of the valley is the main range of the Peninsula. The valley is about 30 miles long by 12 wide and is very flat, the mountains on each side rising abruptly. Mining villages, well laid out and tidy, are scattered throughout, connected by well made cart-roads, and the main railway runs through the centre. The main geological features of the valley may be described as a floor of highly crystalline limestone or marble, usually white in color, and lying in the centre of the granite mountains. On the east side this limestone forms a series of wonderful pinnacles or hills, rising in cases as high as 2000 ft. above the surrounding country, covered by dense jungle scrub, and honeycombed by caves and fissures. It has been weathered to a very irregular surface, forming innumerable small pinna-

*Abstract of a paper read before the Royal Society of Arts, London.

cles and crevices, is non-fossiliferous, and its geological age is unknown. The mountains on either side are composed of intrusive granite, which has doubtless been the cause of the upheaval and contortion of the limestone, the intrusion of the granite having probably occurred simultaneously on both sides of the valley, and thereby squeezed the limestone into the extraordinary shapes which it has assumed.

The tin deposits are extremely irregular and follow no well defined lead. The richest occur in the vicinity of the granite foothills, much tin being occasionally concentrated in the fissures left at the junction of the granite and limestone, as in the case of Tronoh and Lahat. The channels and crevices in the limestone valley bed invariably are rich in tin, and it is from these shallow deposits that the majority of the tin is won by the Chinese workers. The tin wash may be sandy or heavy clay; it may occur in layers separated by barren ground, or the whole of the ground from surface to bedrock may carry tin; and as in the valley the holes and crevices in the limestone are filled with tin-bearing ground, so it is in the hills, even up to heights of 1200 and 1300 ft. Isolated deposits from time to time are found in the limestone, the most notable of these being the Tambun mine, from which in 1903 as much as 350 tons of tin ore was won during one month, and the average for the year was some 250 tons per month. There being no connection between this deposit and any other of considerable value makes it all the more difficult to evolve a reasonable theory as to the origin of the mineral, more especially as, in the case of Tambun, the tin is much less water-worn than is the case in many of the cave deposits in the hills, which are much closer to the granite ranges, from the weathering of which the alluvial tin was most probably derived. Mr. Scrivenor, the government geologist, is of the opinion that it is much more probable that the bulk of the alluvial tin has been derived from the masses of pegmatite, lodes, and stockwerks which take part in the formation of the low rolling country at the foot of the high ranges, than that it was derived from the high granite mountains. In his report for 1904 he states that undoubtedly the bulk of the tin found in the Tronoh mine had its source in the hill lying to the west of the mine.

If this theory is accepted, it becomes still more difficult to account for the presence of alluvial deposits high up in the limestone caves and on the mountains. My opinion is that the bulk of the tin deposits of the Federated Malay States came from the weathering and erosion of lodes that existed in the granites and schists. Even close to the foothills, the tin deposits are almost invariably much water-worn and rounded, which naturally leads to the conclusion that they have traveled a considerable distance. Then, if the tin came from high granite hills, it is a simple matter to account for its presence in the high caves and fissures of the limestone cliffs, for where the granite pushed through and distorted the limestone, huge crevices are left which would catch the detritus subsequently washed down from above, and, acting as receptacles for large bodies of water, hydraulic power would be provided, capable of forcing the alluvium through channels in the limestone and to considerable heights.

Most of the tin is found on the west side in an almost continuous line from Taiping to the north to Seremban to the south, and an interesting feature is that their extent and value seem to diminish toward the south. From this it might be deduced that the main source of the supply was the mountains of Perak. On the east coast the tinfields are less numerous, and more scattered; the deposits are of a more recent period, and, as the bedrock of the alluvial workings is generally granite rock, there seems but little likelihood of discoveries being made here of new fields which will equal in richness those on the west coast. It is probable, however, that

Federated Malay States.

lodes of considerable importance may in time be discovered and worked in the eastern States.

For the development, in the future, of the tin resources of the Federated Malay States there is no doubt that modern machinery and abundant capital are necessary. The shallower, richer, and easier-won deposits having become exhausted, those remaining require, for their development, modern engineering skill and plant capable of treating large quantities commercially. The methods by which alluvial deposits are worked may be described under four heads: (1) Ground sluicing, with its modern development of hydraulicking; (2) open-cut workings; (3) underground workings; (4) dredging.

Ground sluicing is only practicable where a sufficiency of water is available and an outlet for the débris. It is a favorite form of mining for small parties, little capital being required. The scene of this class of operations is, generally speaking, some narrow valley up in the hills. Of hydraulicking it is not necessary to say anything, as the method is well known. No bucket dredging has so far been attempted in the Federated Malay States, though

the use of bucket dredges for the recovery of gold and tin from the river beds and flats is general in Australia and New Zealand. Dredging by centrifugal pumps is a modern adaptation of the principle of hydraulic mining, and was first introduced in Australia. Essentially it is hydraulicking at a low level, the difficulty of getting rid of the tailing being met by the introduction of a centrifugal pump which raises it to a height at which it will find an outlet by gravitation.

For the future development of the tin resources of the Federated Malay States, plants of this description must be the mainstay if cheap power can be procured. Already it has been demonstrated practically that ground which has already been worked Chinese fashion, and abandoned as exhausted, can be worked profitably, and it needs only the introduction of some more economical means of generating power than is at present available, for the thousands of acres of so-called exhausted tinfields to be profitably re-worked. The substitution of suction-gas for steam has already met with a considerable measure of success in the Sungei Raya mine in Kinta, where the plant has been intelligently treated, and there is a scheme in prospect for generating electric energy by the water-power of the Kinta river. Should this scheme be carried to a successful issue, working costs, where its electric energy is employed, must be reduced to such a low figure that but little land in the Kinta valley and other mining fields is too poor in tin to be profitable.

So far the alluvial resources only have been dealt with; but, in addition to these, there are the lodes to be developed, and in a country where such abnormally rich alluvium has been found, all of which at some period must have come from the decomposition or erosion of metalliferous veins in the rocks, it is but reasonable to presume that time and patience, with the assistance of capital, may discover the sources of the alluvial supplies and develop them into profitable tin-producing mines. Already a company has begun to develop the lodes in Perak and Pahang. So far, in Pahang, the majority of the tin won has been found in the slate country, overlying the granite, none of the lodes having been followed through the slates into the granite. The property of the Pahang Consolidated Co. at Sungei Lembing (formerly owned by the Pahang Corporation and the Pahang Kabang Co.), has been worked for over twenty years, and it is said that more than thirty lodes have been discovered, having an east-west course, the angle of dip varying from 10 to 40°, according to W. H. Derrick. The country in which the lodes have been worked is schist or slate overlying the granite. Mr. Scrivenor, the government geologist, considers that the lodes here are fissure veins, and expresses as his opinion that they will continue to great depth. Certainly the lodes can in some cases be traced into the granite, but the measure of success that has so far rewarded the liberal development policy of the Pahang Consolidated Co. is so small that an opinion as to the future value of the property can not be formed.

Treatment of Silver Ores at Guanacevi, Mexico

By R. C. Kline

The Guanacevi district, situated in the northwestern corner of the State of Durango, has for many years borne an important part in Mexico's production of silver and its yearly output is still not inconsiderable. Owing to the comparative inaccessibility of the camp, lack of cheap power, and highly refractory character of most of the ores, little progress has been made in handling the ores of low value. There is now a strong probability that a line of railroad will shortly be built in from Tepehuanes, and if this be done the situation should be very much improved.

Upon my arrival in Guanacevi in the spring of 1907, I found that none of the companies in operation at that time were successfully cyaniding their ores. One company was getting ready to build a new cyanide annex to its concentrating mill, while another was still trying to get a satisfactory rearrangement of their equipment and was putting in some of the more modern devices at the disposal of the metallurgist. Former attempts to treat by coarse crushing, with separation, leaching, and air agitation in flat-bottom tanks, had proved complete failures. This work had been done before much of anything was known regarding the cyaniding of silver ores, and the results in no way reflect discredit upon the men who were responsible for them.

The first company for which I examined ores was developing a portion of the Santa Cruz vein. The ores of this vein may be divided, for purposes of this article, into two classes: oxidized and unoxidized. It is concerning the oxidized ores that I shall write. These apparently varied little in their metallurgical composition, but yielded vastly different percentages of extraction under identical conditions of treatment. Oxides of iron and manganese were present in considerable quantity, together with small amounts of zinc. The ores nearer the surface showed less zinc than those from deeper levels, but contained approximately as much manganese, in the form of pyrolusite, as did the others. This fact is interesting, since the presence of pyrolusite in considerable quantity is believed by many to be the cause of poor extraction; yet the ores from the upper level of the property in question yielded over 90% of their silver without any special difficulty. A curious point in this connection was the fact that the ores from the second level yielded a much poorer extraction; those from the third level also poorer, but better than those from the second; while those from the fourth level gave a good extraction, considering the nature of the ore, in fact almost equal to those from the first. Black oxide of manganese was present in practically the same amount in all four samples, and its presence could have, therefore, little bearing upon ultimate results. Nor would it appear probable that the varying extractions obtained were due to intermediate oxidation products

of the manganese minerals, even though many of the unoxidized ores of the district show heavy percentages of pink rhodochrosite and rhodonite.

Work on the above ores was begun by crushing in solution to a total product, or 'slime,' all of which would pass 200 mesh. The crushing dilution was about 8 to 1. Agitation was carried out for varying periods and with different dilutions. The resulting extraction of gold was excellent, and although the gold value of the heading was low, in no case did I find over 8c. per ton in the residues, while they more often assayed as low as 5c. This figure is perfectly trustworthy, as from 40 to 50 buttons from 1 A. T. charges were always combined and parted for a gold weighing. The use of chemical agents such as lead acetate, barium peroxide, mercuric chloride, ammonium chloride, and bleaching powder, was thoroughly tried, but in no instance with any appreciable benefit. The effect of varying dilutions showed very clearly that anything greater than three of liquid to one of solids was of absolutely no benefit, with the possible exception of a very slight cut in the time required for completing solution of silver. This was not sufficient to balance the increased cost of equipment and power, for the larger quantity of material. This is strictly in line with later experience of others, and of my own. The increase in time of agitation, from 24 to 30 hours, in every case showed that the added cost for power and tankage was more than repaid and the results were consistent. Periods of agitation greater than 30 hours did not, however, show any material or commercial profitable increase in extraction of the silver. Concentration tests, carefully made by passing the material over a small canvas table, showed in every case that after treatment had been completed, the concentrate did not contain enough to pay costs of concentration, freight, and treatment charges. This matter was thoroughly checked and concentration, as a commercially profitable means toward treating this class of ores, was eliminated.

It will be noted that my method for deciding the advisability of concentrating an ore, is to extract the concentrate from a sample of the ore which has already been subjected to cyanide treatment. This, in combination with a narrow and long canvas table, which ensures catching the fine material, gives conclusive evidence one way or the other and can be afterward checked by tests on fresh portions of the sample containing the concentrate and others free from sulphides. The latter tests will show the additional consumption of chemicals, if there be any. At the time this work was carried out, Charles Butters had comparatively recently presented to the metallurgical world his admirably effective vacuum-filter and most millmen believed in giving at least one extra wash and decantation to a slime charge before sending it to the filter. More often they gave three or four. We were pretty well fixed in our ideas on this matter, at least those of us who had had previous experience with the old type of filter-press, in which, owing to the segregation of the crystalline portion of the charge in the lower part of the cake frame, complete washing of the colloidal, or upper portion, was impossible. E. M. Hamilton proposed and adopted the modern slime treatment, whereby the charge, after having been subjected to agitation until solution of metals was commercially complete, was settled, decanted, and the thickened pulp run direct to the filter, there to be washed practically free of soluble metals. This mode of procedure he had already adopted at the numerous mills of the Charles Butters company.

I tried this method on the ore in question, carefully checked it against identical samples treated by one and by several extra washes and decantations, and found that washing was practically complete on the experimental filter. In view of later practical experience of my own and of many others, these views are of course proved correct. Leaching tests on samples carefully classified wet and free from any considerable amount of colloidal slime, were made. This work, while carried out on a small scale, was entirely practical in its results, care being taken to have a leaching depth of sand equivalent to that of practical plant work, thereby giving the same conditions of packing of charge, length of column of sand through which the solution must pass, etc. Preliminary leaching tests showed that in order to obtain the best commercial result the sand must come fairly close to passing 100 mesh.

The final results were good, but when treatment was complete, the coarser material sized out, re-crushed through 200 mesh, and agitated, sufficient additional recovery of silver was shown to pay for the power and chemicals and to leave a small profit beside. Crushing through 200, or 'total sliming,' was therefore decided upon. An attempt to improve extraction by first giving the ore a sweet roast gave astonishing results, and instead of improving matters it lowered the silver extraction to a little over 10%. It would be interesting to hear of the experience of others in this connection.

The question of coarse free gold was effectively settled by a series of amalgamation tests. The crushed ore was made up to a thick pulp and, having sufficient mercury present, was thoroughly agitated in bottles. The pulp was subsequently thinned, washed free of mercury, and after dewatering, was given the regular treatment. Parallel samples were given identical treatment, but without attempting to amalgamate any gold. The results in both series of tests averaged practically the same extraction. The treatment decided upon for this class of ore was therefore essentially as follows:

1. Crushing in solution, so that no more than 2% would remain on 200 mesh.

2. When a complete charge had been milled into a tank, to add sufficient cyanide to bring the solution up to a strength of 2.5 lb. true free cyanide per ton, as determined by silver nitrate, without the iodide indicator or the addition of any caustic alkali other than that already in solution.

3. Agitation to be carried on continuously for not less than 30 hours. After decantation of the resulting solution, the charge to be run to the filter.

4. Filter-cakes to be washed, in position, with from 1½ to 2 tons of barren solution per ton of

slime, and then discharged from the filter.

5. Lime in sufficient quantity to maintain a protective alkalinity of 2.5 lb. per ton of solution in terms of sodium hydrate, to be added at the battery. In view of later practical experience with other classes of Guanacevi ores, this figure was proved to be too high, the best strength being about 2 lb. per ton or slightly under.

The unoxidized ores of the district presented a much more varied mineralogical character and a cursory description of some of the combinations encountered may be of interest. They are: (1) A clean quartz, in which the silver, as evidenced by high-grade specimens, appeared to be chiefly in the form of the sulphide, with smaller quantities of double antimonial sulphide, or stephanite. Little or no light or dark ruby silver in evidence. This ore treated easily to about 89% silver extraction. (2) A very clean ore, with little mineralization apart from the silver, small amounts of which were in the form of dark ruby, or pyrargyrite. Samples proved streaky, with regard to treatment, but the reason for this was not ascertained. Ores with gold content up to $28 per ton easily yielded over 96% extraction, with an average silver recovery of about 80% by straight cyanide. (3) A light brown ore, evidently partly oxidized. Treated to about 84% silver and over 95% of the gold. (4) A hard and heavily mineralized quartz, containing considerable quantities of pyrite and marcasite, with less galena, sphalerite, rhodochrosite, and rhodonite. It proved refractory, and an examination of high-grade specimens showed that the silver was chiefly present as argentite and stephanite, with smaller quantites of ruby silver. It yielded about 77% of its silver and 93% of its gold. (5) Ore from the same mine as No. 4 and essentially the same in character except as regards the quantity of sulphides present. It proved to be the most refractory found and yielded only 50% of its silver. About 24 hours continuous agitation was found to be sufficient for the solution of all silver capable of being removed by cyanide treatment and, as in the case of the oxidized ores, the use of other chemical agents gave no additional extraction whatever.

In view of the fact that the silver proved refractory, while the gold responded easily to treatment, in the sample, an examination of the probable chemical reactions involved in the case of the silver is of interest. This matter has already been presented in a very interesting manner by Francis J. Hobson, in a paper contributed to the *Mining and Scientific Press* some time past. I regret that I have no copy of his contribution at hand, and it must be at the risk of repeating what he may already have said in this connection, that I go into the subject.

Probably no positive knowledge of the more complicated silver reactions is available. Regarding the more simple silver combinations, it is known that: (1) Argentite and cerargyrite readily go into solution, forming double silver potassic cyanide and the corresponding alkaline sulphide and chloride, respectively; (2) that the silver thus dissolved will stay in solution in this form provided there be present sufficient zinc or lead salts to precipitate the alkaline sulphide. In treating many ores and tailings, there is enough zinc dissolved to answer the purpose, without resorting to the use of lead acetate or litharge.

With stephanite and ruby silver the case is somewhat different. It is known that these minerals are attacked by potassium hydrate, which turns them black and under favorable conditions partly dissolves them. What probably happens may best be seen by examining the following reactions. The chemical composition of the minerals in question is:

$$\text{Stephanite } (2Ag_5SbS_4) \rightarrow 5Ag_2S.Sb_2S_3$$
$$\text{Pyrargyrite } (2Ag_3SbS_3) \rightarrow 3Ag_2S.Sb_2S_3$$
$$\text{Proustite } (2Ag_3AsS_3) \rightarrow 3Ag_2S.As_2S_3$$

Under the action of potassium hydrate, stephanite, for example, would probably react as follows:

$$2Sb_2S_3 + 10KOH = 4KSbO_2 + 6KSH + 2H_2O$$

The potassium hydrosulphide thus formed would react on another portion of antimony trisulphide, thus:

$$3Sb_2S_3 + 6KSH = 6KSbS_2 + 3H_2S$$

The hydrogen sulphide formed in the above reaction might, in its nascent state, further interact with potassium hydroxide, forming nascent potassium sulphide, which would react on another portion of antimony trisulphide thus:

$$Sb_2S_3 + 3K_2S = 2K_3SbS_3$$

Of the above reactions, the first two, resulting in the formation of potassium metantimonite and metasulphantimonite, appear to me to be the most probable. It is, however, equally possible that some modification of the third, resulting in the formation of potassium sulphantimonite and potassium sulpharsenite, where proustite is involved, takes place. In any event the sulpho compounds are strong reducing agents, tending to take up oxygen and go to the mono and poly sulphoxy arsenates and antimonates. This fact takes on added importance if there be gold or native silver present in the ore.

That the action of potassium hydrate is highly beneficial in breaking down the above silver combinations, thoroughly proved by experimental work done by myself on a sample of high-grade silver ore carrying over 1200 oz. and on which ordinary treatment with potassium cyanide solution carrying enough cyanide to completely dissolve the silver, together with sufficient lead acetate to protect against re-precipitation, only served to extract some 40%. On subsequently boiling with a solution of caustic potash and resubmitting to the action of cyanide solution, sufficient additional silver was dissolved to bring the extraction up to about 90%. But while this method of recovery was interesting, from the chemical point of view, throwing some light upon the benefit to be derived from the use of strong caustic alkalies, it is unavailable in the case of practical operations, owing to the impracticability of heating up large quantities of pulp. Nor does it give uniformly good results in all cases.

The use of strong caustic soda solution failed to give satisfactory results. It is probable, therefore, that potassium hydrate is much more active, and this appears to me to be an added argument in favor of

the use of potassium cyanide in the treatment of silver ores, instead of the sodium salt, since the presence of other alkaline hydrates, such as calcium hydrate, would in the natural course of the process, liberate corresponding quantities of potassium hydrate. In fact, the activity of potassium hydrate explains perfectly the beneficial effect derived from the use of the leach liquor from wood ashes. During the year 1905, at which time I was in charge of the treatment at the Creston Colorada mill, at Minas Prietas, Sonora, I began the use of wood-ash leach, through the advice of M. F. Perry, manager of the Grand Central at that place. He used it simply as a substitute for lime, which is generally of poor quality in Mexico. The manner in which I began the use of the leach was to introduce it into the crushing solution. We were much surprised at the resulting highly increased activity of the crushing solution. I could not account for it on any known chemical grounds at the time, but believed it due to the action of the potassium carbonate upon the large excess of zinc salts present. The above experiment, however, thoroughly explains why some operators find a preliminary treatment with lime beneficial.

To return to the question of economical treatment, I found in the Guanaceví district many rebellious ores which would yield only from 40 to 70% of their silver to plain treatment, and this recovery was not increased even when agitation was carried on indefinitely. The work in question was being done for E. F. Knotts, próprietor of the Anita custom mill, and the successful handling of this class of material meant a profitable increase to his tonnage, apart from the advantage to local mine operators. The process formerly in use at this mill was chloridizing roasting with pan-amalgamation. The idea of using pan-amalgamation in connection with the cyanide process naturally suggested itself, and it was simply a question of how the two could best be combined. It is well known that considerable gold is volatilized in giving an ore a chloridizing roast. Most of the refractory ores in question carried sufficient gold to make such a loss a serious one. Tests were therefore made on the following lines and the resulting extractions proved commercially available: (1) crushing in solution; (2) ordinary cyanide treatment; (3) chloridizing roasting of the residues, with pan-amalgamation.

While an ore must contain sufficient gold or silver to stand the heavier costs of such a combined process, the resulting recovery is surprising and the added cost for the chloridizing roast is not as prohibitive as one might at first believe. The residue discharged from the vacuum-filter should be allowed to dry, as far as is practicable, in the sun, and such drying is quite thorough within a reasonable length of time in the case of a totally slimed ore, containing a large proportion of finely divided crystalline material. Some moisture is beneficial in the subsequent roasting operations, and the net result is the recovery of most of the gold and practically all of the silver. This method answers well for any ore carrying antimony or arsenic, and its availability is simply a question of what sort of treatment cost the ore will stand. It will of course be understood that I am not speaking of copper-bearing ores, but of refractory silver ores, which yield only small percentages of the valuable metals to ordinary treatment. For the less refractory unoxidized ores of the camp, partial concentration, fine grinding, with 24 hours agitation, and a thorough removal of soluble values on the vacuum-filter, was found to answer perfectly.

A study of high-grade samples leads to the conclusion that the readiness with which a silver ore responds to treatment, depends almost wholly upon the mineralogical form in which the silver is present, and, apart from the question of silver locked in particles of galena, the presence or absence of other mineral constituents in the gangue has little or no effect. In confirmation of this view it will be noted that in one and the same sample of ore the gold yielded easily, while the silver proved refractory, and this was true in many different instances.

FEBRUARY COPPER REVIEW

By Misha E. Appelbaum

During the month of February, copper sold at 12½c., and closed at 12⅜c., delivered 30 days basis, for electrolytic, and 12⅝ to 12¾c. for Lake. Business was of a hand-to-mouth nature. The domestic deliveries were slighly better than in January, and the exports were about normal. The production was at a slightly higher rate than during the month of January, with the net result of an increase in stocks of 14,200,000 lb. The consumers were much disappointed that the ratio of production to consumption was not as low or lower than in January, and as a result, they are again keeping up the policy of buying only when absolutely necessary. So long as consumers do not carry any surplus, it is difficult to see how any sustained improvement in price can take place. Considering the general retrenchment in business, and that no decided improvement in business can take place until the Supreme Court's decisions have been announced, the conclusion seems warranted that the metal has held remarkably steady, indicating that when an improvement in business does take place, slightly better prices should prevail. I, however, do not believe that a higher average than 12½ to 12¾c. will be recorded for the present year.

The Grand Canyon of the Colorado river, in Arizona, is 4500 ft. deep on the south side of the canyon opposite Bright Angel canyon. The rim on the north side at the head of Bright Angel is 6000 ft. above the river. This difference is due to a slight dip of the formation toward the south. The distance across the canyon at this place, from rim to rim, is about 14 miles. Yosemite valley could easily be lost in one of the side canyons of the Grand Canyon. There are a few mines in the Grand Canyon region, near Cataract Falls, mostly lead-silver. They are worked in a desultory way by the owners. There are also copper prospects there, these being chiefly on the plateau on both the north and the south sides of the canyon.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Thin Rock-Sections

The Editor:

Sir—Observing the request of 'Inquirer' in your issue of February 4 for information regarding the preparation of thin rock-sections for study under the mieroseope, I submit the following as the result of my own experienee. As I understood him, he has no power apparatus, and must therefore do the work entirely by hand. I had the pleasure of making about 200 slides in this laborious manner and learned a few things which may be of interest to others who are obliged to undertake a similar task. At the outset I will say that if any sort of machine is available, or ean be improvised, upon whieh an emery or carborundum wheel ean be mounted, by all means take advantage of it, as it will save a great deal of time in the preliminary stages of slide making. The essentials of a slide-making outfit are: 1. Several pieces of plate-glass, each about 1¼ in. square. 2. Slips of glass for mounting objeets to be examined under the mieroseope, which come prepared for this purpose, being careful to select those that are not too long, or they will interfere with the rotation of the slide when on the stage of the mieroseope. 3. A supply of eover-glasses used to eover the rock-section after it has been attaehed to the glass-slip. Often these thin eovers are rather hazy in appearance, being coated with some sort of film very difficult to remove. I tried hot and cold water, alcohol, and other things in an effort to elean these eover glasses, but never got satisfaetory results until one day an old German petrographer told me to try dilute acid, sueh as vinegar or dilute nitric acid. I found diluted vinegar to answer the purpose and never had any further trouble with hazy eovers. 4. A small bottle of the best grade of Canada balsam. 5. A pair of good, thin, flat nippers. 6. A dozen or more spring elothes pins. These will be found very convenient, though not absolutely neeessary. 7. A small alcohol lamp. 8. Powdered emery or carborundum, medium coarse and fine grades, the first for cutting and the second for finishing the rock-seetions. A still finer grade of finishing powder will be required for polishing than can be bought, and this ean be obtained by washing the sections from time to time, as the grinding proeeeds, in a small tank of two compartments, the first overflowing into the second. An impalpable powder will be obtained from the bottom of the second compartment whieh may be utilized to polish the roek-sections before mounting. 9. A plate of sheet-lead about ½ in. thiek on whieh to grind the rock chips. 10. A plate of east iron or steel on whieh to finish the grinding. 11. A snitable light-weight geologieal hammer for spalling off chips of rock from hand speeimens. 12. A good store of patienee and perseveranee. With this outfit, after a little experienee and the loss of a few slides, very good rock-sections may be made by using eare. Much time will be saved if suitable thin pieees of the rock to be eut ean be obtained by chipping them from a larger piece with the hammer. This can be done very neatly after a little experienee. Do not select chips for grinding which show too mueh evidenee of having been shattered by the blow from the hammer, for they will break into small fragments before they can be finished and mounted. Some massive rocks, partieularly the softer magnesian kinds, do not readily chip off in thin flakes. With sueh the only way is to grind down a thiek chip. Soft and friable rocks which disintegrate readily should be boiled in Canada balsam before grinding is commeneed. The cooking must be done at a low temperature, otherwise the balsam will become yellow. Canada balsam is naturally a viscous liquid that does not harden readily. Heating it causes a partial evaporation to take plaee, and on eooling it becomes brittle. This property renders it partieularly useful in the preparation of thin rock-seetions.

When a chip has been selected to be ground down, a small quantity of the coarse emery powder, or carborundum, is plaeed with water on the lead sheet. If a lead sheet is not available one of iron will do, but the lead being softer the grains of emery sink into it and the entting proceeds more rapidly than on an iron plate. Plaee the ehip of rock on the plate and holding it firmly with thumb and fingers, scour it around and aronnd, on the face of the plate, keeping the ehip of rock in as nearly a level position as possible or the result will be either more than one faeet, or a rounded surfaee of the chip. The grinding should be carried well over the plate, and not around in a ring, for this would quickly wear a shallow eirenlar channel in the surface of the plate, unfitting it for further serviee. When a fair-sized area has been grounnd off on the under side of the chip, say a spaee ¾ in. square, wash the chip carefully and eontinue the grinding, but now using only the fine powder and on a different plate. If an iron plate only is used, either do the fine grinding on the reverse side of the plate, or carefully wash from it all trace of the eoarse powder, otherwise the rock-section may be spoiled. When the fine grinding and polishing have been completed, as determined by a smooth, almost glassy surface of the rock specimen, wash it with care and dry it over the flame of the lamp. When it is dry, heat one of the pieces of plate-glass, the edges of whieh have been filed or rubbed on a stone to dull them. When it is hot place on its eentre several drops of Canada balsam, using a glass stirring-rod to transfer the balsam from the bottle to the glass plate. Place the polished surfaee of the rock ehip face down upon the balsam and press it down firmly, excluding all air bubbles, and clamp it in position by means of one of the spring elothes pins. The balsam will not harden until it is eold, so either begin grinding another ehip of rock or wait patiently for the first to cool and harden. Remember the balsam will not harden unless it has been gently heated for some time. Some heat the balsam and mold it into sticks for future use. It melts

readily. When the glass is cold and the balsam brittle, the opposite side of the rock chip may be ground in the same manner as before, this being now somewhat easier, as the plate of glass affords a more secure hold upon it. As the grinding proceeds, sooner or later, depending on the character of the rock and the thickness of the chip, the section will begin to appear faintly translucent. With continued grinding this becomes more evident, until a point is reached where care has to be exercised. The slide must then be frequently washed and examined, and toward the end may even be placed for inspection under the microscope to test for transmission of light. A thick slide is never satisfactory, and it requires good judgment to know just when to stop grinding, for a rub or two too many may in an instant destroy the hard work of an hour or more. A few losses of this kind make the operator careful. All grinding, toward the end of the operation, must be done with the fine powder, for if a single grain of coarse powder now scratches the section it is likely to ruin it. Having finished the section, including the polishing, carefully wash and dry it, then gently heat the thick glass plate to which the chip is attached. Meanwhile heat one of the glass slips upon which to mount the rock-section. When hot place on it two or three drops of balsam and then, with great care, gently move the thin section from the thick to the thin glass plate, using the blade of a pocket knife, pushing carefully sideways. If the rock section does not move readily it is too cold and must be made hotter. When it slides off easily deposit it upon the drops of hot balsam on the glass slip and press it down gently but firmly upon the glass. The balsam will ooze out from under the edges of the rock-section, but this does not matter. Care must be taken to exclude all air bubbles, at this time. Heating the glass slip too hot will cause the balsam to boil, creating air bubbles between the rock-section and the glass. This is always to be carefully avoided. When the rock-section has been well set on the glass slip, let a drop or two of balsam fall upon it and immediately cover with one of the thin glass covers, pressing it down and again being careful to exclude air bubbles. I prefer square cover-glasses, though some like round ones. If the slide be too hot to use the fingers, press the cover-glass down with a small cork. Clamp the finished slide with a spring-pin, using one having not too strong a spring or it may break the frail cover-glass. Allow it to cool thoroughly. When cold scrape off the excess balsam with a knife blade, wash carefully with alcohol, rub dry and clean. The slide is now finished and ready for the microscope. Although slides may be prepared much more rapidly by machinery, they are no better than those made in the manner here described, for the finishing—the fine touches—has to be done by hand, anyway, to get the best results. Slide-making is laborious and painstaking work, but it is full of interest from beginning to end, and the laborer feels well paid for his work if he gets a good slide.

WILLIAM H. STORMS.

Berkeley, California, February 8.

Inquartation of Assay Buttons

The Editor:

Sir—In the correct assaying of many gold ores, an addition of silver is required, either in the crucible or to the lead button before cupellation. The object of this is to serve as a collector of the gold to prevent the loss of the otherwise minute button in cracks formed in the cupel, to so dilute the gold that the cupel loss may bear a comparatively small proportion to the gold sought, and to indicate the possible presence of tellurium. Where the silver present in the ore is also required, this silver addition necessitates a separate assay for that purpose. Various methods have been proposed to make this silver addition so accurate that a correction could be made for it, and the extra assay and frequent re-assays required because of the accidents which occur in handling small buttons might be done away with.

The use of solutions of silver has not proved satisfactory in my experience. With the concentration permissible, sufficiently close measurements are not possible, and frequently some of the solution is absorbed by the crucible before reduction. Alloys have not been successful, owing to the irregularities caused by liquation. I have not found punching silver foil accurate enough for the purpose, but have finally succeeded in getting close results by using silver wire. This is of uniform density and may be drawn to any required degree of fineness. There are various methods of cutting this regularly; for example, by winding around a knife-blade of uniform width and cutting carefully along the edge, or by using a glass rod and cutting along a line. The various pieces check close enough for ordinary work, or they may be arranged in classes of equal value.

I have devised a simple cutter (which I hope to perfect), that cuts 20-gauge wire into pellets weighing 35 mg. which do not vary over 0.05 mg. and which could be sold at a good profit at less than fifty cents per hundred pellets. It can be seen that this method adds to the accurracy of the assay, lessens the cost, and increases the output. A blank assay is run with a pellet, and the resultant button flattened and used as a counterpoise with other assays using similar pellets. This pellet is used with the weights and the reading of the weights taken, ignoring its value. The cupel loss is automatically corrected, and two crucibles may be made to serve as a control for both gold and silver.

GEO. A. JAMES.

San Francisco, March 4.

Natural ventilation in mines in some regions is noticeably affected by atmospheric conditions, particularly where the difference in elevation between the two or more entries to the underground workings is small. This condition has been frequently observed in the Cripple Creek district. On some days there, when the barometer is low, the ventilation of the mines is very poor unless artificial air currents are created by fans or blowers.

LONDON

The Oroville Dredging Co.—Pato Mines, Ltd. — Oroville Exploration. —Half-Yearly Reports of Cornish Tin Mines.

The official news about dredging operations at Oroville, California, is more readily obtainable in London than on the spot, though the information published here is not at all up-to-date. It will be remembered that the Oroville Dredging Co. was formed in America in 1905, to consolidate a number of gold-dredging companies operating in California. As a large proportion of the shares were held in England, a new company was formed under English law in June 1909 to acquire the shares of the American company and eventually to take over the direct management of the properties. The English company has now issued a report covering the period from its incorporation in June 1909 to September 30, 1910. This shows that the exchange of shares is not yet complete, as several American holders have not yet sent consent, and consequently the American company is still continuing in existence and acting as owner and manager of the properties. Accompanying the report of the English company is the report of the American company for the year ended July 31, 1910. Shortly after the incorporation of the English company, the Pato gravel mine on the Nechi river, Colombia, was acquired, and a subsidiary called the Pato Mines (Colombia) Ltd. formed in England with a capital of £100,000 to work it. The purchase price paid to the owners of the property was 25,001 shares, and £11,000 in cash, and 74,993 shares were allotted to the American company as purchase consideration. The working capital for the Pato Mines was to be provided by the issue of debentures, but owing to the opposition of the owners of the Pato property, 8% income notes are being issued instead. The money is being provided out of the profits of the American company and the notes are to be redeemed by the allocation of 75% of the net profits of the Pato company every year. Up to December 31, the American company has advanced $271,017, and probably the whole amount required will be about £100,000. It is estimated that the Pato property will before long be making £40,000 per year profit. During the time that this financing of the Pato mine is being done the Oroville companies are paying no dividends. The report of the American Oroville company for the year ended July 31, shows that at the four properties, 5,661,612 cu. yd. of gravel yielded gold worth $561,569, with a net profit of $275,452. The Oroville Exploration was the largest and most profitable producer, the amount handled being 2,885,074 cu. yd., the production $317,270, and the profit $199,168. The extraction per cubic yard was 11c. and the cost 1.09c The Bear River property, as before, has been worked at a loss. The area left for the three profitable companies to work is sufficient for six years operations. The Bear River ground is not included in the estimate, though W. P. Hammon, the manager, considers that the advances made in dredge design will make this tract profitable later on

A batch of half-yearly reports of Cornish tin-mining companies have been issued this week. The report of Dolcoath for the second half of 1910 shows that 44,659 tons of ore was raised and treated, yielding 878 tons of concentrate, which sold for £85,819. The yield per ton was 44 lb., and the average price received per ton of concentrate was £97 15s. or 38s. 5d. per ton of ore. The amount of ore treated was 2620 tons less than in the previous half-year, the reason being that 60 of the old stamps have been dismantled. It is expected that 8 of the 12 new Holman air-cushion stamps will start work this month. The decrease in ore treated was more than compensated by a rise of 3.63 lb. per ton in the extraction and by the increase of £9 1s. in the average price obtained. The total receipts for the half-year were £87,043, the working costs £56,807, and lord's royalties £5721, leaving a profit of £24,515, as compared with £13,018 during the previous half-year. The dividends of 9d. declared in December and 6d. now announced absorb £21,500, and £3449 has been written off for depreciation. The continued high price of tin makes the present situation most satisfactory. The new main shaft has been sunk to 3000 ft., the present intended depth, and the pump stations have been finished. A cross-cut has been driven southward to cut the main lode and the equipment of the shaft with rail guides is now in hand. It is expected that everything will be ready by the middle of May. An analysis of the accounts shows that the cost of working was 25s. 5d. per ton, or 28s. per ton including lord's royalties. The report of Carn Brea & Tincroft for the same half-yearly period shows that the receipts and expenditures have practically balanced. This compares with losses of several thousand pounds during the last two or three years. The amount of ore raised was 38,892 tons, and 473 tons of tin concentrate was produced. This was an extraction of 27¼ lb. per ton, which is 3 lb. less than the average during the previous three years. The average price obtained was £82, the highest price since 1907; the total amount received was £38,930 and the receipts per ton of ore 20s. In addition, £2202 was received from the sale of copper, arsenic, and wolfram concentrates. The working cost was £40,689, to which is added £1507 for lord's royalties, the net result for the half-year's work being a profit of £13. In recording the progress of this company six months ago I described at considerable length the old method of mining and concentration and quoted R. Arthur Thomas' report on the subject, together with his recommendations. I then recorded that Viscount Clifden, one of the lords, had undertaken to provide a magnetic separator for the better treatment of the ore found at North Tincroft. This plant is now in place and should be at work by the time this notice is published. The other lord, Mr. Basset, has undertaken to contribute to the cost of certain development work, up to a sum equal to his royalties during two years. The managers give details of underground developments, but have no important discoveries to announce. The capital funds of the company are running low, but it is hoped by reason of the present high price of tin and of the improved dressing methods to accumulate a working surplus during the current year, so that it may not be necessary after all to reconstruct. Perhaps the report of the Grenville company is the most interesting, for it shows that the new manager is trying to break away from the time honored practice, almost universal in Cornwall, of buying mine supplies from individual directors or shareholders. Cornishmen know only too well that mining in that county is a sort of family party, and that timber, machinery, etc., are bought without any public competition, but from people interested in or controlling operations in the mine. In addition, there is no real competition for the sale of the tin concentrate, and less is received than would be the case if the concentrate were sold to Germany. The consequence is that the cost is too high and the income too low. Though the community may benefit by this family arrangement, the shareholders, as shareholders, do not get much return. Take the case of most of the companies working near Camborne and ask where they buy timber; the answer is, from Mr. Harvey, our chairman; where do they buy machinery and drills? From Mr. Holman, a director. To whom do they sell their tin concentrate? To Mr. Pearce, Mr. Bolitho, Mr. Bain, or Mr. Lanyon, any of whom may be on the board. Far be it from me to say that this system is carried out in an immoral way, or that the community is treated badly by it; but it is obvious that the system does not allow the manager a free hand in beating down the sellers of supplies for the benefit of his mine. The fact that Mr. Battens has decided to advertise his requirements in the way of supplies is sufficiently remarkable to warrant special notice. However, to return to the Grenville: The mine is situated to the south of Camborne and has been worked for many years under the old cost-book system. The company was reorganized under limited liability in July 1906. The ore is fairly clean, containing little wolfram or pyrite, so that the concentrate brings a good average price. The mining and metallurgical equipment is of the old Cornish

type. The report for the half-year ended December 31 shows that 21,047 tons of ore was raised and 298 tons of concentrate sold, being an extraction of 32¾ lb. per ton. The price received was £29,485 or £99 per ton, a figure which, when compared with that of Carn Brea & Tincroft, shows the high quality of the concentrate. The balance of profit, after paying £1077 as lord's royalty, was £4308. The half-year began with a debit balance of £10,465 and ends with one of £6157. During the period under review the heavy rain has caused serious flooding in the lower levels, and it has not been possible to gain access to the best ore. The water-level is, however, being lowered again. Mr. Battens is strengthening the pumps with the object of combating the water in a more efficient manner. He also reports that he has inaugurated a better method of sampling, so that less low-grade ore and waste is now being mined.

NEW YORK

Report of Copper Producers.—Comment on Copper Situation.—Cessation of Mexican Investments.—Adverse Market Factors.—The Calumet & Hecla Merger.—Hedley Gold M. Co.—Profits of Federal Co.—United Rico.

The report of the Copper Producers' Association, covering the month of February, shows an increase in copper stocks of 14,198,280 lb., which, with the January increase of approximately twenty million pounds, makes a total of 34,000,000 lb. gain since the first of the year. But for the fact that domestic deliveries increased during the short month the showing would have been even more unfavorable. Domestic consumers took 50,518,998 lb. in February, as against a home consumption in January of 42,078,557 lb. The anticipated completion of equipment for the new copper properties has been much talked about during the last year, and pride taken in the magnitude of those mines and their probable production. Now nothing is heard of the first results at the Ray Consolidated, and the Miami, where the first units of the concentrating plants are being started. It is not strange that, in the face of prevailing conditions, the copper-share market should have few followers, nor that a huge output should no longer be considered a good argument in favor of any specific copper issue. It is not alone North American porphyries that are to be considered, as production in other parts of the world is on the increase. J. B. Haggin's Cerro de Pasco mine in Peru has cost a large amount of money, but it will now become a factor in the metal market, with a possible production of approximately seventy million pounds of copper per annum. Australia's output is not large, but it is increasing; the copper mines of Africa have figured mostly so far as stalking-horses, but in due time they, too, will be turning out copper. All of which is good argument for the consumer and held to be ample reason for the adoption of the present policy of allowing the producers to carry the burden of all of the metal up to the moment it goes into mill or factory. While copper for a year or more has been the centre of public interest in the East, there has been for a long time a constantly growing investment in Mexico. Just what the present situation means is not known. The order for the massing of troops along the Rio Grande, and the assembling of the fleet off the Gulf coast, may or may not mean a grave crisis in Mexican affairs, but it does mean cessation of investment for the time being. One well known promoter of mining enterprises, who has been connected with several successful Mexican mines, remarked that there were several thousand poorly financed and worse managed Mexican companies that would welcome a serious revolution, as it would give the managers an excuse to quit. It is probable that many an investor, following up his money, will hear the story that the revolution stopped all operations.

The unsatisfactory conditions prevailing in the outside market in New York is causing many of the more important mining issues to seek admission to the Exchanges. Ray Consolidated and Chino are trying to satisfy the listing committee of the New York Stock Exchange; Tuolumne Copper, Mason Valley, and Inspiration have been admitted to the Boston Stock Exchange, and other important issues are to follow, especially if the listing committee of the New York Stock Exchange can be induced to extend any privileges to companies whose properties have not reached the producing stage. The market has so many adverse factors to contend against just now that it can not be expected to make progress. The possibilities of trouble in Mexico are doubtless magnified, but the uncertainty is enough to drive traders from the market; add to this the special session of Congress with tariff revision almost a certainty; the recent decision of the Interstate Commerce Commission is not now considered so drastic, but it has strengthened the impression that the coming decisions by the United States Supreme Court will be radically against the corporations. Thus it is not surprising that the market should register low prices for the year, and that trading should fall to almost nothing. The Calumet & Hecla consolidation has not been abandoned, as it was reported it would be when it was made apparent that obstructive litigation would be begun. Inasmuch as temporary restraining orders have been issued by the Federal Court in Michigan, the Calumet & Hecla management has resorted to the expedient of informal action by the various companies. At a meeting held this week for the purpose in Boston, the Calumet & Hecla shareholders, representing over three-fourths of the issued stock, voted unanimously in favor of the proposed merger. The Allouez meeting was held on the same day and resulted in a safe majority in favor of the merger. While these expressions of opinion are not binding and the votes will all have to be taken again, the record of such action will be the strongest argument in Court, and undoubtedly will be used to show that the dissenters are a small minority. The stockholders of the Ahmeek, Centennial, Superior, and Tamarack are now all informally recorded in favor of the merger by majorities that make such action practically unanimous. That part of the public that cares to do so is now able to get the inside history of the career of Union Copper, in which Walter George Newman was a specialist for a long time and which was used as the vehicle of more than one picturesque coup by Newman. The story is being told in the bankruptcy proceedings of Sig. H. Rosenblatt & Co. One of the chief parties in interest in Union Copper is James H. Phillips, Jr., of the Nevada Consolidated.

The Hedley Gold Mining Co. makes a satisfactory annual report for 1910, showing gross earnings of $519,356; expense, $255,370; net, $263,986, which is equal to nearly 23% upon the issued capital of $1,200,000. The Hedley company operates what is known as the Nickel Plate mine and mill, situated in the Yale district, in Hope mountains of British Columbia. It is paying 3% quarterly and the last distribution just declared is increased by a 2% extra disbursement. The Federal Mining & Smelting Co. has been the centre of some market activity recently, and shareholders have been taking more interest, owing to increased earnings; the past quarter shows a profit of $345,000, which, after deducting the dividend on the preferred, leaves a surplus equal to 9% per annum on the common. The reorganization committee of the United Rico Mines Co., of Rico, Colorado, is extending the time for the deposit of bonds and stocks under the reorganization plan. This company was floated in the East by a New York Stock Exchange house and there are a good many grievances owing to the failure of the company's operations to produce any profit, and the apparent abandonment of the concern by the interests at one time most prominent in it. Another example of the interlacing of copper interests is to be noted in the possible absorption of the United Metals Selling Co. by the Amalgamated Copper Co. This move will make Amalgamated the largest holder in the International Smelting & Refining Co., as the United Metals owns 40,000 of the 100,000 shares of International Smelting & Refining outstanding. The Arizona Copper Co. is to issue debentures for £200,000 to finance the rehabilitation of the plant. Recent development work is said to have developed some smelting ore sampling as high as 7% copper.

SALT LAKE, UTAH

Two Lead Furnaces Being Installed at International Smelter.—Operations of Bingham Mines Co. — Notes on Park City and Tintic.

Definite announcement is made that the International S. & R. Co. will install two furnaces, each of 500 tons capacity, for the treatment of lead ores. The outlay will be $500,000, and about 100 men will be added to the force. Work on the new furnaces will commence at once, so that the plant will be ready to treat ores of this class as soon as possible, and the purchasing of lead-bearing ores will be commenced when the bins are ready for them. Only Utah ores will be sought at first, but the field will be extended and the plant enlarged as occasion requires. The annual report of the Commercial mine, operated by the Bingham Mines Co., shows a profit for 1910 of $65,902, about $10,000 more than in 1909. The earnings would have been greater but for the fact that the company was obliged to move all of its surface buildings last fall and drive another tunnel through which to work. This was due to the fact that the Utah Copper Co. acquired

Map of Utah.

the old tunnel site and needed it for dumping purposes. The new tunnel gives greater depth, with a correspondingly less distance to hoist ore and pump water, so eventually the Commercial will be the gainer. The Dalton and Lark mines, also part of the Bingham Mines Co. holdings, made an increase in production and earnings, 12,536 tons of ore having been produced, of a value of $153,047. The total production of the two mines was: gold, 2140 oz.; silver, 169,974 oz.; copper, 1,031,241 lb.; lead, 3,411,499 lb. Treasury balance of the company is $124,000. By a decision of the Secretary of the Interior, the Nemesis claim, owned by E. A. Wall, has been canceled. Patent on this claim was applied for over eight years ago and contested by the United States S. R. & M. Co. The first decision eliminated all but less than an acre of the Nemesis, and on an appeal it is decided that this is also overlapped by locations of the United States company.

The annual report of the Daly-Judge shows that during the past year the net profits were $94,177, and the cash balance January 1, $316,215. Included in the disbursements was an item of $36,000 as advance rental on the Ontario tunnel for three years which was required by the contract. This item will not appear again until three years after the Daly-Judge extension of the tunnel is completed, so that actual profits were $130,000. Production for the year was 1253.19 oz. gold, 633,539 oz. silver, 10,755,841 lb. lead, 9,880,525 lb. zinc, 393,170 lb. copper, which were sold for $552,100.80. The drift from the Ontario tunnel, which is being driven to the Thompson-Quincy, is within 150 ft. of the latter's side-lines, and within another two months this company should be getting the benefits of it. Ernest Bamberger has resigned as general manager of the Daly West, and has been succeeded by H. G. McMillan, who has been a director of the company for some time.

The stockholders of the Tintic Empire, Tintic Combination, and Bullock have ratified the agreement entered into by the boards of directors to consolidate the three companies as the United Tintic Mines. The new company will be capitalized for 2,000,000 shares, half of which is to remain in the treasury and the other half is to be exchanged for old stock, share for share. The consolidated property comprises 28 claims along the Bullock and Aspinwall veins. Operators of the Knight mines have made a contract with the A. S. & R. Co. to supply a minimum of 250 tons of ore per day. They have also a 70-ton contract with the International, so that they will be required to mine and ship 10,000 tons per month. Most of the increased tonnage will come from the Iron Blossom. Directors of the Uncle Sam have declared a quarterly dividend of 5c. per share, amounting to $25,000, the same as last quarter. Beck Tunnel operators have tapped the orebody of the Uncle Sam, 12 ft. above where the latter found it, and have followed it south along the line which has been agreed upon between the two properties for 125 ft. The body is 12 ft. thick and 50 ft. wide at this point. The orebody found on the 1050-ft. level of the Victoria is proving better than was expected. Two carloads have been shipped, but smelter returns have not been received. The Colorado made a shipment recently of one 40-ton carload which brought $25,000. The week's shipments from Tintic mines amounted to 171 carloads, and for the first time in months Centennial-Eureka did not head the list, Iron Blossom shipping 43 cars and Centennial-Eureka 37. The Union Chief at Santaquin has commenced shipping, having sent out a 35-ton carload which netted $1000.

BUTTE, MONTANA

Boston & Montana Co. Dissolved. — The Crescent at Philipsburg. — Tendency to Reopen Idle Mines. — The Conrey Placers. — Anaconda Co. Buys Lime Quarries.—Litigation.

The Boston & Montana Con. Copper & Silver M. Co. has been dissolved in accordance with the application made to the District Court by the directors of the company. This action was taken by direction of the stockholders December 27 last, as a result of the property having been sold to the Anaconda Copper M. Co., under the terms of the merger agreement, for 1,200,000 shares of Anaconda company stock. Soon after the application for dissolution was made, one Louis Seasongood, of Cincinnati, sent a notice to the clerk of the district court in this city, saying that as the holder of 25 shares of stock he was opposed to the dissolution and proposed to fight the same. In consequence of Mr. Seasongood's statement, the hearing of the application was continued for a week, and under the court's order a notice was sent to him. Instead of coming in person to the hearing or engaging an attorney, he wrote another letter asking for a further continuance for two weeks. This was deemed unfair, and was opposed by the representative of the Boston & Montana company, the court taking the same view. Evidence was accordingly heard as to the indebtedness of the company having been discharged, and the fact that the property had been transferred to the Anaconda company, after which the court issued an order dissolving the corporation.

While conditions are not favorable to the starting of new mining enterprises, there is a tendency all over the State to revive mining properties which have been idle for many years, showing a good degree of confidence in the future. In some cases such properties have ore of good grade, but the method of treatment is antiquated.

With the adoption of modern methods, good results can be achieved. In Madison county many owners of claims in Alder Gulch district refused to dispose of their interests, declaring that they are going to install new machinery and work the properties themselves. In this district it is reported that there are 10 to 12 claims which have not been worked for 12 to 15 years on which there will be activity next spring and summer. In Ruby valley, where the Conrey Placer company has been operating three dredges all winter, the fourth dredge will be started in the course of the next three weeks. The company has planned for extensive work this season. The Granite-Bimetallic company, operating near Philipsburg, has recently finished a 4-mile ditch to carry water from Stony lake to its placer and sapphire ground. Other placer miners are working along the tributaries of Rock creek. Indications are that the season will be prosperous in Granite county. In the Georgetown district, south of Anaconda, the probability is that no properties will be idle in the course of another month, a condition of affairs which has not existed for many years. Chicago capital has been invested in the Crescent company property, on Stony creek, near Philipsburg, and a season of activity is anticipated. The 10-stamp mill, connected with the mine, has been started, and as soon as the addition to the building is completed, ten more stamps will be crushing ore. The machinery is all on the ground. There are sixteen claims in the group, but the greater part of the work is being done on the Trenton, and in this claim alone there is said to be enough ore to keep the 20-stamp mill operating for several years. The property is developed by 4700 feet of adits. Ore treatment in the cyanide plant is successful, and material for several more tanks has been ordered. The Pilot Butte Mining Co., organized by people of Milwaukee, St. Paul, and this city, has taken over the Pilot Butte claim and expects to begin operation in about three weeks. Machinery ordered is being placed in position. This claim is surrounded by producing properties, such as the Badger State, the Elm Orlu, the Black Rock of the Butte & Superior company, and the Berlin of the North Butte company. There is a belief that the claim contains the Berlin vein and also an extension of the copper vein now being developed by the Badger State. The Pilot Butte has a 3-compartment shaft, 530 ft. deep, and it is proposed to sink till 1000 ft. depth has been reached. An effort is being made with the Butte & Superior company to arrange to run a cross-cut from the 1200-ft. level of the Black Rock shaft. This will provide a means of ventilation for both properties. The Anaconda company hereafter will supply its own fluxing material for the Great Falls smelter. It recently purchased the lime-quarries of W. H. Albright for the sum of $100,000. The ground secured consists of 1500 acres and does not include the water rights, nor gypsum deposits. The Great Falls smelter requires about 600 tons of limestone daily.

The Court of Appeals of San Francisco, in handing down its decision in favor of the Anaconda Copper Mining Co. against the Deer Lodge ranchers, gave the latter a chance to bring the case before the United States court by means of a writ of review, and one of the attorneys for the ranchers says that the opportunity will be embraced. The ranchers alleged in their case, which was heard before a Master in Chancery appointed by Judge William H. Hunt, that the smoke and poisonous gases emitted from the big stack of the Washoe smelter killed their vegetables and grasses and poisoned their cattle. After Judge Hunt had gone over a transcript of the evidence he gave his decision in favor of the Anaconda company and the case was taken on appeal, with the result as stated above. The Deer Lodge ranchers sought to close down the smelter, and this would have had the effect of throwing thousands of men out of work and the closing down of the greater number of mines in this city.

The Butte & Ballaklava company has filed its answer to the suit of the Anaconda company for $750,000, the value of ore alleged to have been extracted from ground belonging to the latter company. In the answer the Butte & Ballaklava company asserts that no location of the Right Bower claim was ever made, nor was any notice or location of the same verified by law ever filed, until long after December 15, 1879, at which time the notice of location of the Ballaklava claim was filed, and that the location notice of the Right Bower claim placed on record was wholly void for the reason that it was not made on oath, and that the oath of verification affixed thereto did not recite or aver the truth of the matters set forth in the notice or declaratory statement. It is further set forth in the answer that the patent to the Right Bower claim was not issued until long after December 15, 1879. The Butte & Ballaklava company maintains that by reason of prior location, even if the Right Bower vein unites with the Ballaklava vein at depth, the apex is in the Ballaklava claim and that the Ballaklava company is the owner of all ores in such veins below the point of union as against any claims thereto that may be asserted on the part of the plaintiff or any owner of the Right Bower claim. It is denied that the Mountain Chief vein is disclosed on any level of the Ballaklava mine below the 500-ft. level, or that the said vein is disclosed in any workings from the Ballaklava company's shaft to which the plaintiff has not been able to obtain access. It is further denied that the Mountain Chief vein continues on its dip in a general southwesterly direction, or that it so far departs from a perpendicular as to extend through the south sideline of the Mountain Chief lode claim, or into or beneath the Ballaklava lode claim. It is admitted that there is a vein in the Right Bower claim and that in its dip it is carried through the Mountain Chief claim. It is denied that ore has been extracted from the Mountain Chief or Right Bower in excess of $750,000 or in any amount greater than $150,000. It is also asserted that the Anaconda company extracted ore from the Ballaklava lode claim to the value of $864,130 and asks for judgment on this amount.

JOHANNESBURG, TRANSVAAL

The Premier Diamond Co. — Transvaal's Gold Output for January. — The Rand Mines and their January Production.—City Deep Mine. —Mine Earnings.—Tin Mining.

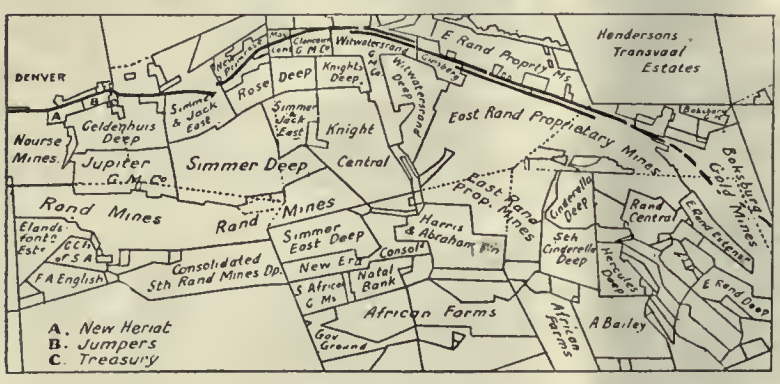
An advance copy of the eighth annual report of the Premier (Transvaal) Diamond Mining Co., Ltd., has just been issued. The significant features of the statement now submitted to shareholders in this, the second largest diamond mining company in the world, are (1) a much larger scale of operations as compared with the previous year, and (2) an improved selling price for the company's product. As regards the enlarged scale of operations, it is important to note that the material handled was increased by 2,253,565 loads as compared with that of the preceding year. The directors state that the average price realized per carat improved from 12s. 6.29d. to 13s. 11.39d. during the year. Furthermore, it is stated on authority of the general manager in London that "the prospects of a good and sound business during the coming year are very bright indeed." In commenting on the results secured during the year, which have yielded a profit of £541,191 13s. 7d., or £102,380 13s. more than in the preceding year, the directors state "the scarcity of labor has not yet been overcome and is consequently a cause of much anxiety to your directors. Every endeavor is being made to raise the labor force to at least the minimum required for operating the whole plant, now complete, and thus insure the best results. Experience has shown that a deficiency in labor must be reckoned with at one time or another during every year, and it is now a serious problem to minimize this risk." A large amount of development was carried out in the mine during the year. The Premier pipe has now been worked down to an average depth of 125 ft. The fifth level has been opened at a depth of 210 ft., and the material above this level represents 20,000,000 loads. Among the many interesting features contained in the report of W. McHardy, general manager for the

company, mention may be made of the equipment of the mine with search-lights in place of the arc lamps previously employed, and which were damaged by blasting operations. In huge open-workings, such as that of the Premier mine, search-lights erected on the edge of the pipe would appear to be almost ideal for lighting purposes and for the detection of theft. At the Premier they have proved satisfactory, both as to efficiency and economy, and it has been decided to complete the equipment of the mine in this respect by the installation of five additional search-lights.

The gold output of the Transvaal for January has been declared at 651,027 oz. of fine gold, of the value of £2,765,386. This compares with an output of 640,995 oz., valued at £2,722,775 announced as the result of the previous month's operations. The increase amounts, therefore, to 10,032 oz., or £42,611, but falls about £9000 below the Transvaal's production for October 1910. In January the Witwatersrand contributed £2,658,338 to the total, outside districts (Lydenburg, Barberton, Klerksdorp, and Heidelberg) producing £107,048. The leading productive mines on the Rand last month are given below, with output of each mine:

Mine.	Locality.	Output.
East Rand Proprietary Mines.	East Rand	£254,201
Crown Mines	Central Rand	223,193
Randfontein South	West Rand	132,172
Robinson	Central Rand	113,475
Geldenhuis Deep	East-Central Rand..	96,024
Simmer & Jack	East-Central Rand..	89,190

Among the features of last month's production is the declaration of an output of 3576 oz., worth £15,190, by the City Deep mine, the great Eckstein-Wernher-Beit deep-level which is assured of becoming one of the leading gold producers of the world at a comparatively early date.



Part of the East Rand.

This is the City Deep's initial declaration, and it affords, of course, no reliable criterion as to the productive potentiality of the company, since the first crushing operations have been attended by the disadvantages incidental to the starting of a large plant. A considerable amount of gold has, of course, been absorbed in the setting of the plates and is in circulation in the cyanide plant. Furthermore, the quantity and efficiency of the native labor employed has left much to be desired, and at the outset of productive operations trouble was experienced with the balance-ropes. These matters are being adjusted, and the City Deep company may be expected to record large outputs. The profits of the leading mines for last month are as follows: Crown Mines, £104,000; East Rand Proprietary, £103,058; Robinson, £78,050; Simmer & Jack, £49,873; Village Main Reef, £39,313; Ferreira Deep, £33,650. The above does not include any of the profits earned by the Randfontein mines, for which figures are not, at the moment of writing, available.

The improved prices for tin prevailing in Europe and America have quickened interest in tin mining in South Africa, and a feature of the Johannesburg Stock Exchange dealings during the past fortnight has been the activity displayed in connection with Transvaal and Swazieland tin stocks, particularly with regard to the Zaaiplaats and Swanzie tin companies. The output of the former for last month was 162 tons of 70% concentrate, and it is understood that a wealthy London and Johannesburg mining house is negotiating for the acquisition of a substantial interest in the company. The question of erecting smelting works in the Transvaal province to treat the products of the various mines now declaring outputs has again come up for consideration, but the consensus of opinion at present appears to be that, for the time being, the project is premature. The gold output of the Witwatersrand for the current year is likely to mark a big advance over that for 1910. In addition to the City Deep, two or three other big new producers will be adding their quotas to the 1911 output. For instance, the Randfontein Central Co. has just started 300 of the 600 stamps erected on the property, and the new mill of the Brakpan Mines Co., which will have a capacity of 60,000 tons per month, is rapidly nearing completion.

HOUGHTON, MICHIGAN

Cost of Mining and Milling Native Copper Ores.—What to Include in Operating Costs. — Tonnage Costs and Costs of Finished Copper.

The Calumet & Hecla management is credited, in the press, with an ambition to reach the basis of 'dollar rock.' By this figure is meant a total cost of mining and milling ore carrying native copper of $1 per short ton. This figure never has been reached in the Lake Superior district, and although costs have been decreasing almost since the beginning of mining operations, nearly seventy years ago, much further progress must be made before dollar rock is reached by any mine in this district. All of the leading mines show substantial reductions in operating costs, per ton of ore stamped, during the past decade. The pioneer of the field in low tonnage-cost was the old Delaware mine in Keweenaw county, working a conglomerate bed supposed to be a northern extension of either the Allouez or conglomerate lodes of Houghton county, which, nearly thirty years ago, mined and stamped its ore at a cost of $1.27 per ton, under the management of Charles H. Palmer, a veteran miner, who is still active, though in other fields. The Delaware was unsuccessful, however, because of the exceedingly low average content of copper. Some twenty years ago the Atlantic mine managed to get its costs under $1.50 per ton, and eventually reached about $1.30 per ton. None of the other mines of the district are yet as low as the Atlantic was before it was ruined four years ago through air-blasts. The matter of tonnage costs, while of supreme importance, is complicated by a variety of prime factors. The first of these to come up for consideration is the matter of development costs. It was the habit of the mine managements, except the Calumet & Hecla, in the early days and until a comparatively recent period, to carry a construction account, to which was charged all extraordinary expenses, such as new shafts, machinery, equipment, and general surface improvements, beyond ordinary repairs. By reason of this convenient construction account, which proved a catch-all for miscellaneous costs, it was possible for many mines that actually were losing money, to figure out annual profits on production, and great was the grief of confiding shareholders, after years of such paper profits, to be faced with the necessity of further assessments, absolutely imperative for financing operations. The construction account enjoys less favor than formerly, but it is obvious that the matter of unusual development and construction costs must be taken into consideration in arriving at a just estimate, not only of present costs, but of future possibilities. For instance, the Ahmeek mine, which is one of the best new mines in the district, showed a cost of almost 15½c. per pound for finished copper, and as the average price for which the metal was sold that year

was only 13.37c. per pound, the year's results, on their face, were most unsatisfactory; but, as a matter of fact, the high cost was due to charging directly to operating expenses very large sums required for sinking new shafts which were not productive, adding new hoists and general machinery equipment, building, constructing, and equipping a new mill, and adding a great deal of miscellaneous building. While a considerable amount of outlay is required every year for construction work, including the various items of new shafts, new machinery, new buildings, and remodeling of mining and milling plants, it is obvious that this should be charged direct to operating costs, as such construction expense is a continuing charge. The difficulty in this case lies in striking a fair average, as construction costs necessarily are much heavier in some years than others, at the old mines. In the case of the new mines, such as Ahmeek, having everything to provide, at the start, construction costs necessarily are exceedingly high, but as these provide permanent equipment, allowance must be made for the unduly high cost of finished copper, when including the heavy expenditures required to open and equip the mines.

'Dollar rock' would mean much to the Lake Superior district, as with copper at 12½c. per pound, it would permit a developed and equipped mine to make expenses on copper-bearing ore averaging a net mill-run of only about 10 lb. of blister copper per ton of ore stamped. That 'dollar rock' may be reached eventually, by some of the mines more favorably situated for cheap tonnage costs, it is reasonable to infer, from the steady reduction in figures of costs, per ton of rock, that has been effected since the beginning of mining work in this district. The cost of mining and milling, per ton of ore, necessarily varies from the cost of finished copper per pound. In the case of the old Atlantic mine, before referred to, tonnage costs were low, but finished copper costs were high. Tonnage costs were low because the Atlantic ash-bed, of about 15 ft. average width, was mined from wall to wall and the entire product stamped, without selection, while finished copper costs were high because the ash-bed averaged a return of only about 13½ lb. of copper per ton of ore stamped. It is obvious that a low-grade mine, having a wide bed, can secure cheap costs per ton of ore, but will be unable to make cheap copper, while a mine having a narrow bed or vein, like the branch vein of the Michigan mine, can make cheap copper, though at high costs per ton of ore stamped. Up to and including the production of 'mineral,' which is the native copper with gangue rock adhering that is produced at the mills, one mine can produce copper about as cheaply as another, making necessary allowances for width of lode, depth of workings, and difference in cost between amygdaloidal and conglomerate beds, in both mining and milling, owing to the more refractory nature of the conglomerate, but thenceforward the costs vary according to the amount of copper recovered. It costs little more, if any, to mine and mill a ton of ore from a rich bed than a ton of ore from a lean bed. In fact, the Baltic and Champion mines of the Copper range probably are able to mine and mill a ton of ore cheaper, on the average, than one can be mined and milled from the Isle Royale mine, only a few miles distant, for the reason that the Baltic lode of the Baltic and Champion mines is considerably wider than the Isle Royale and Portage beds of the Isle Royale mine. From the point of milling onward to the production of finished copper, the Champion and Baltic mines show much higher costs, for the reason that their bed carries 75 to 100% more copper than the beds of the Isle Royale mine, and costs of smelting, freight, insurance, and commissions on sales are fairly constant factors. The cost of preliminary crushing, done in 'rock-houses' at the mines, is 4 to 6 cents per ton, in the case of mines having modern equipments, and much higher with some of the small mines having poor crushing plants. The cost of final crushing at the stamp-mills has been reduced largely from the inception of milling, and within the last 15 years has been practically cut one-half at the best mills.

General Mining News

ALASKA

Reports from Seattle show that all steamships bound for southern and southeastern Alaska are carrying hundreds of prospectors, miners, and tradesmen to such ports as Cordova, Valdez, Seward, and Skagway, and from those places the travelers will make their way over the snow and ice trails to interior points before such trails and streams become impassable with the opening of spring. Many of those going in early are men who have been in the country before, and most of them are going to the Tanana, Innoko, the upper Kuskokwim, the Yukon, and their tributaries, including the Koyukuk. There is no stampede to Alaska, but the indications are that the travel thither during the next four or five months will quadruple that of 1910. Quartz mining in that country is receiving an impetus, this being especially true of the Fairbanks region, Valdez, and the Copper River country; and there is to be more than the usual activity in the regions tributary to Juneau and Ketchikan. The diggings in the Innoko and Kuskokwim basins, however, will be confined to placer beds. Stores of supplies and camping stations are now pretty well established in the great interior country, and the perils of travel are not what they were 10 to 12 years ago. Reports are that shipments of freight to Alaska is much in excess of what it has been in recent years.

KETCHIKAN DISTRICT

(Special Correspondence.)—The Jumbo mine at Sulzer has made three shipments of ore amounting to about 4500 tons since Jan. 1. The large bodies of ore discovered last season while doing diamond-drill work are being opened. About 50 men are employed at present. A small cargo of gold ore was shipped from the Gold Stream mine last month to the Tacoma smelter. The Victory tunnel at Seal Bay is now in over 1700 ft., 10 well defined veins having been opened by it. The main, or War Eagle lode, will probably be cut within the next 300 ft. The Victory company has taken a bond on the adjoining property, known as the Sanford Lhote group, the price named in the bond being $35,000. Some development work has been done on the Veta this winter by Ickis & Polson. The Tongas shaft, Thorn Bay, is now down about 150 ft. The ore is pyrrhotite and chalcopyrite, and contains silver and copper, with some gold.

Ketchikan, March 4.

ARIZONA

GILA COUNTY

(Telegraphic Correspondence.)—One section of Miami concentrating mill was started March 15. Machinery is running smoothly this morning.

Globe, March 16.

(Special Correspondence.)—The Old Dominion company is developing a body of oxidized ore in block No. 2, opened by the west cross-cut on the sixteenth level; this ore assays 10% copper. Development in the United Globe ground is revealing bodies of ore of concentrating grade, both on the twelfth and fourteenth levels. The Old Dominion continues to handle United Globe ores through shaft A. An electrically operated blower is being installed on the twelfth level of the United Globe to keep up ventilation on the fourteenth level until connection can be made with the Kingdon shaft. This shaft is being sunk on the Lady Elgin claim, in the southeastern portion of the property, and is now nearly 70 ft. deep. The Old Dominion is pumping about 3,500,000 gal. of water daily. The hoist installed last August at shaft A has proved satisfactory in every respect. An electric hoist soon will be in place at the Kingdon shaft. When finished it will be the third electric hoisting engine to be installed by this company, which is now operating the Gray and Buckeye shafts by electric power. The electric power supplied by the low-pressure electric turbine installed last July has

resulted in a large conservation of power. Mr. Dowell, the manager, will not give an estimate of the actual saving until he has made further calculations. The turbine is driven by the exhaust-steam from the three compressors, furnishing mine power and ventilation, three blowers that supply the furnaces, and two that furnish the blast for the converters.

The Summit Copper Co. has extended the south drift on the 400-ft. level of the Pasquale vein a distance of 216 ft. from the cross-cut connecting the shaft with the vein. The high-grade chalcopyrite that was found at 142 ft. from the cross-cut is 4 ft. wide at the breast. The north drift heading on the same level is now 160 ft. from the cross-cut and is still in low-grade ore. In this drift high-grade ore was opened 75 ft. from the cross-cut, and was cut by the drift for a distance of 45 feet. A raise will be started at once to explore this body. The raise being driven on the vein from the 400-ft. level toward the 300-ft. is now 70 ft. from the floor of the drift, and the 4-ft. vein containing 2 ft. of ore running 30% copper, and 2 ft. sampling 18%, is still in evidence. On the 200-ft. level both the north and south drifts are in good milling ore.

Miami, Arizona.

Globe, March 11.

PINAL COUNTY

The Ray Con. Copper Co., the mines of which are at Ray, has developed ore deposits of a maximum length of nearly 8000 ft., and of a maximum width of 3500 ft. Ore shipments to the mill, at Hayden on the Gila, amount to 700 to 1000 tons per day, a considerable part of it being mined incidentally to development work. Stoping has been commenced, however. While there is a new working shaft, there are four other shafts which have been used for development purposes. The main haulage adit, by which all the shafts and working levels are connected, has a length of 4000 ft. It is 8 by 14 ft., and double-tracked, the ore-cars being drawn by 10-ton electric locomotives. One section of the mill is doubtless in operation by now.

CALIFORNIA

AMADOR COUNTY

The 80-stamp mill of the South Eureka is operating at full capacity, and although some heavy expenses have been incurred in putting the mine shaft in better condition, the directors have announced an increase in the regular dividend to be paid. The Hardenburg mine is being equipped with a new air-compressor.

BUTTE COUNTY

The Burlington Gold M. Co., of which W. C. Ralston, G. W. Grayson, H. T. Creswell, E. B. Braden, and W. S. Graham are directors, has the New Burlington, Mexican, Jo and Annette claims, situated near Forbestown, these locations covering 4498 ft. of the New Burlington lode. This lode has a north-south strike, a dip of 55 to 65° northeast, stands between diabase and greenstone, and has a width varying from 2½ to 25 ft. On the Burlington claim are 10 test-holes along the cropping; the Mexican has a 100-ft. adit, which is caved; on the Jo is a 335-ft. adit, and some cross-cuts, and there is a small amount of development work on the Annette. Engineers who have examined the property have concluded that this lode and that in the Golden Queen are the same, though the latter has been displaced by faulting. It has been recommended that two 500-ft. shafts be sunk on the group. Samples of ore have assayed $4.75 to $160 per ton in gold, with some silver. It is estimated that with a mill having the capacity of 300 to 500 tons per day the ore may be mined and milled at a cost of $2 per ton. The company is now active and it is reported that a mill is to be built this year.

CALAVERAS COUNTY

The Water Lily mine, situated near Melones, on the Stanislaus river, has a force of 15 miners, who are taking out 50 mine-cars per day of auriferous gravel, said to yield $3 per car. John Whitney has charge of the work.

ELDORADO COUNTY

The Mother Lode Mines Co., operating the Kelsey mine, situated near Placerville, is so encouraged by results of development that it contemplates erecting a mill on the property next summer. W. A. Hooten is engineer in charge.

KERN COUNTY

The Phoenix mine and 5-stamp mill, near Randsburg, are active again. The mine has been considerably developed, and in a new shaft being sunk a 3-ft. vein of ore was opened, the gold in which amounts to $10 to $20 per ton. C. A. Burcham owns the property. The Arondo mine and mill, situated in Argus mountains, out from Randsburg, are being operated with a force of about 30 men. J. K. Miller is in charge.

MONO COUNTY

The power plant and other buildings of the California Hydro-Electric Co., situated at Jordan, were wrecked by a snowslide on March 8, and, according to reports, 8 or 10 persons were killed. Among the killed are John Sullivan, Ben Pessin, Harold Hardy, F. Stromboli, R. H. Mason, Harry Weir, and P. M. Peacock. Transmission lines of this company extend to Hawthorne, Rawhide, Fairview, and Wonder, Nevada, but it is understood they connect with another system whereby light and power can be supplied to those places.

NEVADA COUNTY

The Pittsburg mill now has 20 stamps in operation, the installation of 10 additional stamps having been completed recently. The property is at Nevada City, and is owned by the Pittsburg Gold Flat Mines Co., Mark B. Kerr being manager.

PLUMAS COUNTY

The Crescent Hill mine and mill, purchased some time ago by W. E. Oddie, are being operated successfully. J. Tefft, who sold the Crescent Hill, is developing a mine on an adjoining property. The properties are situated six miles south of Quincy, near the middle fork of Feather river.

SAN BERNARDINO COUNTY

Hart district is equidistant from Searchlight and Barnwell, and contains some gold-bearing veins of ore which have been developed considerably during the last three years. The Oro Belle, in charge of W. B. Andrews, may be provided with a 10-stamp mill, and it is claimed a sufficient tonnage of ore is available to warrant it. Sinking is in progress to obtain a supply of water, which is almost as important a factor as the ore-supply. The Jumbo, in the same district, first developed to some extent by the Quartette company of Searchlight, is now in control of the Big Chief company, by which further development is to be done. Other properties of the camp include the Flyer, and Rambler.

SHASTA COUNTY

(Special Correspondence.)—It is reported that the Milkmaid will be equipped with a cyanide plant in the spring. Developments are progressing at the property, and some good ore is reported. It is understood that the Black Tom company is planning to resume work at the Niagara group within a short time. Mr. Riordan, managing director of the Bully Hill Copper Co., is looking over his company's holdings. It is rumored that the company is planning the resumption of activities at its mines, but nothing of an official nature has been given out. The smelter has been idle since last July, owing to the complaint of the Forest Service, which claimed that the fumes were seriously damaging Government timber. At the Gladstone, rich ore continues to be mined below the 500-ft. level. A full force of men is employed, and the mill is operating at full capacity. The monthly clean-up averages $30,000 to $45,000. I. O. Jillson is managing director, and E. Young superintendent. Developments are progressing at the Mad Ox. It is reported that H. O. Bals, formerly in charge of the mine, will again direct the affairs of the company. The Midas is maintaining its usual heavy production. At the Gambrinos, five stamps are in action. The past winter has been unusually moderate in this county, consequently the mines have been able to maintain constant operations without difficulty.

Redding, March 11.

SIERRA COUNTY

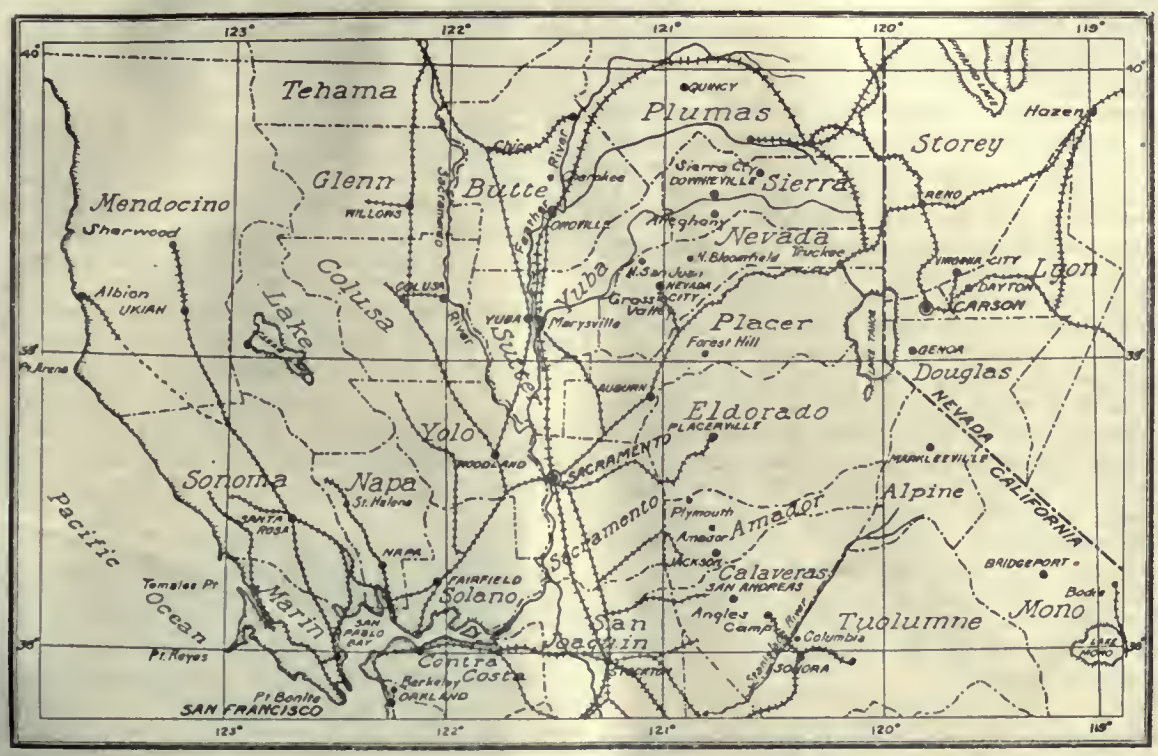
The Sacred Mound mine, under bond and lease to George A. Aldridge and associates, has good ore in a vein recently found. A tramway has been built to carry ore from this vein to the Butte Saddle mill.

TUOLUMNE COUNTY

(Special Correspondence.)—The Street mine, at Tuttletown, owned by Richard Kinsman, of Oakland, but recently bonded to Barret and Snoogoose, is being re-opened for extensive development. The shaft will be sunk several hundred feet deeper. There is a 5-stamp mill on the property. The new mill at the Berkeley is approaching completion. Within a few days a new pump will have been installed and the mine unwatered, when a crew of miners will be put at work. A small stamp-mill probably will be purchased soon for the Gianelli mine, situated near Arastraville, and owned by James J. Masgheno. Development has proved the rich shoot of ore uncovered several weeks ago to be of fair size. Preparations for beginning gravel mining on the Mill Villa are being made. The property is between Sonora and Jamestown, and has just been deeded to John W. Cobb by the San Francisco Power Co. A shipment of three carloads of ore is being made weekly from the Black Oak mine to the Selby Smelting & Lead Co. Operations have been discontinued at the Donella mine, above Arastraville, formerly worked under a bond held by George H. Brown. The mill at the Mazeppa has been started. It is reported that operations will soon be resumed at the Omega. The new mill at the Duffield, near Arastraville, will soon be ready for operation. When started a larger force will be employed in the mine.

Tuolumne, March 11.

The Badger group of mining claims, situated four miles from Jamestown, has been purchased by A. L. Ellis, who intends to have considerable development work done this season. The property, which has been idle a number of years, was formerly a producer. One of the requisites to operating will be to unwater the old workings.



Central California.

COLORADO

CHAFFEE COUNTY

The Monarch-Madonna mine, situated 20 miles west of Salida, which was a rich producer of ore from 1882 to 1894, was practically idle for 14 years following the last date; but about a year ago the property was purchased by Burton brothers of Leadville. The great vein had been opened and the ore taken out through a series of adits, five in all. Burton brothers had the sixth adit driven, lower than any of the others, and at a distance of 1500 ft. from the portal they opened the vein, finding it as wide at this depth as above, and the ore of even higher grade. In fact, whereas lead and zinc predominated in the higher workings, it was found that silver and gold prevailed in the ore opened on this lowest level. During the last nine months of 1910 they shipped ore of the net value of $105,000; this ore was taken from the stopes between the sixth and fifth levels.

CLEAR CREEK COUNTY

(Special Correspondence.)—It is said that a net earning of $8000 per month is being made by the Pay Back M. Co., operating the Josephine mine on Kelso mountain. From 10 to 12 tons of $60 ore are being sold daily. The output from the Capital mine during the month of Feb-

ruary was a little over $30,000, and it is believed that March will witness that amount being doubled. The Pioneer mine, on Covode mountain, has been taken under bond and lease by J. H. F. Smokey, representing Cripple Creek mining men. Development work is to be commenced at once. This property has been a steady producer of smelting and concentrating ore for several years. A body of ore from 16 to 20 in. wide has been opened in the breast of the adit on the Mint vein, samples of which assay $45 to the ton in gold. The operating company will start the 10-stamp mill before the end of this month. The Bard Creek M. Co., operating a group of claims on Lincoln mountain, is making ready to perform development work. As soon as the roads are in good condition shipments of smelting ore will be started. The Homestake G. M. Co. has given another contract to E. C. Bovie to drive the adit 100 ft. This will take the heading past the Homestake vein.

Georgetown, March 5.

(Special Correspondence.)—The Lucania adit, at the mouth of Fall river, is to be driven 1500 ft. L. Sternberger, owning a vast mining estate on Bellevue mountain, has agreed to perform the work to compensate for a right-of-way in the adit. Ground will be broken at the rate of not less than 7 ft. each day. Development is to be carried forward at the Gum Tree mine at Freeland. Shipments of ore to the Golden smelter have commenced. Owen & Co., who recently secured a lease on the Bellman vein, and who are operating through the Central adit, have work well advanced. Shipping ore has been found, and within a short time a heavy tonnage will be marketed. The discovery recently made on the Good Friday mine, situated on Red Elephant mountain, is improving with the shooting of each round of holes. The orebody is 12 in. wide, and from shipments that have been made returns of 150 oz. silver per ton have been realized. R. B. Morton is manager. Occasional shipments are going out from the White property, the ore milling from 225 to 250 oz. silver per ton. Operations are in progress through the Commodore adit. A streak of ore 10-in. wide has been uncovered on the Ten Spot property on Santa Fé mountain that is worth $18 per ton in gold.

Idaho Springs, March 4.

GILPIN COUNTY

(Special Correspondence.)—Work is to be resumed on the O. K. mine, situated on Central hill. The shaft that is down 620 ft. is to be sunk 100 ft. deeper. Eilman Bros., leasing on the 620-ft. level, are making regular shipments of concentrating ore. Shipments of mill dirt have been started from the Newfoundland mine. Work is being done on the twelfth and thirteenth levels. A. H. Rose is manager. A local pool of operators is developing the Alger-Kansas mine. Stoping has been started on an 18-inch streak of ore that mills 2 oz. gold to the ton. A. C. Most has secured a bond and lease on the Comet mine, and the work of exploration has been started. A streak of ore 18 in. wide has been exposed that shows assay-values of from $12 to $30 per ton. Ore is to be shipped from Coeur d'Alene mine, situated on Academy hill. Operations are in progress on the 700-ft. level, a big body of smelting ore being exposed. Recent shipments have brought returns of $60 per ton. The shaft on the Paola is to be sunk 100 ft. A streak of ore 8 in. wide is exposed in the deepest workings that is worth $30 per ton. After years of idleness, work has been resumed on the Central City mine. R. R. Demeter is owner.

Central City, March 6.

LAKE COUNTY (LEADVILLE)

The Crysolite mine, an old property on Fryer hill, has passed to Howard E. Burton and associates under a ten-year lease. The intention of the lessees is to employ a force of miners and prospect the ground for carbonate of zinc. The same lessees are operating the Seneca, Little Chief, and Little Pittsburg. Zinc carbonate is being mined in that part of the Seneca opened from the Hayden shaft. The Western M. Co. has a good force of miners at work at the Wolftone shaft, Castle View, and Big Chief, on Carbonate hill. The Evelyn is also being operated by M. A. Nicholson and associates. The mines in this locality are producing about 800 tons per day of zinc carbonate. The output of zinc carbonate by Leadville mines during 1910 amounted to 20,680 tons. A large increase over these figures is anticipated for 1911.

OURAY COUNTY

The San Pedro M. Co., owning a large area of patented ground adjoining that of the Camp Bird, is controlled by New York men, whose plans are said to contemplate the building of a mill. Development work has resulted in opening five veins, in which is blocked out about 300,000 tons of ore. A development and building fund of $150,000 is being raised by the stockholders. The Atlas mine, near Sneffels, has a mineral lode which is exposed for 5000 ft. on its strike, and has been opened to a depth of 1200 ft., by which a great tonnage of milling ore is made available. The Atlas company now has a 10-stamp mill, and has in view the building of a much larger plant.

SAN JUAN COUNTY

The Sunnyside mine, belonging to the Terry estate, and being operated by Terry brothers and their sister, Mrs. Strong, is said to be under option to a syndicate of Eastern men, whose engineers have reported 441,000 tons of ore in sight, capable of yielding a net profit of $2.35 per ton. The general direction of the mine and mill work is in the hands of Walter Bunce. The mill is at Eureka, the mine being over a mile distant from there, near the head of Eureka gulch.

IDAHO

IDAHO COUNTY

The Elk City Reduction Co. is erecting a custom mill at Elk City. The plant provides for plate-amalgamation, concentration and cyanidation, and will have a capacity of 20 tons per day.

LEMHI COUNTY

The Pittsburg-Idaho company, which operates the old Gilmore mine in Lemhi county, Idaho, has been shipping from 100 to 125 tons per day to the Salt Lake smelters. New machinery has been purchased and the output will be increased. According to A. S. Ross, a dividend was to be paid on March 15, which will probably be increased at a later date.

SHOSHONE COUNTY

(Special Correspondence.)—Ore of good grade has been uncovered in the new tunnel being driven on the Ajax property in the Coeur d'Alene district. The owners are negotiating for the use of one of the Moonlight company's tunnels, which, with 500 ft. of extension, will permit the development of the orebody at depth. The vein was uncovered 200 ft. in from the portal of a drift below the old workings. A drift to the east, now in 100 ft., has been in ore the entire distance on the hanging wall. The face shows 18 in. of quartz, carrying 20% lead.

Wallace, March 11.

(Special Correspondence.)—Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 172, of $81,750, on March 4, making a total of $12,538,350 to date.

Kellogg, March 8.

Shipments of ore from the Jack Waite mine were commenced about March 1. The mine is 12 miles from Eagle station, near Murray, and the ore is sacked and hauled on sleds to the railroad. A recent shipment of 500 sacks is said to have sampled $70 per ton in lead, silver, and gold. It is possible that a spur of the Idaho Northern railroad will be extended to the mine, as P. Burke, the manager, undertakes to guarantee the shipment of 100 tons of ore per day from this mine.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Five of the eight directors of the Barnes-King company elected at the annual meeting recently held at Kendall, are Butte men. The New

York people were headed by W. H. A. Fischer. The five Butte men selected are C. W. Goodale, manager of the Great Falls smelter; Andrew J. Davis, president of the First National bank; W. C. Lewis, a business man, John E. Corette, and John K. Kirk, attorneys. The Eastern men were given three directors. It is expected that the future of the Barnes-King mine will be decided March 30, when an adjourned meeting of the new directors will be held to consider the question of investing the cash in the treasury, or at least a part of it, in some other property, or dividing it up and winding up the affairs of the company. The new directors have elected C. W. Goodale president; E. G. Hothorn, of New York, vice-president; C. C. Swinborne, treasurer; John E. Corette, secretary, and Jas. A. Bailey, assistant secretary-treasurer. Mr. Bailey and Mr. Hothorn are residents of New York. In addition to the local directors, W. H. A. Fischer, of New York, the retiring president, was present. There were forty properties considered, and the conclusion was reached that of these there were three which might prove a profitable investment, so it was decided to have them examined. This conclusion was reached after having discussed the advisability of winding up the affairs of the company and dividing the money in the treasury among the stockholders *pro rata*.

Lewistown, March 11.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—Developments on the 300-ft. level of the Auto mine, at National, have resulted in opening a 10-ft. vein, the ore in which is said to be of good milling grade. The National Mines Co. is developing at several points and opening much rich ore. The mill is operating on high-grade quartz. The company has paid

National, Nevada.

a total of $345,000 in dividends since the discovery of ore about two years ago. It now ranks as one of the best properties in the State. The ore recently found on the A and T claims, on the north side of Winnemucca mountain, is gaining importance with developments. The vein has a width of from 14 to 18 ft., the ore containing 2 oz. of gold to 1 oz. of silver. The Nineteen-Ten Mining Co., at Barret Springs, is now an ore shipper. Seven tons of ore are being sent out daily from the Cole-Bullis lease, recently acquired by the parent company. The vein is 3 ft. wide, and all the ore is reported to be of shipping grade. J. M. Blood is superintendent. A 2-ft. vein of good ore has been opened on the Blue Bell, and a few cars will soon be sent to the smelters.

Winnemucca, March 8.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The clean-up made at the Socorro mines for the last half of February amounted to 19,500 oz. of gold and silver bullion. The Wilfley tables were re-installed in the mill, and they are turning out 3½ tons of high-grade concentrate per week. The driving on the 500-ft. level is soon expected to tap the vein; and the Queen vein was opened on the 700-ft. level by driving a cross-cut from the shaft, exposing 7 ft. of ore, having an average assay-value of $12 per ton. The clean-up of the Ernestine M. Co., as the result of 14 days run, amounted to 8475 oz. of gold and silver; and for the last week of February 686 tons of ore was treated, the concentrates amounting to 45 sacks. The manager for the Mogollon Gold & Copper Co. has returned to camp, and it is reported that the force of miners will be increased. It is reported that the Treasure Mining & Reduction Co. is considering the establishment of an aerial tramway from the mine to the mill. At present the ore haulage is by wagons. It is reported that the Maud S. mine has been acquired by a New York syndicate, which will re-open the mine and mill. The mill and other surface improvements are in good condition.

Mogollon, March 10.

OREGON

BAKER COUNTY

The Golconda mine, situated in Cracker district, four miles from Sumpter, is to be re-opened by William Kinnear, of Susanville, who has taken possession under a bond and lease. A syndicate of Spokane men is said to be backing Kinnear. The Golconda, which has been idle about six years, formerly produced high-grade and is understood to have now an abundance of low-grade ore. The property is equipped with a 20-stamp mill for amalgamating and concentrating.

UTAH

It is announced in Salt Lake by E. P. Mathewson, general manager for the International Smelting & Refining Co., that lead furnaces are to be installed in the plant of this company at Tooele, and that designs for them are being made. Much interest attaches to this announcement, as it presages additional competition in the smelting of ores other than copper in the inter-mountain country. The silver-lead districts, outside of the Coeur d'Alene, which may be drawn upon for ores suitable for the lead-smelter are Park city, certain parts of Bingham, Stockton, Tintic, Beaver county, American Fork, Utah; Wood river, and Lemhi county, Idaho; and such camps in Nevada as Pioche, Hamilton, Ward, and Eureka. The entrance of this company into the lead-smelting industry will open the fourth plant for custom ores in Salt Lake valley, the three now in operation being that of the U. S. S. R. & M. Co. at Midvale, and those of the A. S. & R. Co. at Murray and Garfield.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—A pay-streak has been found on the Rico placer ground, on Gold creek, 20 miles south of Republic, where a bedrock drain 450 ft. in length has been cut. The drain is 16 ft. deep at the head, and overlying the bedrock the pay dirt is 3 ft. deep, and yields from 50 to 75c. per cubic yard. The gold washed is shot, flake, and dust. Gold creek has a fall of 50 to 60 ft. to the mile. The present find is the result of eight months prospecting.

In raising from the 100-ft. level of the Quilp mine a deposit of quartz, rich in argentite and native silver in crystals, has been opened. The north drift on the vein on the 400-ft. level of the Quilp has passed from the Quilp 44 ft. into the Surprise ground. The drift is about 7 ft. wide, and samples from the face assay from $37 to $43 per ton. The cross-cut from the main incline shaft on the Surprise ground has broken into a body of shipping ore, on which a drift has been started, and a raise will be made to the winze below the Jim Clark adit, where some rich ore has been developed. A winze is being sunk below the 300-ft. level of the Lone Pine mine on a body of ore from 6 to 10 ft. wide and about 56 ft. long. The assays show from $15 to $100 per ton. The San Poil Consolidated company has taken over the San Poil, North San Poil, Snowstorm Fraction, one-half of the Kangaroo, and the Trade Dollar claims. Five men are employed on the 300-ft. level of the San Poil. In the south drift, 435 ft. from the main adit, two men are raising on a deposit of ore

from 6 to 10 ft. wide, which assays about $21 per ton, of which $16 is in gold. The drift on the vein to the northward is in about 430 ft. and has penetrated the North San Poil ground, on which a raise toward the North San Poil shaft is up about 60 ft. on a solid shoot of ore, 7 to 8 ft. in width, which assays about $35 per ton, in relative proportions of 4 oz. silver to 1 oz. gold. J. W. Turner, of Spokane, is the general manager for the company. In the Knob Hill mine 27 men are employed, of whom 10 are on machine-drills. Development is progressing on the No. 2 and 4 levels. On the No. 2 a drift is being driven on a lateral vein, and assays of 24 samples averaged $49 per ton. This vein makes a sharp bend to the west and is being followed to a supposed junction with a parallel vein. On the No. 4 level a cross-cut is being driven, with 40 ft. further to run and get under a shoot of ore on the No. 2 adit-level, 172 ft. above. On the No. 1 level are about two carloads of ore sacked and ready to be shipped.

Republic, March 11.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—The operations of the Consolidated company at its Trail smelter during the month of January resulted in a metallic production valued at $349,000, of which over 58% was gold. Over 34,500 tons of ore was received at the smelter, of which 32,958 tons was treated. During the seven months ended January 31, this company has produced metals valued at $2,645,000. A shipment of $50,000 worth of silver 0.999 pure was recently sent from the Trail refinery to Hongkong, where it will be used for coinage purposes. The January report of the Le Roi No. 2, Ltd., shows that 2010 tons of ore and 91 tons of concentrate were shipped to Trail smelter. The smelter receipts amounted to $32,308. The estimated costs for the same period were: Development, $8500; ore production, $9500; milling, $1500; a total of $19,500. The new Holywell vein in the Josie mine is proving up well. A recent assay from the East drift showed 9 dwt. gold 5½% copper, while an assay from the west drift showed 11 dwt. gold and 3⅜% copper. A two-shilling dividend was paid early this month. The Le Roi No. 2 owns a controlling interest in the valuable Van Roi mine near Silverton.

Rossland, March 10.

(Special Correspondence.)—Shipments of ore from the Granby mines were lower during the last two weeks, owing to break-down of the electric hoist at the Victoria. This has now been repaired, and the full battery of furnaces at the Grand Forks smelter is blown in again, and shipments are now about normal. In about two months ore will be available through the No. 3 adit which the Granby company is driving at the Phoenix mines. The Consolidated company, of Trail, is planning to build a cyanide mill to treat ore at Boundary Falls from the No. 7 mine. A crusher is being installed to break the ore at the Rawhide mine. The earnings of the British Columbia Copper Co. for January amounted to $17,034. The cost of producing copper was 11.59c. Smelter trouble increased the cost slightly above normal figure. The January production was 827,272 lb. copper, 2376 oz. gold, and 9545 oz. silver. The operating disbursements of the company for the fiscal year ended November 30, 1910, were $1,158,294; custom ore purchased, $51,894. The copper yield per ton of ore was 18 lb.; gold and silver, $1.23 per ton.

Phoenix, March 11.

MEXICO

SINALOA

The Mexican American S. & R. Co. has just taken a ten-year lease on the Carmen mine. The property is owned by German and American interests. A quiet campaign of development has put 150,000 tons of silicious silver ore in reserve. The Mexican American company expects to ship to its smelter at Guaymas at the rate of 100 tons per day. The smelter will probably be put in blast within three months.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. C. Hoover is at New York.

F. J. Estep was in San Francisco.

H. C. Nutter was in San Francisco.

S. H. Brockunier is in San Francisco.

W. S. Noyes will leave for Texas today.

Lewis T. Wright will be in Mexico next week.

A. B. Colwell, of Ely, was at Mason, Nevada, lately.

Courtenay DeKalb was in San Francisco this week.

S. F. Hunt, of Hamilton, Nevada, has gone to Alaska.

Howard D. Smith has gone to Los Angeles and Mexico.

Charles Helman, of Oroville, has been in San Francisco.

Duncan MacVichie was at the Palace hotel in San Francisco.

J. A. Holmes addressed the Southern Commercial Congress at Atlanta, Georgia.

Henry Krumb, consulting engineer for the Inspiration Copper Co., is at New York.

F. H. Bostwick, western manager for the Wellman-Seaver-Morgan Co., is at the Palace hotel, San Francisco.

D. E. Blake, who recently returned from the Philippines, has gone to the Yaco mines near Rosario, Sinaloa, Mexico.

Walter Douglas, general superintendent of the Copper Queen mines, Bisbee, Arizona, is at the Palace hotel, San Francisco.

J. B. Keating, manager for the Bully Hill Copper Mining & Smelting Co., operating in Shasta county, California, was at the property recently.

George F. Waddell, superintendent at the concentrator of the Steptoe Valley M. & S. Co., has been at Butte and Anaconda, Montana, for the week.

L. W. Armstrong has resigned as superintendent for the New England & Clifton Copper Co., at Clifton, and is now with the Ray Con. at Hayden, Arizona.

Sumner S. Smith, in charge of a U. S. Bureau of Mines rescue car, has been at Carson and Reno, Nevada, and will go to Ely before returning to Wyoming.

T. Lane Carter, of Chicago, is examining mines in Jalisco and Tepic, Mexico. His address for the next month will be, Zapopan mine, La Yesca, Tepic, Mexico.

The Utah Society of Engineers held its monthly meeting March 17 at Salt Lake. The paper for the evening was by A. S. Peters, on 'Protection at High-Tension Line Crossings.'

Herbert C. Enos has returned to Mexico City from Chihuahua, where he has been temporarily in charge of the Buena Tierra mine owned by the Exploration Company of London.

Francis K. Sewell, recently at Zacatecas, is now at Villa Escobedo, Chihuahua, where he has charge of the Kelley filter-presses in the new mill of the Veta Colorado M. & S. Company.

F. Curtis, who has been in charge of sampling and experimental work for the Steptoe Valley M. & S. Co., has resigned to enter the employ of the Miami Copper Co., Globe, Arizona.

L. Vogelstein & Co. give the following figures of German consumption of foreign copper in January 1911:

	Tons.
Imports of copper	13,329
Exports of copper	639
Consumption of copper	12,690

The consumption in January 1910 was 14,750 tons. Of the quantity taken in 1911, 11,714 tons was imported from the United States.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

LIABILITY FOR DEATH OF PERSON RESCUING IMPERILED MINERS

A complaint for damages for the death of a rescuer who perished in a mine, alleged that a fire had been burning for some days in a coal mine, and during such time one of the ventilating fans had been stopped for one day and by reason thereof gases accumulated in the mine through which men going in to subdue the fire must pass; that on the next day the fan was started in the mine, but had not been running a sufficient time to clear the passageways of the gases; that the corporation operating the mine did not examine to ascertain the condition of the passageways, but the superintendent and general manager for the company sent several miners in to subdue the fire without being informed as to the presence of these gases and being overcome with them were in peril of their lives; that at the request of the superintendent, the deceased, without knowledge of the prevailing conditions, entered the mine to aid in the rescue; that the defendants wholly disregarding their duty, negligently failed to inform the deceased as to the existence of the poisonous gases that had accumulated in the mine, that were existing from the negligent acts and conduct of the defendants, and negligently failed to advise the rescuer, the deceased, of the gases then existing in the mine, and that the said rescuer, ignorant of such lack of ventilation and suspecting and believing that the only dangers to which he was then exposing himself in the work of rescue, were the dangers and risks which arose from the gases then being created on account of the fire in the mine, and that he entered the mine for the purpose of rescuing the persons therein, and after so entering, and while so performing the work of rescue, was overcome by the gases, in consequence of which he died. The recovery was sought upon the theory that the defendants were chargeable with the death of the rescuer by requesting or permitting him to enter the mine for the purpose of rescuing the imperiled miners without informing him of the dangerous condition known, or which should have been known to them to exist therein, and thus exposing him to a peril of which he had no knowledge. The alleged peril did not exist by reason of the fire, nor of the gases generated by it, but the peril of the miners was due to the accumulation of gases spontaneously generated in the unused workings, and that the accumulation of such gases in the passageways was the cause of the death. It is a rule of law that one who, observing another in peril, voluntarily exposes himself to the same danger in order to protect him or save his life may recover for any injury sustained in effecting the rescue against the person through whose negligence the perilous condition was brought about, provided, however, the rescue is not made under such circumstances as to constitute rashness, in the judgment of prudent persons. The rule rests upon the principle that it is commendable to save life, and though a person attempting to save it voluntarily exposes himself to danger, the law will not readily impute to him responsibility for an injury so received. The incurring of the danger in such cases is not *per se* negligence, and the question of contributory negligence depends upon the proof of the circumstances surrounding the attempt to rescue, such as the alarm, excitement, and confusion usually present, the uncertainty as to the means to be used, and the liability to err in the exercise of judgment as to the best course to pursue, and great latitude of judgment is allowed to one who is impelled by the dictates of humanity to decide and act in the face of emergencies. The court, however, found that the death of the rescuer was caused, as shown by the evidence, from gases generated by the fire, and that inasmuch as the complaint alleged, and the case proceeded on the theory that the rescuer's death was due to the inhalation of gases other than those generated by the fire, and having failed to furnish evidence to establish, directly or indirectly, that the death was caused as alleged, there could be no recovery, as the divergence thus appearing between the cause of action as alleged and the evidence adduced to establish it, is such a variance that it amounts to a failure of proof, and brings the case within the rule that, unless evidence furnishes substantial proof of the cause of action as alleged, the plaintiff has failed to make out his case, even though the case shows negligence in other respects. The rule is that the evidence must tend, not only to show the negligence alleged, but also the causal connection between it and the injury.

Bracey *v.* Northwestern Improvement Co., (Mont.) 109 Pac. 706. June 1910.

AUTOMATIC FUEL-OIL REGULATION

Practically all oil-fired boiler plants are controlled by hand. Steam as well as oil is regulated at each individual burner, and the dampers are also subject to hand-control. Results obtained are hardly ever satisfactory, and the efficiency of the boiler plant is correspondingly low. The first notable step in advance of hand firing was at the plant of the Pacific Electric Railway Co., Los Angeles, Cal., where under the direction of the chief engineer, one man stationed near the oil pumps, running at practically constant speed, controlled 18 boilers or 54 burners by opening or closing a bleeder valve on the oil-pump discharge-line, thereby increasing or decreasing the pressure in the oil main and simultaneously the rate of firing of all the boilers. After this it was a simple matter to substitute automatic regulation for hand-control, thereby developing the Moore patent automatic fuel-oil regulating system. This system controls the supply of oil to all burners, the supply of the atomizing agent to all burners, and the supply of air for combustion, for any number of boilers, all from a central point. The results include, increased boiler plant efficiency, the practical prevention of smoke, and the decrease in the maintenance cost of boiler equipment; all due to a more uniform manner of firing.

Under actual operating conditions this system of regulation has been found absolutely reliable. In 1909, or about two years after this apparatus was installed, A. C. Balch, general manager of the Pacific Light & Power Co., expressed his opinion in the following letter to the designers:

"Referring to your inquiry, we are pleased to advise you regarding results with your automatic regulating system. As you know, we have in our plant at Redondo, 18 Babcock & Wilson boilers, each rated at 604 hp., with three burners per boiler, or 54 burners in all. The entire boiler plant has now been equipped with the Moore automatic fuel-oil regulators for the past year, which control the steam pressure, the fuel-oil pressure, the supply of steam to burners for atomizing the oil, and the operation of boiler dampers for the purpose of regulating the supply of air for combustion. With this system we maintain practically a uniform pressure while in operation. One-third of the plant has been under automatic control for a period of over 18 months. The remainder, as stated above, was equipped with your regulators one year ago and the entire plant is now operating under this condition. During this time we have never suffered an interruption of service, or loss of steam pressure, due to failure of regulators to operate; they are simple in design and positive in action and we find them capable of ready adjustment by the operative firemen. Our plant is subject to widely swinging railway load and we find under all conditions the boilers respond to these fluctuations of load almost instantly. As the result of installing this equipment, we find the load is more equally divided among all of the boilers in service than under hand firing, and the boilers are free from abuses due to excessive rate of firing periodically experienced with hand regulation on variable load. It is usually the case, in attempting to hand regulate fires on reduced air supply, that the chimneys will smoke frequently on variation in loads; as a result of the automatic system of regulation the smoke nuisance has been reduced to a minimum. We consider the regulating system thoroughly practical, reliable, economical in operation and a demonstrated success."

At this time, 1911, after this system has been in operation a number of years, the Southern California Edison Co. is putting in a similar equipment. This in itself is conclusive proof that the Moore patent oil regulating system tends to make the operating conditions ideal, particularly in the plants where the load is variable and difficult to handle by hand regulating on account of frequent adjustments. A bulletin of 'Unnecessary Losses in Firing Fuel Oil and an Automatic System for Eliminating Them' can be obtained at any of the offices of Chas. C. Moore & Co., San Francisco, Los Angeles, Seattle, Portland, and Salt Lake.

EDITORIAL

BUCKHORN is the name given to the new mining camp on Fort Sage mountain north of Reno. An old-time rush to the district is in progress, and in Nevada, at least, there is a general feeling that the State has again 'come back.'

PERUVIANS are planning to invite the American Institute of Mining Engineers to hold a session in their country. It would be a much appreciated compliment even if the officers of the Institute should find it impossible to arrange such a meeting.

ANGLO-AMERICAN friendship will be exemplified next week when an American woman will christen a British battleship, H. M. S. *Monarch*. Kinship does not always have friendship as a correlative, and international amenities can never be too frequent.

TELLURIDE ores are usually associated mentally with Cripple Creek and Western Australia, but in reality are of widespread occurrence. When present they have a marked influence on metallurgical processes, and in the abstract of the paper by Mr. Sharwood, which we present this week, these features are discussed.

APPROPRIATIONS for the work of the United States Bureau of Mines for the present year are the same as for last, and amount to $475,500. There is a possibility of $35,000 additional becoming available for testing coal. An increase of this amount was made in the Senate and, though disallowed by the conference committee, appears in the bill as printed.

AN ADVISORY committee on mineral statistics has been appointed by the American Mining Congress to promote co-operation between mineral producers and the Government and State bureaus engaged in collecting statistics. There is need for greater uniformity and for simplification of schedules. If the simple reform of requiring reports for periods ending at the same date could be brought about, much unnecessary work would be avoided.

NICARAGUAN conditions are becoming stable. The United States Government is now a powerful factor in the administration of that country, acting through an advisory committee. It is reported that New York bankers are to loan $12,000,000 to Nicaragua. In the meantime mining activities are reviving. Several properties have been bonded or leased and mining men in the United States are turning their attention to our southern neighbor.

PLATINUM has risen to double the value of gold, and search for new occurrences of platinum and platinum ores will be correspondingly stimulated. A rich concentrate is now being made at the Rambler mine in Wyoming, but the production in this country is still unimportant.

PRODUCTION at the Braden copper mine in Chile is expected to begin in April. Large ore reserves have been opened, a railway built, and a smelter erected; all to make available rock containing but 2.7 per cent copper. This gives some suggestion of the demand for that metal incident to modern industrial progress.

LABOR TROUBLES have taken a peculiar turn at Gillespie, Illinois, where rioting has threatened at the mines of the Superior Coal Company. The new manager, Mr. John P. Reese, undertook some reforms, introducing mining machines and attempting to break up a vicious surreptitious practice whereby the more ignorant of the foreign laborers had paid petty bosses for jobs or favored places in the mines. A large number of men were discharged, and the others promptly struck. Mr. Reese, who was at one time a prominent labor leader in Iowa, promptly laid the matter before the Union officials who as promptly sustained him and ordered the men back to work. A number refused to obey and attempted to intimidate the others, whereupon the Governor, Mr. C. S. Deneen, rushed troops to the scene, and the ensuing quietness was almost resonant. It would be better if troops were oftener sent at the first threat of trouble, instead of waiting until damage had been done.

THE OLD-TIME PROSPECTOR, it is said, never had time to make a mine. If he opened a good body of ore he seldom lingered beyond the time necessary to make a few assays. This trait of the prospector is, apparently, common to all humanity. The porphyry coppers have been the cause of more discussion than anything in copper mining for many years. The Ray Consolidated is just at the point of initial production, yet the price of its stock has declined to where it is probably proportionately cheaper than it ever has been. The precious metal camps fare no better. Tonopah has been making splendid records and developing big mines, yet there is more public interest in some of the Nevada camps where there are no mines, than there is in Tonopah. A still more striking illustration is a comparison between Cobalt and Porcupine. The former is sending out more real money to its shareholders in the form of big dividends than it ever has since the day of its discovery. The life of the camp has by no means been finally determined. Yet Porcupine, with its uncertainties and its unknown possibilities, and which is for the most part undeveloped, is more alluring to the public than Cobalt with its dividends. The public, like the prospector, is not particularly anxious to make mines, nor to receive regular dividend checks, but likes the zest of playing the game with nature.

Phosphate Claims

Whether lands containing phosphate rock should be entered as placer or lode claims has recently been much discussed in the technical press. Unfortunately, a number of the writers have gone wrong as to their facts. The best general statement of the case has been made by Mr. Carpel L. Breger, in *The Mining World*. His paper is too long to review, but we wish to express essential agreement with his conclusions. Phosphate rock, unfortunately, was not known to occur on public lands when the mining laws were enacted. As it differs essentially in mode of occurrence from the minerals that the law was framed to cover, no really adequate provision exists for the entry of phosphate land. As a result, entrymen have been put to much unnecessary expense both in doing double assessment work and in litigation, while there is even yet no certainty as to the correct form of entry. As a matter of fact the Western phosphate deposits occur in beds and are neither veins nor placers. Unfortunately this statement of fact does not solve the legal questions at issue. The first locations, both in Florida and in the West, were made under the placer law and patents were so issued. Instead of following up this advantage the early locators, feeling then sure as to results, held their ground by doing assessment work and were slow to proceed to patent. When Bradley Brothers bought placer locations in the West, they, with possibly an eye to the extremely valuable extralateral right involved, re-located the ground under the terms of the lode law and obtained patents. The Land Office has therefore given title under both lode and placer laws. In extenuation, it may be said that in neither case was there a real contest and also that the officials have stated that the giving of a lode patent is not to constitute a precedent. Apparently the officials of the Department have attempted to decide each case on its merits. The difficulties in such a course of procedure are evident. In one instance there is a lode patent on the outcrop of a given bed on one side of a syncline, and a placer location on the same bed on the opposite side. In many cases both lode and placer locations cover the same ground and are in different hands. A small group of speculators at Salt Lake has 97 lode locations, many of them overlying older placer claims. If these lode re-locations are allowed to patent, a practical monopoly of the phosphate land not yet withdrawn from entry will be created. That, of course, has no bearing on the legal question involved, but is of interest to laymen, since the impression has been created that the great corporations are attempting to 'grab' the phosphate land at small expense under the terms of the placer law. At the last session of Congress the House passed an act providing that in deciding the various contests, either lode or placer locations should be considered valid, and, in effect, that the contest should be determined on the basis of priority and good faith. It was defeated in the Senate, but may well come up again in the special session. The attempt to create prejudice against it as 'special legislation' does not

seem to us to take sufficient account of the equities of the case. The men who established the phosphate industry in the West, acting on the past decisions of the Land Office, pinned their faith to placer locations. If possible legally, their rights should be preserved as against later comers. Aside from this, and as a matter of broad public policy, there can be no doubt of the inadvisability of laying a basis for claiming extralateral rights on deposits that occur as beds and underlie many square miles.

Institute Meetings and Policies

The Canadian Mining Institute has come to have an enviable reputation both for solid worth and for the enjoyable character of its annual meetings. That held at Montreal early this month was evidently up to the standard set by its predecessors. We publish this week a lively account of the session written by an eminent American engineer who pays deserved tribute to the excellent program and entertainment. Incidentally he criticizes the American Institute of Mining Engineers and contrasts unfavorably the present meetings of the latter society with those held when, like the Canadian Institute of the present, both the American Institute and its members were filled with the fire of youth.

It is proverbial that beginnings are accompanied by great displays of energy and enthusiasm; the problem is to conserve some of this for later years when success brings size and responsibility. In this the Canadians have done better than have those of us who live south of the line. It will not do to credit this altogether to the fact that Canada itself is suffused with the spirit of youth, and the number of Canadian mining engineers is as yet so small as to permit of a larger measure of personal contact than between their brethren in the United States. These are powerful influences, but thoughtful planning, open-mindedness, and a touch of opportunism have contributed to the result. The Canadian Institute has more direct influence in governmental matters relating to mines than does the American Institute. This is because it has sought instead of refused responsibilities, rather than because of any difference in the character of the membership. The leaders of the American Institute have selected from among its possible fields one that is large and useful, but it does not include any attempt to influence the course of State or National legislation. Whether this be wise or not is a matter about which responsible opinions differ; but not having sought or accepted responsibility, the Institute has not acquired, or even held, a certain influence that should belong to it by right. In the conduct of the American Institute there are many things concerning which its members differ. It is useless to deny that there is much quiet criticism. Some of it we think justified. Our critic, however, writes with a caustic pen and we, among others, would not follow him the whole route. The large membership of the Institute we believe is a source of strength rather than of weakness; and as to excursions, we take with gratitude what the Gods and the management give, and regret only that professional duties too often prevent participation. It is true, however, that the annual meetings of the American Institute have become unimportant and formal. That this is not necessarily the consequence of a large, miscellaneous, and geographically scattered membership, is shown by the experience of the American Chemical Society. Neither is it a necessary consequence of the policy of opening the program only to professional papers, as is proved by the large and enthusiastic meetings of the American Society of Mechanical Engineers. Some way should be found, without disturbing the excellent work already being done by the Institute, to give to its annual meetings something of the admirable character of those of the other societies mentioned. We regret exceedingly that it is impossible to discuss the subject without seeming to pass criticism upon the eminent and much-loved secretary who has guided the Institute through so many years. His ability, his character, and the great sacrifices that Dr. R. W. Raymond has made for the Institute, demand that criticism of its conduct should not be lightly passed. That his policy has been generally sound, is the sense of the members as we know it, and has been proved by results; but it does not follow that improvement can not be made. The Institute belongs to its members. If they want a change of policy it is their privilege to enforce one. If they are interested in the meetings, the latter will become interesting; and it will not do to rest solely on the reverse of the rule. As members we can not fairly throw the whole burden on the secretary and then complain of the policy followed.

Yellow Journalism

The irresponsible character of certain portions of the daily press in America was never better illustrated than during the past week. The movement of a regiment or two to the Hawaiian Islands, in the course of ordinary transfer of troops from one point to another, was featured as a move by the War Department to meet a threatened attack by Japan. The silliness of this is only excelled by the potentialities for harm that it possesses. The severest critic of our War Department would scarcely go so far as to accuse it of being so footless as to send a mere handful of troops to repel an invasion, and no better way to precipitate a clash could be devised than the making of inadequate preparations for it. Japan possesses a press almost as irresponsible as our own, though more intelligently patriotic, and the constant agitation of such matters may at any time give rise to a situation as tense as that produced by the first blundering attempts at the regulation of Japanese immigration. The spectacle of a press so unintelligent and so unpatriotic as to deliberately incite international friction and imperil international relations for the sake of sensational news, is almost enough to make us wish for a censorship of Russian rigidity. Back of it all lies the fact that the hegemony of the Pacific presents a problem of pressing interest, and in a later issue we will discuss it more at length.

Pay-Streaks at Nome

By T. M. Gibson

Anvil Peak is a dome-shaped hill lying about four miles due north of Nome and rising to an elevation of 1050 feet above sea-level. If one should draw a circle of a five-mile radius with this peak as the centre, he would include an area that has already produced more than $50,000,000 in placer gold, and probably contains as much more, most of it awaiting improved and more economical methods of mining and more scientific methods of gold-saving to turn it to profitable account. This area includes the richest portions of the present and ancient beaches, all of Anvil creek and its old channels, Rock, Glacier, Dexter, and Dry creeks, with their old channels, Little creek, Center creek, Wonder creek, Holyoke, Bourbon, Newton, Otter, McDonald, and Tripple creeks, that portion of Nome and Snake rivers south of the foothills, and the vast body of tundra-covered gravel over which these several streams find their way from the foothills to the sea.

Map of Alaska.

The beach deposits at Nome have been the most important placers of their kind ever discovered. Nowhere else have the waves of the sea concentrated so much gold in so limited an area. There are now seven well recognized horizons between the foothills and the sea upon which surf-concentration has been carried on. Drill-prospecting through the ice, off shore, at the west end of Nome, has shown what appears to be another beach deposit 45 ft. lower than the present level of the sea. These beaches are known as the 'present beach', 'second beach', 'submarine beach', 'intermediate beach', 'Monroeville beach', 'third beach', and 'fourth beach'. The latest discovery is referred to as the 'offshore beach'. Their relative positions may be seen in the accompanying map and diagram.

The third beach was much the richest of them all, and the present beach was next in importance. The fourth beach has not, so far, shown any workable deposits, although a well defined shore-line, and having as large a body of surf-worn material as any of the beaches. All these beaches are more or less parallel with the present shore-line, and each lies on a plane sloping gently toward the sea. The present beach pay-streak lies wholly on a 'false bottom' which is usually clay or fine micaceous and sandy sediment, though sometimes there is no impervious parting layer between it and the underlying coarse coastal-plain gravel. Nevertheless, the gold does not penetrate below the average horizon, and the gold tenor does not seem to be affected by the absence of this impervious bed. The true bedrock, though varying somewhat, is approximately 45 ft. beneath the 'false bottom.' The surf-worn pebbles and sand are distributed over a width of 150 to 300 ft. from the shore-line at low tide and are walled in on the land side by a bank of gravel, muck, and tundra rising 10 to 20 ft. The beach deposit is usually from 7 to 9 ft. thick near the centre, and thins to about half this thickness both toward the water and toward the land. The thinning to landward is due to a steeper inclination of the inshore side of the 'false bottom,' while the surface inclination remains uniform; and a more gentle slope of the seaward side of the 'false bottom' relative to the surface, produces a like effect near the water's edge. Gold is present throughout the mass, but the pay-streak proper is usually within the first foot to two feet next above the 'false bottom,' and sometimes, even where it is richest, is confined to two or three inches lying on the 'false bottom.' This concentration is not uniform over the beach plane, but is richest on two and sometimes three horizons, as if representing high, mean, and low tide concentrations.

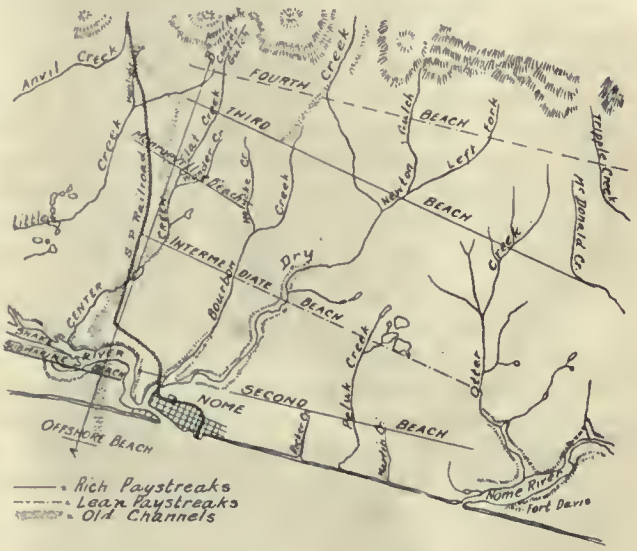
It is, however, more probable that it is due to seasonal variations in the water-level, consequent upon variable intensity of storms and direction of prevailing winds. These rich concentrations are lens-shaped deposits, usually 5 to 6 ft. in width, from 2 to 6 in. thick in the centre, and thinning to an edge both seaward and landward. In this respect they resemble in shape the beach deposit as a whole. Their extension parallel with the shore-line is always greater than their width, and is usually six to ten times as great. They taper to a rounded point at the ends. Near the ends, at either a slightly lower or higher elevation, another lens begins, and so makes the rich streak fairly continuous. These lenses consist very largely of magnetite and garnet sand, and in places have been so rich in gold as to tinge the bottom layer yellow. Five

hundred to one thousand dollars per day was taken from such spots with a single rocker.

The deposit as a whole consists largely of quartz sand and rounded quartz pebbles, with a moderate percentage of schist and limestone fragments, forming shingle. Probably 10% of the entire deposit is garnet sand, locally called 'ruby sand', and about 2% is black sand, which is largely magnetite. There are present also limonite, hematite, ilmenite, scheelite, and pyrite in small quantities. The deposit is stratified into layers, from an inch or less to a foot or more in thickness, the constituent particles being of varying degrees of fineness. The heavy minerals, while present in the uppermost, show an increasing percentage with depth, until near the 'false bottom' they sometimes make 90% or more of the mass. The beach was discovered to be gold bearing in the summer of '99 and more than a million dollars worth of gold was rocked and panned from it before the close of that season. Since, within the maritime limit of 60 ft. above mean high tide, no claims were allowed to be staked, it was open to every man to help himself to any spot not actually occupied by another. Lawyers laid down their briefs and doctors their medicine-cases, and, each procuring a rocker, hurried to find an opening in the line of human bees stretched along the beach, where he could set down his plant and have elbow room to use his dipper. Wages of $15 per day were offered for shovelers by claim-owners on the nearby creeks, but none could be had. The man who did not rock out $50 or more per day moved on to find a better spot. The inevitable result of this work was to hurry over a great deal of ground, rooting for the richest streaks and leaving many virgin spots between their pits. Though much of this rich territory has been gone over a second time, and some even a third time, using sluice-boxes and riffles or matting, there still remains a large amount of gold in the present beach which could be mined at a profit if one could get title to, or control over, a large area, and would install a plant with proper gold-saving appliances to handle the material by mechanical means, so as to reduce the labor cost to a minimum. The total output to the present time is estimated to be something over $2,000,000. A few outfits of two to five men each, with a line of sluice-boxes, a small gasoline engine and centrifugal pump may be seen scattered here and there along the beach every summer, but the yield from such work is just about equivalent to the wages paid.

The second beach lies about a half-mile inland from the present beach and at an elevation of 37 ft. above sea-level. It was discovered in the summer of 1902 at Pelnk creek, about two miles east of Nome, and was soon traced both east and west for several miles. It is nearly parallel with the present beach, but gradually converges upon it, both east and west from the point where first discovered. At Hastings creek, nine miles east of Nome, it is less than a quarter of a mile from the present beach, and at Penny river, ten miles west of Nome, it is about the same distance. It lies upon a 'false bottom' of sandy and micaceous sediment, locally called 'quicksand'. This quicksand is usually from 3 to 5 ft. thick at the upper side and thins down to an edge at the lower side. It is not always present under the pay-gravel, and where it fails the pay-streak lies on the coarse wash of the coastal plain. This beach is next in age to the present beach, and the deposit is of very similar character. It is, however, buried under 15 to 20 feet of overburden, except where crossed by the tundra streams, which in some cases have cut it away entirely within their valleys and in other cases have reduced the overburden to nothing or only a few feet. The overburden consists for the most part of bluish and black muck and decayed vegetation. Logs of drift-wood are quite commonly found near the upper edge of the beach, and these are frequently in a good state of preservation. A layer of peat from six inches to a foot thick is spread over the beach sand in some places, and this, when dried, burns fairly well in stoves.

The whole deposit is permanently frozen except



Beaches at Nome.

in the creek beds and a few isolated areas which, probably, are on subterranean drainage-ways. In Pelnk creek, where the beach was discovered, it was thought by Messrs. Bell and Dugan, who owned the creek claim which it crossed, to be a creek placer. While the first small pit was being opened I visited it and recognized its true character. This claim with others I soon after purchased for myself and my associates, and the first important operations conducted on this pay-streak were under my supervision. The second beach was by no means as rich as the present beach, but pans of 50 cents to $1 were commonly taken from the bottom six inches of the streak. The gold was of bright yellow color and amalgamated freely. Much of it was quite fine and difficult to save. Because of its flaky character it was carried through the sluices in suspension. After some experimenting, much of this loss was obviated by the use of a wide undercurrent with a series of drops and with carefully prepared plates. In a short stretch of the beach on the west side of Otter

creek from which more than $75,000 worth of gold was mined, approximately 25% of the gold was in pieces about the size and shape of gourd seeds. These were much in demand by the local jewelers for making nugget chains and other jewelry, and were sold for $3 to $4 per ounce more than they were worth when melted. Nowhere else in the district has gold of this character been found. On the inland side of this area, and only a few hundred feet distant, there is a ridge of schist bedrock which rises above the second beach-level and it is believed that veins in this schist are the source of these peculiar gold nuggets. Elsewhere throughout its length the gold was of the usual fineness of Nome beach gold, ranging from eight or ten colors to as many as two or three hundred colors to the cent.

The output from the second beach to date has been about $600,000. There still remains considerable unworked ground on this pay-streak, both east and west of Nome, but the richer parts of it have been exhausted.

The submarine beach lies almost directly under the second beach and at an elevation 56 feet lower. It is thus 19 ft. beneath the present sea-level, and its name is derived from this fact. It was discovered in the latter part of the summer of 1907 at a point about one mile west of Nome. It has been explored and definitely traced in a westerly direction about two miles from the point where it was discovered. About three-quarters of a mile to the eastward from this point, mining operations have disclosed deposits in the valley of Dry creek near the same level, and these are believed to be on the easterly extension of this old shore-line. The true bedrock surface is undulating, and where high, the beach deposit lies on it, while in the depressions it lies on a 'false bottom' of clay, sand, and gravel varying in thickness with the depth of the depression, the result being that the deposit lies on a gently sloping plane at a constant elevation, though sometimes as much as 10 to 12 ft. above true bedrock. It is overlain by 50 to 55 ft. of sand, clay, and gravel and 10 to 15 ft. of muck and tundra. Both the overburden and the beach deposit are permanently frozen. The pay-gravel is from 1 ft. or less to about 3 ft. in thickness, and the gold is quite uniformly distributed through it. It is never found highly concentrated in a thin layer on the bottom as was commonly the case in the present beach and the third beach, and less frequently on the second beach. It differs from these, also, in the character and quantity of the predominant heavy minerals associated with the gold. The most abundant heavy minerals are pyrite and arseno-pyrite. Garnets are common, but no well sorted layers of 'ruby sand' occur as in the other beaches, and the garnetiferous particles are of much larger average size. Magnetite and ilmenite also occur sparingly. The gold is of a bright yellow color and averages fairly coarse for beach gold, so that a close saving is made in ordinary sluices. The beach deposit is 300 to 400 ft. wide, and the bedrock slope is usually less than 2%. The gold tenor is from about $4 to $10 per cubic yard. The thinness of the pay-streak and a heavy, treacherous roof make mining difficult and expensive, and there have been at least as many failures as successes in the efforts that have been made to mine it. The total production to this time is approximately $300,000. There is still a large bedrock area to be mined within the proved territory, and there is a possibility of extension both east and west from the present known limits, but the poor showing so far made does not encourage exploitation. Its thickest and best bodies of pay are in the area where it was first discovered, and this, as I shall show elsewhere, is probably due to the old Anvil creek channel. This deposit is interesting as being the oldest of the known beaches in this district. It has been determined by the Geological Survey to be at least as old as the Pliocene.

The intermediate beach lies about one and three-quarters miles inland from the present beach. It was discovered during the winter of 1905-6 just east of where it passes under Center creek. It lies on the true bedrock and is 21 ft. above sea-level. This beach deposit is from 400 to 600 ft. wide and has been definitely traced from a point about a quarter of a mile west of Center creek eastward to Dry creek a distance of one and a half miles. Beach gravels on approximately the same level, and on an easterly extension of this line, have been disclosed in various prospect-shafts covering a distance of about six miles, but as none of these has shown workable deposits, they have not been definitely connected with the payable area. This deposit is peculiar, however, in having been the habitat of a numerous family of mollusks of the clam variety, and their shells are so abundant that it is often called the 'clamshell' beach. These shells are present in many of the prospect workings to the east and thus serve to identify it. The area that has shown workable deposits lies from about a quarter of a mile west of Center creek eastward to Bourbon creek a distance of about one mile. The widest pay-zone and richest gravels are in the vicinity of Center creek. The pay-streak is from 1 ft. or less to 3 ft. thick, and is easily distinguished from the overlying unpayable sand and gravel by the great quantity of clam shells that lie in the pay-zone. The total thickness of the surf-worn material is usually from 6 to 12 ft. The gold tenor is from $5 to $15 per cubic yard of pay-streak. The bedrock has an undulating surface, and the gold frequently penetrates the seams and crevices to a depth of a foot or more in the high points. The bedrock slope to seaward is very gentle, being usually about 1 ft. to 100 ft., or 1%. The average size of the pebbles is less than in the other beaches, and the proportion of fine sand greater. Garnet sand occurs much more sparingly than in the present or second beaches. Pyrite, arseno-pyrite, magnetite, and ilmenite are present in small quantities. The gold is bright yellow, and the particles will run from 8 or 10 to 200 or more to the cent. The gross output from the pay-streak to date is about $800,000. There still remains a large bedrock area of unworked ground along this old shore-line, but the pay-streak

is thin and the gold tenor too close to actual working costs to make the field attractive under present conditions. The deposit is overlain by 35 to 45 ft. of muck, sand, and gravel, all of which, including the pay-streak, is permanently frozen.

The third beach, so called because it was the third deposit of this character found near Nome, lies about three miles inland from the present beach and at an elevation of 70 ft. above sea-level. It was discovered near Little creek in the winter of 1904-5. It is a crescent-shaped line skirting the foothills back of Nome and converging toward the sea at Cape Nome on the east and Cape Rodney on the west. It has been definitely traced a distance of 15 miles from Sunset creek on the west to Hastings creek on the east. This stretch includes both Nome and Snake River valleys, and both have been eroded below the level of the beach. The gap thus made by the Snake valley extends from Little creek westward to near Sunset creek, and covers about five miles. In the Nome valley the gap is from McDonald creek to a point about a half-mile west of Irene creek, and covers two and a half miles. From Little creek to Dry creek, a distance of two miles, this pay-streak, including the so-called 'Slough-Over' pay-streak, which lies just under the south rim of the upper plane, has produced $9,865,000, and, from Dry creek to McDonald creek, a distance of three miles, $2,148,000. East of Nome river, from the neighborhood of Irene creek eastward for one mile, the output has been approximately $400,000, and west of Snake river approximately $175,000, making a total so far produced from this beach of about $12,588,000. The area between Little creek and McDonald creek is nearing exhaustion, the unworked portion being chiefly on the lower or 'Slough-Over' streak, with a few blocks of thawed ground on the main pay-streak. From Hastings creek westward, about two miles of beach-line remain unworked, but this portion is very low grade. West of Snake river no deposits remain which are known to be of workable value.

From Little creek eastward for three and a half miles the deposits lie on true bedrock which is mostly a black, slaty schist or phyllite with occasional narrow belts of limestone. Beyond this point the bedrock surface slopes gently to the eastward, and at McDonald creek, one and a half miles farther east, is 20 ft. below the beach-level. Continuing eastward, it drops 25 ft. more in the next mile and a half, and here Nome river has cut a V-shaped trough in the old valley floor about 50 ft. below sea-level. On the east side of the river the bedrock rises to within 12 ft. of the beach-level at Irene creek, one mile distant, and a half-mile farther east drops rapidly to at least 30 ft. below sea-level, and does not rise above sea-level until approaching the range of hills back of Cape Nome and east of Hastings creek. From the point near Otter creek where the bedrock surface dips below the beach-level, on to the eastward the beach lies on a 'false bottom' of fine sandy sediment, similar to that which underlies the second beach. It is of light-gray color and contains much mica in small thin scales. It lies only under the surf-line, and is 5 to 7 ft. thick at the high-tide line, breaking abruptly against gravels and coarser sands, and thins down to nothing and disappears at the lower rim of the beach. The material lying between this 'false bottom' and true bedrock, as shown by various shafts and drill-holes, appears to consist for the most part of stratified beds of marine gravels, sands, and silts. I have had unusual opportunity to ascertain the physical conditions that prevail along this famous pay-streak, as I have been identified with its development from the beginning, and have, for myself, and as manager of the Wild Goose Mining & Trading Co., been directly in charge of the mining operations covering more than one-third of the entire area mined to this date; and, in addition, have extended exploration, by shafts and drilling, much beyond these limits. This pay-streak is overlain by 20 to 120 ft. of overburden, being shallow in the valleys of the tundra streams and deep in the ridges that lie between them.

At the surface there is from a thin sheet to as much as 15 ft. of tundra vegetable matter and bluish and black muck. This is underlain by well-washed gravels and sand with beds of clay and silt. In some areas the clay and finer sediments are entirely absent, and again they make the major part of the deposit. It is interesting to note that the gravels are invariably gold-bearing, and in that portion lying between Little creek and Dry creek some shafts have shown an average gold tenor of between 25 and 50 cents per cubic yard in 40 to 50 ft. of gravel. The beach deposit is from 5 or 6 to about 12 ft. thick, and, including the lower or 'Slough-Over' pay-streak, is 300 to 600 ft. wide. There is often a barren zone between the lower and the upper pay-streaks, and this is sometimes 100 ft. or more in width. The gold in the 'Slough-Over' pay-streak has been concentrated on the seaward side of a bar that formed just off-shore. At extreme low tide a narrow lagoon existed between the two shore-lines, and this dead-water area is now the barren zone. The upper pay-streak is always much richer than the lower, and where the upper is lean the lower fails altogether. In such rich claims as the Portland, Three Star, Bessie, May Fraction, Cyrus Noble, and Bear Cub, the 'Slough-Over' is rich, but many claims lying between these and to the east and west, with leaner pay on the upper plane, have either a very lean 'Slough-Over' pay-streak or none at all. In the upper pay-streak the beach plane proper is about 100 ft. in width. There is usually an abrupt drop of 1 or 2 ft. at the lower rim of this plane. Lying immediately below this, and built up as high or higher than the edge of the rim, there is a zone of cannon-ball boulders of quartz, varying from the size of a baseball to 6 or 8 inches diameter and usually covering a width of about 20 ft. These are either marble-like in roundness or of oblate spheroidal shape, and the deposit is peculiar in that it often looks as if piled by hand; the interstices not being filled by sand and sediment as one would expect them to be.

(*To be continued.*)

History of the Homestake Lockout

By An Occasional Correspondent

The painstaking thoroughness and attention to detail which marks all of the Homestake company's undertakings was well exemplified in the way it handled the labor difficulties at its big South Dakota property a year ago. Trouble appeared to be in the air. There were rumors of war and impending difficulties early in the fall of 1909. The Western Federation of Miners was making a strong campaign for membership in its Lead City and Central City unions. Nearly all the members were Homestake employees. In October it became apparent that the Federation meant business. Membership was being solicited as never before in the history of the unions, and big mass-meetings gave evidence of the increase that was resulting from their efforts. Finally in order to clinch the matter the following notice was published by the unions on October 10:

Notice

Resolved, That we demand of all ex-members who are now in arrears, that they shall at once re-instate and place themselves in good standing in our union and that we demand and require all eligible men who are employed within our jurisdiction, to at once obtain cards certifying their membership in the proper local of the Western Federation of Miners.

Resolved, That any and all men within our jurisdiction who shall see fit to neglect or ignore these just demands and requirements, shall be dealt with in the near future accordingly as we may determine to act in each of their respective cases.

Lead City Miners' Union.
Central City Miners' Union.

Fifteen days later, or under date of October 25, the following self-explanatory resolution was given to the Lead City papers for publication:

At a mass meeting of the members of the Western Federation of Miners, held at Lead Miners' Union Opera House on Sunday afternoon, October 24, the following resolutions were adopted by a unanimous vote:

Whereas, A resolution adopted on October 10, calling upon all workers in the jurisdiction to join the W. F. of M. has been quite generally complied with, therefore be it

Resolved, By us, the members of Lead City Miners' Union No. 2, W. F. of M., and Central City Miners' Union No. 3, W. F. of M., in joint session assembled, that all men neglecting or refusing to become members in good standing of the local in whose jurisdiction they may be working on or before November 25, will be declared unfair to the W. F. of M.; and be it further

Resolved, That we, the members of the aforesaid unions, refuse to work with any and all men who become unfair to our organization by or through refusing to comply with the provisions of this resolution.

Central City Miners' Union No. 3, W. F. of M.
Lead City Miners' Union No 3, W. F. of M.

The publication of this resolution caused a generous number of men to join the unions, and to make it easy for those who were not in good financial shape to signify their intention of joining as soon as able, emissaries of the union issued a large number of the following cards:

Card

This card entitles the bearer, Mr. ....., who has worked in this camp for a period not to exceed 45 days, the privilege of working by the side of a man with a paid-up card until such time as he shall have had one pay day; after which time he hereby agrees to relinquish this card and be properly initiated into this, the Lead City Miners' Union No. 2, W. F. of M.

Name .....

Dated November 9, 1909.

Void after December 25, 1909.

In the face of all of these evidences of the intention of the Federation to thoroughly unionize the mine, speculation was rife as to the course the Homestake company would pursue. Knowing the general policy of the Federation, it was generally believed the company would refuse to recognize the union. Others believed that when the men showed the solid front it was expected they would present on November 25, the company would capitulate, and grant all demands. On November 17 the question was settled once and for all by the publication of the following notice, which, it may be remarked in passing, is still running in the *Lead Daily Call*, giving evidence of the company's intention to live up to it to the letter:

Notice

November 17, 1909.

Notice is hereby given that the Homestake Mining Company will employ only non-union men after January 1, 1910. The present scale of wages and the eight (8) hour shift will be maintained. All employees who desire to remain in the company's service must register at the General Office of the company on or before December 15, 1909.

T. J. Grier, Superintendent.

The publication of this notice acted like the explosion of a bomb-shell in the union camp. The officials immediately sought interviews with Mr. Grier. They were courteously informed that the notice meant absolutely what it said—not a word could be spared or added, if thus its meaning would be changed one iota. The Federationists presented a solid front, and said they would force the company to come to time. Trouble was on. The biggest gold mining company in the West had locked horns with the Western Federation. The one was as unyielding as the other. The eyes of the entire mining world were turned upon Lead City, as the victorious one in the fight would have good cause to be proud. Worthy foes were matched—a great mining company and a powerful union.

Much breath was expended in trying to show Mr. Grier the error of his way in refusing to recognize a union that numbered an overwhelming majority of his employees, but it was of no avail. His mind was made up, and made up to stay. On the evening of November 21, a strike was voted by the unions, the matter being referred to the executive board of the Western Federation, at Denver, for approval. The company's answer was a lockout.

The result was that on the evening of November 24, the day before the union resolution was to take effect, there was no night shift employed in mine or mill; men were laid off by the hundred, and for the first time in its history, the mills containing a thousand stamps were idle through a difference between

employer and employee. Next day a crew of the men who proposed to stick by the company was employed in pulling pumps, removing air-drills, motors, tools, and all perishable machinery from the mine, dismantling air-compressors, engines, and surface machinery, covering the whole with a generous coat of white lead to prevent rust. So thoroughly was this work done that it is stated the mines could have remained idle for years and no harm would have come to the expensive machinery with which the wonderful plant is equipped.

Having shut down, and shut down thoroughly, everything except work on the hydro-electric plant on the Spearfish river and the pumping-station at Hanna, where water is secured for the mills as well as the domestic supply of Lead and Deadwood, the company proceeded to play a waiting game. The property was fully guarded by posses of Pinkerton, International, and Thiel Agency men, and men who wanted to work for the Homestake. Dead-lines were established, and to cross one of them at any hour of day or night meant that one would be accosted by a burly man equipped with two or three miniature cannon. Meanwhile the company offices were doing business with men who were signing the following card, which, by the way, is still used:

Card

I am not a member of any labor union, and in consideration of my being employed by the Homestake Mining Company agree that I will not become such while in its service.

.....

Department .....

Occupation .....

In some manner the *Daily Register*, organ of the Federation, secured the names of a number of those who had 'signed up' with the company. The *Register* called them traitors to the cause of unionism and threatened to publish their names. This was done. Forty-nine men were on the first list published by the *Register*. Not only did the list appear in the paper, but it was printed on cards and tacked up on telephone poles, in public gathering places, and saloons. This action, really meant to discredit and cast odium on the men named, had a most disastrous effect, at least from a union standpoint. George B. McClellan, one of the 'forty-niners,' called a meeting of those whose names were placarded. They met once or twice and evolved a plan of an organization named the 'Homestake Loyal Legion.' A big meeting was held in Society Hall, Lead. Speeches were made by McClellan and others, and representatives of the company pledged protection to all men who would work. Intense enthusiasm prevailed, and the net result was that in three days the Loyal Legion was thousands strong. Its membership was not limited to workingmen, but included doctors, lawyers, merchants, and professional men who sympathized with the company.

Thus was the backbone of the strike broken. The Homestake Loyal Legion in three days solved the question, and by January 9, when the first shift went to work, the company had the sympathy and moral support of more than half of the camp. From the time of the resumption of work in a small way on January 9, until full capacity was reached on March 3, it was merely a question of securing the men. Employees were recruited from the lead mines of Missouri, Kansas, and Wisconsin, from the iron and copper mines of Michigan and Tennessee, from the gold mines of Colorado—in fact, from all over the United States. For several months it was necessary to practise elimination. In gathering a crew of nearly three thousand men, it was but natural that many idlers came to Lead. These have been gradually weeded out, until today the Homestake army is a body of sober, industrious Americans. The absence of foreigners is noticeable, whereas prior to the shutdown a large percentage of the employees were foreign-born. They included in their numbers Slavonians, Italians, and Greeks, the lowest classes of southern Europe. The change to Americans is reflected in greatly improved business conditions in Lead.

To cement the relations between employer and employee, the company established the 'Homestake Employees' Aid Fund' during the summer. Each employee contributes one dollar per month, and the company gives one thousand dollars. For sickness or disability through accident, one dollar a day is paid during the time of lay-off. For serious accidents—loss of foot, hand, or eye, $400 is paid. For total disability (loss of both hands, feet, or eyes), insanity, or death, $800 is paid. The fund has been in operation several months and has been entirely successful. T. J. Grier is treasurer, without salary (as are all other officers of the Fund), and all clerical work is done in the Homestake office without expense to the Fund. With such an organization to promote friendship between the company and its men, and the sincerity of the company's purpose attested by a substantial monthly contribution, a healthy condition is reflected. The Homestake won its fight with the Western Federation of Miners, and is keeping its men good-humored by treating them fairly. It will undoubtedly be years, if ever, before the Homestake has another serious disagreement with its employees.

The whereabouts of the Ophir of the Bible is as much a mystery today as it was 200 years ago. African travelers point out several localities as the ancient Ophir, each giving 'conclusive proof' of the correctness of his theory. Some profess to believe that Ophir was in Korea, and these also have convincing data to back their opinions. The fact is, no one as yet has been able to find an Ophir that is satisfactory to everybody. An ancient atlas, published in Amsterdam in 1705, describes a region south of the Zambesi river in South Africa as the undoubted Ophir of Solomon. There are the ancient ruins, the placer mines, and the old underground workings; but there are similar places elsewhere in Africa north of the Zambesi river, so the real situation of the original Ophir remains as great a mystery as ever, with no promise that it will soon be known.

The Corona Giant Blast

By G. B. Street

On Saturday, March 11, the Corona Rock Co. set off a most successful blast at its quarry at Corona, California, under the direction of Mr. A. H. Crane, a powder expert in the employ of the E. I. du Pont de Nemours Powder Co., of Wilmington, Delaware. The blast was for the purpose of obtaining rock for street-railway work, concrete, and street-paving, and was planned so well that the larger part of the 130,000

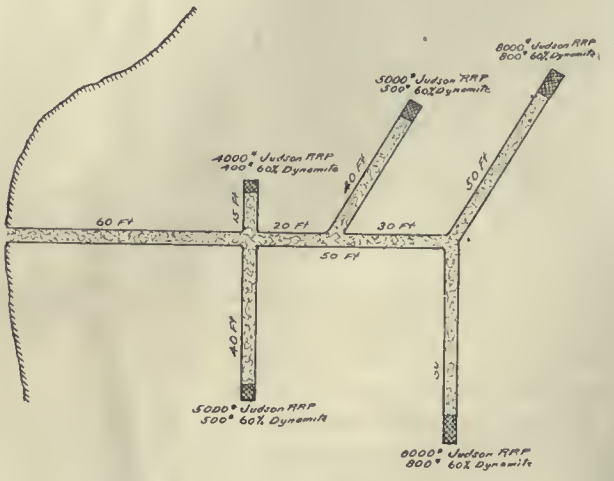


Fig. 1. Plan.

tons of rock broken will go to the crusher without any further preliminary breaking.

The rock appears to be a trachyte and is blocky and very tough, so that the most careful judgment was required in arranging the explosives in order to get the maximum amount of fine material and to avoid scattering the broken rock. Having only 80 ft. of overburden made the problem more difficult.

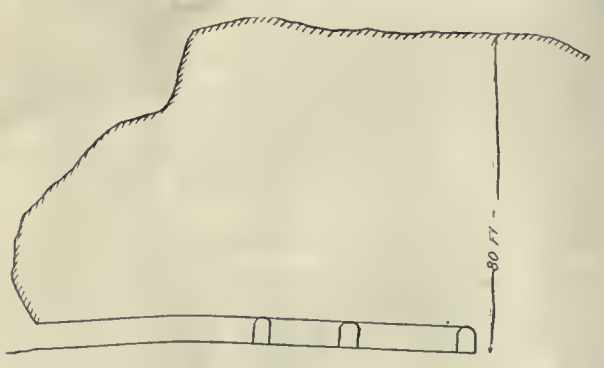

Fig. 2. Section.

The explosives used were 30,000 pounds of Judson R. R. P. powder and 3000 lb. of 60% dynamite. Judson R. R. P. is a special powder adapted for large blasts and is efficient in this class of work, as its action is quicker than ordinary blasting powder and slower than dynamite. The 60% dynamite is used to detonate the Judson R. R. P. powder, which furnishes the force to shatter the rock. The quantity of explosive used and the proportion of dynamite must be carefully estimated in each case, taking into consideration the height of overburden, the contour of the hill, the formation of the rock, and the quantity and quality of material desired. Fig. 1, 2, 3, and 4 show the plan of the preliminary exeavations and the method of placing the explosives and fuses; they are self-explanatory.

The greatest care was taken in placing the explosives, both on aeeonnt of safety and to avoid any deterioration of the powder by absorption of moisture. The laborers who stowed away the powder in the cross-cuts were first carefully searched for matches or anything else that might possibly generate a spark or flame in the neighborhood of the powder, and they were made to wear rubber shoes or else wrap their feet in gunny sacks or some similar material. Electric torches were used in place of lanterns or candles to furnish light in the tunnel, for

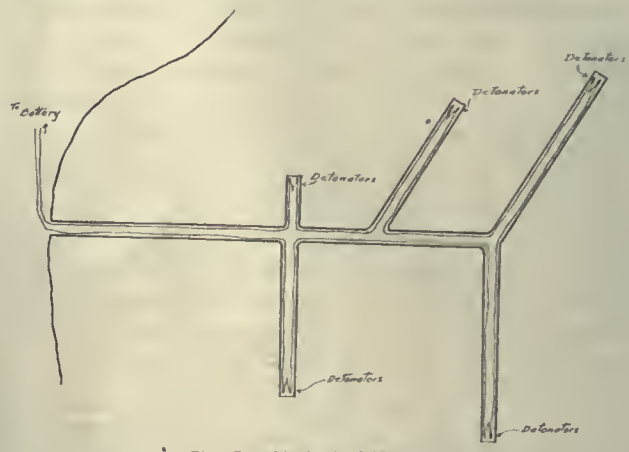

Fig. 3. Method of Wiring.

the same reason. When the above precautions are taken there is, contrary to the general opinion, no danger in handling even such a large quantity of explosives. The charge was fired by electricity, as in a blast of this character it is absolutely essential that all the powder be detonated at the same instant. Two specially-constructed detonators were placed in the dynamite in each cross-cut and all connected up in series. Each fuse was tested with a galvanometer before placing it in the dynamite, and each connection was similarly tested to make sure that there was no break in the circuit. The connecting wires were carefully laid on the floor of the cross-cuts and main adit, and covered with sand or fine gravel to

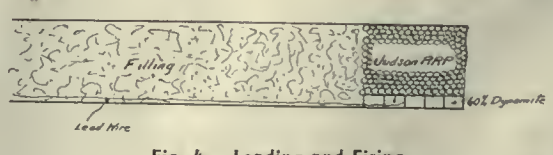

Fig. 4. Loading and Firing.

prevent damage. After the wires were strung to the portal of the adit and covered they were again tested with the galvanometer, and this test was repeated at frequent intervals during the loading and filling of the tunnel. The galvanometer used was one that is manufactured for the special purpose of testing the wiring and connections in a circuit used for electric detonation. The galvanometer reads in ohms, and shows the actual resistance between connections. Therefore, if the reading on the galvanometer, when connected to the wires at the mouth of the tunnel, did not equal the sum of the readings made when connected separately to each fuse with

its lead-wire, it would indicate a short-circuit or poor connection. On the other hand, a break in the circuit is indicated by no movement whatever of the galvanometer needle. Either fault may be readily found and corrected by the proper use of the galvanometer.

The firing was done by an electric current generated in a wound magneto, operated by hand, and placed at a sufficient distance from the adit for the operator to be out of danger from flying rocks. The lead-wires were tested with the galvanometer for the last time just before connecting to the magneto battery. When this final reading of the galvanometer is correct, there is absolutely no possibility of a failure of the blast. The correct voltage and amperage must be used, as otherwise there would be no detonation. If the voltage and amperage are too high the wires will be burned out, and if too low there will not be enough current to set off the fuse, and in either case there will be no explosion. At the same instant that the operator pushed down the lever of the magneto battery the hill trembled, raised in the air a few feet, and fell forward as though it had been pushed by a giant force, leaving 130,000 tons of rock available for the crushers. Fig. 5 and 7 show the quarry face before the explosion, and Fig. 6 and 8 are taken from the same points immediately after the explosion. The thoroughly-broken character of the rock, and the water-tanks, standing unharmed close by, are features of special interest.

Fig. 5. Before Firing Blast.

Ore-feeders require no power to operate them. They are almost invariably actuated by blows from a tappet on a stamp-stem.

Canadian Mining Institute Meeting

By Our Special Correspondent

*The first session of the meeting was called to order at 10 a.m. on the morning of March 1, by the president, F. D. Adams, of Montreal. In the absence of the Provincial Premier, Sir Lomer Gouin, the address of welcome was delivered by the Hon. C. R. Devlin, an Irishman who quickly won his auditors by an honest cordiality seasoned with native wit. Mr. Devlin called attention to the practical usefulness of the Institute in public matters relating to mining and allied interests; that the Government of the Province of Quebec had had occasion to seek its counsel and advice in the selection of officials charged with technical duties and in the equipment and personnel of exploring expeditions. He intimated that his Government was likely, in the near future, to avail itself of such services even more frequently than ever before. Following this came the presidential address of Mr. Adams, annual report, and other matters relating to the Institute. The president's remarks were noteworthy for the'r good taste, appropriateness, and informing character concerning the development of the mining industry in the Dominion. Reports of mineral statistics for 1910 were presented by different provincial officials, and, while of interest to some persons, were as dreary as such documents usually are. Thomas W. Gibson, the Deputy Minister of Mines from Ontario, called

*Thirteenth annual meeting, Chateau Frontenac, Quebec, March 1 to 3, 1911.

attention to the decreased production of petroleum in Canada, especially in Ontaria, and the desirability of conserving the natural gas supply for domestic purposes. Mr. Gibson's remarks were eminently sensible and interesting.

Then followed a communication by L. Reineeke, of the Geological Survey of Canada, on 'The Ore Deposits of the Beaverdell, West Fork of Kettle River, B. C.' Wednesday afternoon was devoted to an excursion by electric car to the Montmorency Falls, with tea and luncheon at the Kent Inn of that place. Although the afternoon was stormy and the falls solidly frozen, the hospitality of our hosts more than compensated for the forbidding climatic conditions outside. Wednesday evening was devoted to a paper by our old friend, J. F. Kemp, of Columbia University, on 'The Engineering Problems of Geological Nature Afforded by the New Catskill Aqueduct of New York City,' in which he showed how useful the geologist may sometimes be to the civil engineer as well as to his more closely allied brother, the miner. Mr. Kemp was followed by A. E. Barlow, of Montreal, on 'The Economic Geology of the Chibougamou District.' Mr. Barlow won all hearts by his dry humor and good fellowship. His paper epitomized the results of the Quebec government expedition to this district last summer, and incidentally showed the good sense of Mr. Devlin, the Minister, in its despatch, for the results obtained by Mr. Barlow's party were most disappointing in view of the exaggerated reports that had previously come out from that country. Certainly no railroad building is justified as yet into that desolate region, cursed with a brutal climate, possessing poor timber, and indifferent mineral resources.

Copies of the preliminary report of the Commission were handed around at the meeting. On pages 13 and 14 of this document it is stated that, "the whole area examined by the Commission is of Archean or pre-Cambrian age. This, therefore, in common with other similar areas of our hinterland, is very promising from a mining geological standpoint. The large areas of Keewatin schists present precisely similar rock types as have been found associated with the gold of the Porcupine and Larder Lake gold districts in Ontario, while the geological relations so far as known are not dissimilar. In addition, the almost invariable presence of gold in the quartz and its occurrence over such a wide area, although usually in a small amount, is distinctly encouraging and should stimulate prospecting if the region was not so usually and deeply covered with peat and moss, and if it was not so remote from civilization and thus difficult of access. The sulphide deposits of Copper Point are also worthy of further development. This occurrence seems to have puzzled the earlier mining engineers at this place and under these conditions. None of the discoveries of copper and gold are in deposits of such magnitude or promise as would enable your Commission to state, without a considerable degree of hesitation, that they would with further development become 'mines' in the strict meaning of this term." The asbestos occurrences of which so much was expected were found to be essentially different from those at Thetford and Black Lake, "for whereas at these places the differentiation in the magma as shown by the various rock types extends to the most acid phases, and is therefore very complete, the most acid rock type noticed at Lake Chibougamou is only at most of intermediate composition as exemplified by the feldspathic dikes already mentioned as cutting the serpentine. * * * The deposits of iron ore (magnetite), which are perhaps large and more typically exposed on the southern face of Sorcerer mountain than elsewhere in the region, are not of any great importance at the present time."

Thursday morning's session was wholly occupied by the reading and discussion of papers relating to asbestos. As may not be generally known, the Province of Quebec possesses the most valuable deposits of this mineral in the world. The principal mines are situated at Thetford and Black Lake, about eighty miles south of Quebec on the line of the Quebec Central railroad. In 1910 this district produced asbestos to the value of $2,553,277, as compared with $2,317,052 in 1909, or probably about 85 to 90% of the world's entire production. The occurrence of this mineral is well described by John A. Dresser, of the Dominion Geological Survey.* This subject is of peculiar interest because of the comparative rareness of asbestos and the great industry which has been built up upon the mines of the Thetford district. Here there are associated with pre-Cambrian igneous and sedimentary rocks, isolated intrusions of granite, supposed to be of Devonian age. On the southeastern flank of the low range of hills composed of these rocks there are a series of basic intrusives with a northeast and southwest trend that are generally known as the Serpentine Belt. It is in this that the asbestos and chromite deposits of the eastern townships are found.

During the discussion of asbestos it was brought out that the Bell mine at Thetford worked all winter and much if not most of its mining was done underground. The cost of mining the 'mill rock' is about 50c. per ton; the milling cost varied from 50 to 80c. In other words, this work resembles mining of low-grade ore, and large quantities must be handled to make a profit. Considerable interesting divergence of opinion regarding the origin of asbestos developed during the discussion. According to A. E. Barlow, "asbestos or chrysotile is really a fibrous serpentine, a rock which in its purest form results from the alteration of olivine. The fresh rock is called dunite, and much of it is made up almost wholly of the mineral olivine, with sometimes a little chromic iron ore and pyroxene as accessory or accidental constituents. Olivine is very alterable in the presence of water, especially heated water, so that it is seldom that a perfectly fresh dunite is found. Thin sections under the microscope show all stages of this alteration as a result of the secondary action already described. The grains of olivine are converted into fibrous serpentine or chrysotile just around the edges and then along certain lines of fracture, which traverse the various individuals in

*Jour. Canadian Min. Inst., Vol. XIII.

different directions. This alteration proceeds until the whole individual is replaced by the secondary serpentine. Some of these small fractures filled with fibrous serpentine (veinlets) are very irregular in their development, while others follow certain well defined and more or less regular structural planes of the mineral. Now, if one of the microscopic thin sections is taken and studied, we have on a minute or microscopic scale what actually takes place on a larger scale in the working face of a quarry. We find, moreover, as Mr. Woolsey has so well pointed out in his paper, and as Mr. Dresser has emphasized, that the formation of asbestos really commences along a line, and extends outward from this as a centre. Again, most of the previous descriptions of this mineral, it is observed, give expression to the idea that the asbestos-bearing serpentine has undergone contraction, whereas the very reverse has been the case, and the secondary serpentine is really from 20 to 35% greater in volume than the original or fresh dunite from which it has been derived. The so-called veins are really cracks formed almost if not quite in place, and growing in direct proportion to the amount of magmatic water or granitic juice supplied in the later stages of their formation. The asbestos or chrysotile has not been transported from a distance, and has, therefore, in this respect no relationship with ordinary veins. These minerals owe their presence in such purity and abundance to the great purity of the original rock and the presence of an ample supply of magmatic waters, due to the pronounced differentiation of the whole rock mass, especially toward the acid or granitic types which is a marked and almost unique feature of the Thetford and Black Lake fields. * * * The commercial asbestos of Quebec, or chrysotile, as it is known to the mineralogist, is in reality the crystalline form of serpentine. It is the best attempt that serpentine can make in the way of crystallization, the various fibres being, perhaps, a greatly exaggerated form of the prismatic crystals. The large 'veins,' so-called, are but the giant form or expression of the minute fibrous serpentine. * * * If the asbestos is formed quietly, and with a minimum of motion, the longest, silky, uninterrupted 'cross' fibre is produced; whereas if the rock is subjected to violent and prolonged stretching or dislocation, abundant picrolite (the hornblende of the miners) or 'slip' fibre is produced. My first studies of picrolite of serpentine inclined me to the belief that this variety was really undeveloped asbestos. As a matter of fact it really represents both the under-developed and over-developed asbestos."*

The views of John A. Dresser, of the Dominion Geological Survey, appear to be similar to those of Mr. Barlow. His idea is that the original joint planes in the dunite rock were the source of many, if not most, of the asbestos veins. A careful examination of the fracture lines of the original rock frequently shows the beginnings of serpentinization, due to meteoric waters. According to Mr. Barlow, a fissure is not essential, the asbestos could begin to grow at a mere line or fine crack, and that this mineral owed its origin more to magmatic than to meteoric waters. Mr. Barlow appears to place more stress upon the action of magmatic waters than does Mr. Dresser, who emphasizes the potency of meteoric waters in the genesis of asbestos. Fritz Cirkel, of Montreal, differed quite markedly in his ideas in regard to the origin of asbestos. While perhaps I did not hear him distinctly, his opinions do not appear to have been based upon sound chemical and physical hypotheses. Mr. Cirkel does not believe the asbestos began to grow outward from a line, but must necessarily have been formed in a pre-existing fissure, the fibre or crystals growing out from each wall. All were agreed that asbestos is a derivative of serpentine, which in turn is an altered dunite. Mr. Cirkel spoke most entertainingly upon the occurrence of asbestos in the island of Cyprus, in South Africa, and in Siberia. He said the Siberian deposits resembled those north of Ottawa, which have been known and worked to some extent during the past twenty years, but have not been especially productive, as compared with the Quebec mines. An excellent paper was read by C. H. Richardson, of Syracuse, N. Y. on 'Asbestos Deposits of the New England States,' and another by J. S. Diller, U. S. Geological Survey, on the 'Types and Modes of Occurrence of Asbestos in the United States.' This was followed by a paper on 'Occurrences of Serpentine and Asbestos on the Beresovsky, Kamensky, and Monoten Estates in the Ural Mountains, Russia,' by V. J. Kryanaisky, St. Petersburg. This paper did not appear to have been well translated; certainly it was not especially interesting. The Russian asbestos is inferior and may be likened to shoddy as compared to the Quebec asbestos wool. This symposium was followed in the afternoon by an excellent paper on 'The Slate Industry in Southern Quebec,' by John A. Dresser, Geological Survey, Ottawa. Mr. Dresser recounted the difficulties in developing this industry, but seemed hopeful of its ultimate success. After Mr. Dresser, Mr. David T. Day, of Washington, discussed the 'Recent Developments in Petroleum in the United States.' He was followed in turn by Eugene Coste, of Toronto, on the 'Structural (Anticlinal?) Theory of Oil and Gas Deposits Explained by the Volcanic Origin of Petroleum.' As was to be expected, our Canadian friends exhibited but an academic interest in petroleum; their country as yet producing little, but possessing hopes for more. Mr. Coste's paper was chiefly a review of different theories respecting the origin of mineral oil, and its author suffered the penalty of his industry and good fellowship by having lots of fun poked at his theories. At this point the tobacco-smoke of the hall became unbearable to your correspondent, who being constrained to take a walk in the open, missed hearing several interesting papers that followed. Personally, I approve of smoking at these unconventional and masculine meetings, and join in the practice, but I must say the ventilation of the room on this and subsequent afternoons would have shamed that in a mine as deep as the source of Mr. Barlow's 'magmatic waters.'

The 'Smoking Concert' of Thursday evening was

*Jour. Canadian Min. Inst., Vol. XIII, pp. 439-441.

a delightfully informal affair, good cheer and sandwiches, interlarded with song, stimulated our bodies and lightened our minds. Once more our friend, Mr. Kemp, showed himself the possessor of versatility as well as a keen sense of fun. Friday morning and afternoon were devoted to the reading and discussions of papers. There was a refreshing spontaneity and seriousness in the discussions which was delightful, quite unlike the prosy meetings of some other societies, where papers are 'read by title.'

The annual dinner Friday evening at the Chateau Frontenac was the crowning event of this notable meeting. Here fun was mingled with eloquence, spiced with politics, and served to an essentially North American assemblage of men typical of much that is best and most substantial in our race. On the whole, this gathering of mining men forcibly reminded me of some of the meetings of the American Institute of Mining Engineers during its best days, 25 years ago; before conservatism and unwieldy membership of nobodies in mining swamped this organization. The Canadian Institute gatherings are essentially assemblages of men desirous of meeting and knowing others of similar tastes and occupations, not simply social gatherings of a few more or less idle rich, who make a pretense of being mining engineers that they may enjoy the opportunities and privileges a large and experienced organization affords its members in the way of pleasant and exclusive excursions or junkets at reduced rates. Busy engineers who are doing the real work of the profession seldom have time to attend such gatherings, however delightful they may be. To take a week or two from an active life one must expect in return some compensating advantages other than social, such as renewing old and making new professional acquaintances, and learning of things that will be of real assistance in daily life. The Canadian Mining Institute in this respect seems to be eminently successful and destined to have a future worthy of the great Empire of Canada and its Anglo-Saxon nation in the making.

GEOLOGICAL SURVEY APPROPRIATIONS.

The following represents the amounts appropriated by the third session of the 61st Congress for the U. S. Geological Survey for the period ending June 30, 1912.

Mineral resources of Alaska	$100,000
Rents	37,400
Salaries office of Director	35,340
Salaries scientific assistants	29,900
Topographic surveys	350,000
Geologic surveys	300,000
Mineral resources of the United States	75,000
Chemical and physical researches	40,000
Preparation of illustrations	18,280
Books for library	2,000
Skilled laborers	20,000
Geological maps	110,000
Gauging streams	150,000
Surveying national forests	75,000
Engraving illustrations for monographs; printing and binding monographs	165,000
Daniel E. Willard	400
Total appropriation	$1,508,320

Notes on Tellurium-Bearing Gold Ores

By W. J. Sharwood

*The frequency of the association of gold and tellurium has been emphasized by Kemp in the résumé concluding his excellent bibliography and list of localities of telluride gold ores,† that "tellurium is more widely distributed and more common associate of gold than has been generally appreciated." By grinding successive faces on a specimen of ore, examining them with a lens, and picking out minute particles of individual minerals for direct qualitative tests, or by selecting single grains from concentrated material, I have detected tellurium in a majority of such ores examined as have contained visible free gold.‡

The conditions under which these elements occur together admit of a division into several well-marked groups.

Classification of Tellurium-Gold Occurrences.—1. Gold tellurides proper (which may also contain silver and sometimes other elements). 1*a*. Product of partial alteration of these gold tellurides, yielding free gold on the surfaces or in cracks. Both of these modes of occurrence are well illustrated in specimens from Kalgoorlie and Cripple Creek (see Riekard, *Trans.* A. I. M. E., XXX, 708, and XXXIII, 567), and in some from California.

2. Tellurium minerals having free gold deposited on their surfaces, presumably precipitated by reaction with gold solutions. The surface of the original mineral may or may not show signs of oxidation. This condition is observable in specimens of tellurides containing lead or bismuth (usually somewhat altered) from certain veins or spurs of the Mother Lode of California, and in scattered instances in Montana.

3. Free gold associated with tellurium minerals, apparently deposited either contemporaneously or alternately. This condition has been noted in some specimens of crystallized gold intergrown with altaite from the 'pocket belt' of Sonora (Tuolumne county, California), and in the coarse free gold with bismuth sulpho-telluride of the Cable mine, Montana. To this class also belong the deposits of Goldfield, Nevada, where free gold (some of it almost absolutely pure) is associated with a complex antimonial sulpho-salt of copper containing bismuth and tellurium, named goldfieldite by Ransome. An occurrence of wire gold at Carson Hill (Calaveras county, California), mentioned by Ransome in an earlier publication, and an instance from Western Australia (Kemp, *loc. cit.*, p. 319) afford other examples.

4. Free gold associated with tellurium minerals, generally not in contact, and bearing no evidence of either having influenced the deposition of the other.

*Abstract from *Economic Geology*, Vol. VI, No. 1, February 1911.

†*Mineral Industry*, VI, 295-320. 1897.

‡*Mining and Scientific Press*, January 26 and June 8, 1907, CXIV, 117 and 731.

As instances of this class may be cited several ore samples obtained from 'true fissure' quartz veins of California, ranging from Siskiyou southward to Tuolumne county; some specimens from Mother Lode mines may also be referred to it. In most cases a lens or microscope is necessary to recognize the scattered grains or scales of the tellurium minerals.

5. Ores containing small amounts (rarely exceeding two or three-hundredths of a per cent) of gold and tellurium associated with sulphides (especially of iron and copper), and which can only be recognized after concentration by analytical or metallurgical processes. The copper ores of Australia, Arizona, and Montana represent this type, and some of the 'Potsdam' ores of the Black Hills.

6. Free gold associated with tellurium oxide, tellurites, or tellurates. These may result from oxidation of tellurides in either of the other classes. The gold may be non-amalgamable and sometimes is finely divided; the surface is sometimes distinctly 'rusty' or may be coated with an almost imperceptible film of foreign matter.

Location	Ag Per Cent.	Au Per Cent.	Te Per Cent.	Se Per Cent.	Bi Per Cent.
1. Ore, Wallaroo Mine, South Australia	0.0023	0.0002	0.001	...	0.0012
2. Average of six ores with free gold, Goldfield, Nevada	0.26	1.34	2.13	?	1.12
3. Matte, Copper Queen, Arizona	0.02	0.0035	0.0088	0.0113	0.0044
4. Matte, Butte, Montana	0.05	0.0003	0.001 to 0.01	0.001 to 0.01	0.03 to 0.05
5. Anode mud, Great Cobar, New South Wales	15.725	1.450	0.654		0.707
6. Anode mud, Butte, Montana	25	0.05 to 1	2 to 3		2 to 3
7. Typical anode mud	40	2	5		...

7. Occurrences of tellurium in detrital deposits with gold. These are, as mentioned by Lenher, so rare as scarcely to deserve recognition in a scheme of classification; they are, however, not entirely unknown. One of the earliest recorded finds of tellurium in Montana is quoted by Kemp as having consisted of scales occurring in a placer. I once found a particle of a gray crystallized tellurium mineral in a small open cavity in a grain of placer gold from Butte creek, Butte county, California, where it had been protected from wear by the gold.

While the presence of tellurium in veins has in some districts been adduced without reason to indicate their persistence in depth, its association in others with deposits of a pockety or irregular character has led to the opposite view. That it is not incompatible with persistence in depth is evident from a consideration of its occurrence in the ores of the California Mother Lode, and of the great depth attained by some mines on that lode. In the Morro Velho of Minas Geraes, Brazil, the ore-shoot is of remarkably uniform gold content and has been followed to a depth of over a mile, measured on the dip. Though tellurium is present only in minute proportions in the copper ores of Montana, Arizona, and Australia, it often far exceeds the gold in amount, as is evident from analysis of metallurgical products, especially of the slime or 'anode mud' obtained in the electrolytic refining of the copper, from which part of the tellurium has been removed during the converting or blowing of the matte.

Copper and Gold Ores and Products Containing Tellurium.—Selenium occurs in appreciable quantities with tellurium in the Goldfield ores, its presence being evident from its deposition from sulphuric acid that has been used in parting, on the large scale, the bullion obtained from southern Nevada mines. It is also present in traces in Western Australia gold ores, as well as in the copper ores previously discussed, and (also with tellurium) at the Waihi gold mine in New Zealand. It has also been found in the Republic district of Washington and exists in considerable quantities in certain silver-gold mines of Sumatra.

In testing for tellurium in minerals by the familiar sulphuric acid method there is a possible source of error, which I believe is not mentioned in the literature on the subject. Some time ago a sample presented for examination was passed on to an assistant who soon reported that it gave a strong reaction for tellurium, which seemed improbable from its general appearance. Further tests proved it to consist largely of manganese peroxide, although a fine purple color developed when it was heated with strong sulphuric acid and then allowed to stand a few minutes. The tellurium test requires that the particles be moistened with the strongest sulphuric acid and cautiously heated nearly to the point at which white fumes rise, the colored compound forming only between rather narrow limits of temperature. Several other specimens containing manganese peroxide were found to yield a similar color when similarly treated and then cooled and exposed a short time to a moist atmosphere; the color could generally be brought out by breathing on the sample while cooling. It is probably due to the formation of permanganic acid.

While this test is an excellent one for clean particles of unoxidized tellurium minerals, it often fails in the presence of large amounts of sulphides such as pyrite, and is useless in the case of oxidized compounds unless previously reduced. G. T. Holloway has described a method of isolating tellurium from ores for testing purposes, by concentrating it with the gold and silver in a lead button obtained by the ordinary fire assay, it being possible to treat as much as 50 to 60 gm. of ore in this way. The lead button is then dissolved in nitric acid, diluted, and the tellurium precipitated by means of lead foil, the deposit thus obtained being then cleared and tested by concentrated sulphuric acid.

The first important bill introduced in Congress having for its object the creation of a Federal Department of Mines was that presented by Mr. Osborne, representative from Oregon, in 1899. The bill failed of passage, though it was not without friends, even at that time. The nearest to realization to this is the recently created Bureau of Mines.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Sinking the Lightner Shaft, Angels, California

The Editor:

Sir—Responding to your request, I give the following details regarding the work recently done at the Lightner shaft:

The shaft dimensions in the rough are approximately 8 by 17 ft. The drilling is done by four machine-men, each supplied with a 'Pacific Baby Drill,' made by D. D. Demarest & Co., of Angels Camp, that requires no chuck tender. These machines are mounted on two single-screw column bars that cross the narrow dimension of the shaft, each bar holding two drills. The total number of holes drilled on each round is 24 to 30, in rows of three each. With the first setting of each column bar, the three flat cut-holes and the two rows of back cut-holes are finished. The bars are then moved and re-set for the row of vertical wall-holes. The minimum depth of these drill-holes varies from 8 ft. 6 in. in the flat cut-holes to 6 ft. in the vertical wall-holes. Each machine man completes six holes on his shift of eight hours. At times, owing to various setbacks, the drilling requires a shift and a half. The time consumed in mucking then completes the 24 hours. Our greatest record for one round of drilling and mucking was 244 buckets of broken rock, each bucket holding about 800 lb., or a total of about 97 tons. This round advanced the shaft depth about 7½ ft., and is to be accounted for by the fact that a slip crossed the shaft in such a way that the ground broke out deep on the back holes. The drills ran well, were easily handled by one man, were economical in operation, and did what we consider remarkable work. The self-tightening chuck is a splendid feature, as it cuts out all of the lost time usually spent on tightening chuck bolts and nuts.

D. C. DEMAREST.

San Francisco, February 24.

[With reference to the question raised by 'Superintendent' in our issue of February 11, the management authorizes us to say that the labor costs quoted in our issue of February 4 are correct and cover all costs properly chargeable to the work, including a pro rata of general costs.—EDITOR.]

The Clancy Process

The Editor:

Sir—I will again have to ask the patience of your readers, as a number of statements in Mr. Clancy's reply to my letter, 'The Clancy Process,' in the February 18 issue of the *Mining and Scientific Press* demand correction. The following respecting the value and application of calcium cyanamide, or its more valuable equivalent, calcium cyanide, for use in the cyanide and ammonia cyanide treatment of ores will, I trust, enlighten the cyanide-engineering profession. What is of most value to the cyanide operator in the arguments presented both by Mr. Clancy and myself, is the cheapening of cyanide: to be had at a cost of 3 to 5c. per pound, as against sodium cyanide costing 18c. Mr. Clancy wants cheap cyanide and believes he has it in calcium cyanamide. I want cheap cyanide and I feel certain I have it in calcium cyanide. Since I first presented and patented the idea, by all the laws of common-sense, I am entitled to priority in its application in ore-treatment. I am certain that the cyanide engineer is already sufficiently overburdened by an ever-increasing number of new mechanical devices and appliances, and to be successful, must these days be pretty well versed in inorganic chemistry. He can scarcely desire to be still further drawn into the more occult domain of organic chemistry as Mr. Clancy is apparently attempting to do.

When Mr. Clancy says that "the Messrs. Frank and Caro many years ago attempted to produce cyanides by this means, but found it was not a commercial success" he is only begging the question: for the process of producing the calcium cyanamide and calcium cyanide, is a mere matter of chemical control, and not of failure on the one hand in producing calcium cyanide and success achieved on the other, in manufacturing calcium cyanamide. Calcium cyanamide, due to its fixed nitrogen being readily convertible into urea and kindred organic nitrogen products, has become of great value as a 'fixed nitrogen' fertilizer, for which it is chiefly now being manufactured; while the related product, calcium cyanide, would prove poisonous in the soil to plant life, and therefore inapplicable. Even cyanamide works havoc in many instances and must be used with care. For gold and silver extraction work, calcium cyanamide has only half the cyanogen value of that of calcium cyanide, and in the commercial cyanamide, the percentage of cyanogen is so low that its use in cyanidation, even at 3c. per pound, is hardly advisable, as I will also prove. The theoretical percentage of nitrogen in calcium cyanamide, (NCa)CN, is 34.22%, while the theoretical percentage of nitrogen in calcium cyanide is 31.5%, the formula being $Ca(CN)_2$. The atomic weights entering into their respective compounds taken from the latest figures are as follows:

	Atomic weights.
Calcium	40.09
Carbon	12.00
Nitrogen	14.01

In calcium cyanamide there is one atom of uncombined nitrogen and one molecule of cyanogen. The free atom of nitrogen uncombined with carbon present in calcium cyanamide, forms, on slaking the product in water, NH_2, or amide, of no known value as a gold and silver solvent. But if this nitrogen atom be united with carbon (which is readily feasible), another molecule of cyanogen is gained or, plainly speaking, real calcium cyanamide is only of half the value, in gold and silver extraction, of c.p. calcium cyanide, due to double the quantity of cyanogen (CN) existing in the latter.

The cyanogen percentage in the various salts that are at present of interest to the cyanide engineer is given below.

	Cyanogen, per cent.
Sodium cyanide, NaCN	53.07
Potassium cyanide, KCN	39.94
Calcium cyanide, $Ca(CN)_2$	56.47
Barium cyanide, $Ba(CN)_2$	28.00
Calcium cyanamide, (NCa)CN	32.06
Sodium sulpho-cyanide, NaCNS	32.07

A typical analysis of the commercial calcium cyanamide is as follows:

	Per cent.
$CaCN_2$	57.0
Carbon	14.0
Lime	21.0
SiO_2	2.5
Fe_2O_3	4.0
Sulphur, phosphorus, and calcium carbonate	1.5
Total	100.0

Multiplying 34.22% nitrogen present in the real product by 57% the amount of c.p. cyanamide existing in the commercial salt, a percentage of 19.5% nitrogen is obtained. Since only half of this is present as cyanogen, of value in gold and silver extraction, and is equivalent to 9.75% nitrogen, and since this corresponds to 19% cyanogen, it will be seen that even at 3c. per pound calcium cyanamide is by no means a cheap cyanogen product. On an average of a 15% basis of cyanogen contents, calcium cyanamide in comparison with sodium cyanide works out as follows: 1 lb. NaCN 48 to 52% cyanogen is equivalent to 3⅓ lb. (NCa)CN of 15% cyanogen. At 3c. per pound, 3⅓ lb. (NCa)CN cost 10c., additional freight on 2⅓ lb. probably 2c., total 12c. per pound, as against 19c. for NaCN. With this comparison and the possibility of cheaper sodium cyanide, cyanamide offers for the cyanide operator not much inducement, when the impurities in the calcium cyanamide are taken into account. It is different with calcium cyanide, of a nitrogen content of 19.5%, equivalent to 36.6% cyanogen, and produced at a cost of 4c. per pound. This would make it equivalent to sodium cyanide at 6c., or one-third the present price; at that figure it will certainly prove of value on account of its cheapness, and in ammonia cyanidation of the greatest value due to the fact that in boiling off the ammonia the cyanogen goes along and is practically recovered without loss for continued re-use; or is transformed into ammonia (NH_3) and thus replenishes the ammonia losses in the mill. Calcium cyanamide when dissolved in water forms cyanamide and a host of organic nitrogen products. But returning to first principles and for easy explanation, I will reverse the appellation of cyanamide and call it amide cyanide NH_2CN. This is produced from calcium cyanamide according to an equation which may be written as below:

$$CaCN_2 + 2H_2O = Ca(OH)_2 + NH_2CN$$

To the cyanide operator amide cyanide will easily compare with ammonium cyanide, NH_4CN, a powerful silver and gold solvent. Instead of calcium cyanamide I will call it calcium-nitrogen cyanide; it will be seen at once that the nitrogen in calcium cyanamide uncombined with carbon forms amide or amidogen and cannot dissolve gold; it may perhaps silver. The real value of the product is therefore in its cyanogen content, as previously explained. Unless Mr. Clancy has found some special effect in the use of cyanamide in his researches, I can only see a slight commercial value in its adoption in cyanide treatment.

Mr. Clancy claims that he uses cyanamide *per se*. I can not see of what value this can be, even when subjected to electrolysis. It is true that Mr. Clancy protects his cyanide solution through redneing the cyanate by means of the NH_2 gronp present in cyanamide. The addition of the NH_2 to cyanate and subjecting it to the electric current, by which Mr. Clancy effects its oxidation, forms water and nitrogen, and the cyanate is thus reduced. But, after all, cyanamide is an expensive cyanide product even in its apparent cheapness, and, furthermore, lacks simplicity in its application.

Mr. Clancy forces the suggestion upon me of aiming to manufacture calcium cyanide rather than employ it for cyanide treatment. To this I will reply that I am not directly interested in a process for making calcium cyanide, as that is a matter for manufacturing chemists, but only in applying the product to the treatment of ores.

Mr. Claney, in his letter, says that I proposed to use an electric furnace product, which contains calcium cyanide of about 80% cyanogen content, prepared by secondary electric furnace treatment of cyanamide. This is contrary to the facts. In the *Electrochemical and Metallurgical Industry*, July 1909, in an abstract, the following is stated regarding the manufacture of calcium cyanamide, and it will be apparent to anyone that it is an electric-furnace process, pure and simple. "The furnaces have hence to be heated; but if the heat were applied from outside, the temperature would rise too high on the walls and decompose the formed cyanamide. The heating is, therefore, effected in the mass itself in heat-insulated furnaces by means of electrically heated rods of carbon; after a while the heating can be interrupted and will proceed automatically, all the more readily the purer the carbide."

In conclusion, I will say that I am the last one who would attempt to discourage or disparage Mr. Claney; for he certainly has done a great deal of research work in cyano-metallurgy, and by all means is entitled to the support of the cyaniding fraternity. But, at times, Mr. Clancy forgets to give credit to others who are also working on similar lines, and in his proposal to apply ferric oxide electrodes for use in cyanide treatment does not even mention the original inventor or patentee of these iron oxide electrodes, H. Speckter, U. S. patent No. 931,513, August 17, 1909. The patent is assigned to the Griesheim Electrode Co., of Griesheim, Germany. These electrodes are intended for use in the electrolysis of salt for the production of chlorine and caustic soda.

D. Mosher.

San Francisco, March 14.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Prospectors should test every kind of rock without prejudice. Often most unpromising rock proves, upon investigation, to be valuable.

Flint, such as is often seen as nodular masses in limestone, is sometimes gold bearing, and jasper is not uncommonly rich in gold and silver.

Alamo gold district is in Lower California, about 75 miles southeast of Ensenada. The first discoveries were made in the gravel by panning. The gold-quartz veins were found later.

The black diamonds, or carbons, used in diamond-drilling, are worth almost as much as the fine brilliant diamonds, the present price being $80 to $90 per carat, according to quality.

The exhaust from a steam-engine which is so loud as to be annoying, is probably due to the exhaust-pipe being too small. A larger pipe will usually give satisfactory results in the way of relief.

White Pine, Nevada, was typically a silver camp, scarcely any gold being found in the ores of the district. The richest mines were the Hidden Treasure and the Eberhardt, both on Treasure Hill. A little mining is still being done in the old district.

In order to ascertain what type of condensing plant to employ, it is necessary to compare the fixed charges with the operating expenses. The former have a relative greater importance compared with the latter when the load-factor is low, and vice versa.

In blasting, the primer should be placed near the top of the charge, and not well down toward the bottom of it. If placed too deep, there is always likelihood of the burning fuse setting fire to the powder, thereby losing the hole and causing the powder to burn, filling the workings with deadly fumes.

Potash salts of many kinds are imported into the United States from Germany, where a score or more of mines are in operation. These salts are used for many and diverse purposes—in gold mining, glass making, soap making, bleaching, dyeing, photography, medicine, in making explosives, in fertilizing, and in many other ways.

Geological age of rocks bears small relation to the value of the ore deposits which occur in them. Valuable mines are known alike in the oldest formations and in the latest Tertiary rocks, as well as in those of all the ages between them. Also, paying mines are found in rocks of almost every description regardless of their geological age.

Clay in placer mines will rob the sluices of gold if it comes in contact with it. For this reason the clay should be well puddled before it is allowed to run through the sluices. Clay is also likely to give trouble in prospecting by panning. It must either be laid aside or dissolved by rubbing between the hands in water before proceeding with panning operations.

Water-jacketed furnaces must have a constant and sufficient quantity of cold water supplied to the jackets to prevent injury to the plates comprising the furnace. Some years ago at Oro Grande, California, water being scarce, the superintendent of a small smelter at that place tried the experiment of filling the jacket of the furnace intermittently, with the result that the furnace jacket exploded during one of the periods of low water.

In concentration, to secure the best results on machines, it is important that the feed be regular and sufficient in quantity to give the machine a suitable load. The clear water must be added in proper amount and must not be allowed to vary in volume. To insure a constant and regular feed of pulp it is necessary that the water-supply reach the mortar or other crushing device in unvarying amount, and to do this the water should come from a tank in which the head is not permitted to vary, being controlled by means of a valve operated by a float.

Fluorspar was mined in the United States in 1909, according to a report just published by the United States Geological Survey, to the amount of 46,198 short tons. At the close of 1908 there remained unsold 16,864 tons of fluorspar, so that the sales in 1909, which amounted to 50,742 short tons valued at $291,747, were supplied partly from stock on hand. These figures show an increase of 11,947 tons in quantity and of $65,749 in value over the sales of 1908, which were 38,795 short tons, valued at $225,998, and are about 2½% higher than those for 1907, the next preceding normal year of business.

Wulfenite is lead molybdate. It is a common mineral in the Great Basin region, in southern California, Arizona, and throughout the Southwest. It is yellow in color, and in the pan is mistaken for gold more frequently, perhaps, than any other mineral. It is easily fusible, and dissolves readily in hydrochloric acid. If it be boiled in this acid to dryness and the residue moistened with water, upon the addition of zinc it assumes a deep blue color. Wulfenite is rarely utilized as an ore of molybdenum.

In hydraulic mines having high banks it is extremely dangerous as well as less economical to carry the face, or cut, in the form of a horseshoe. When this is done the giant soon becomes surrounded on both sides and in front by a high bank of gravel, and great falls of earth and landslides are likely to occur at any moment, overwhelming men as well as the giants and pipes leading to them. Carry the bank in as nearly a straight line as possible, or, even better, cutting to the sides so that there is a projection opposite each giant rather than a recess. Side-cutting excavates a larger amount of gravel for the quantity of water used than when the stream is directed straight at the bank.

Special Correspondence

BOSTON, MASSACHUSETTS

Comment on the Ely Central Affairs.—Report of the Ahmeek. — February Output of the First National.

Last November J. H. McMurray, of Ely, made application to be appointed receiver for the Ely Central Copper Co. At the same time an effort was made to have A. B. Witcher, of the Ely National Bank, appointed, but owing to the close relations between Witcher and C. B. Lakenan, manager for the Nevada Consolidated, his appointment was successfully opposed by the attorneys for the Ely Central, and Ed Millard of Ely was appointed, whose bond of $80,000 was indorsed by Witcher's bank, the Ely National. Chandler & Quayle, attorneys for the Nevada Consolidated, were named as attorneys for the receiver, but they were removed from that position at the request of the attorneys for the Ely Central. When an attempt had been made previously to sell certain surface rights of the Ely Central to the Nevada Con., the officials of the latter stated that their company needed no further surface rights or rights-of-way, and the sale was not made. Soon after this, it is claimed, and after H. Ellerton Lodge of Boston had undertaken the reorganization of the Ely Central, a letter was received in the East stating that Mr. Witcher and Mr. Lakenan had carefully gone over the Ely Central property with maps and surveyors, and following this a telegram was received stating that the receiver had filed with the court a petition for an order to sell to the Nevada Consolidated about 60 acres of surface rights of Ely Central ground, with certain additional rights-of-way. This was looked upon by Ely Central stockholders as an attempt to obtain valuable property rights for a pittance. The receiver, in his petition for an order to sell, stated that a minimum valuation of the Ely Central property was about $500,000. The court denied the petition on the grounds that, as an attempt was being made to reorganize the company, the rights of the stockholders should not be jeopardized by a sale at that time.

In the last annual report of the Nevada Con., Pope Yeatman, consulting engineer, asserted that the company does not require any further rights-of-way, nor additional dumping ground; nevertheless, the company became a party to the proposal above mentioned, and had the court granted the petition, the value of Ely Central holdings would have materially decreased, and the Nevada Con. would have secured the much-sought right-of-way through the Juniper claim, so necessary in enabling it to mine the deeper-lying ores in the steam-shovel pit. Further, the additional dumping ground is needed by the Nevada Con., owing to the limited space now available for that purpose. The reorganization committee becomes trustee for the stockholders, and the whole plan is being carried out for the benefit of the stockholders. The Federal Trust Co. of Boston is acting as depository and treasurer.

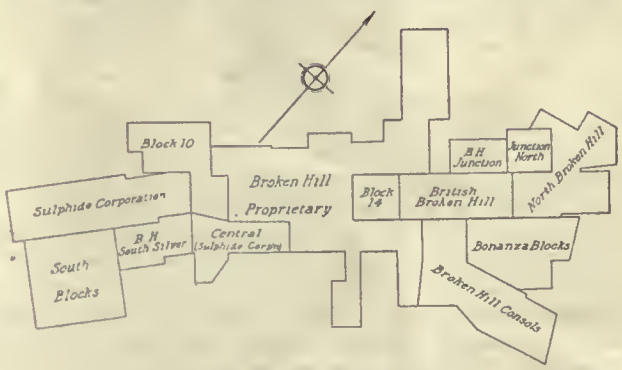
The annual report of the Ahmeek M. Co. for 1910, the second issued under Calumet & Hecla management, shows gross profits for the year of $646,520, a construction expense of $219,405, and an expenditure of $184,725 for the equipping and sinking shafts No. 3 and 4, leaving a net profit of $229,320. In this connection attention is called to a net loss of $198,996 in 1909, and $22,355 in 1908. The cost of producing copper in 1910 was 11.05c. per pound, as against 15.48c. in 1909, and 12.66c. in 1908. The cost, including taxes, of mining, transporting, and stamping a ton of ore in 1910 was $1.42; it was $1.72 in 1909, and $1.78 in 1908. The cost per pound of copper at the mine, not including construction, was 6.37c. The cost, including construction, equipment, and interest paid, was 7.53c., as against 8.71c. in 1909. The cost of smelting, freight, commission, Eastern office expenses, was 1.16c. per pound. The copper content of the ore mined in 1910 was 22.3 lb. per ton, as against 22.7 lb. in 1909. The ore broken during 1910 aggregated 568,935 tons, of which there was rejected 38,570 tons, or 6.8%. The output of refined copper for 1910 was 11,884,954 lb., or 28% increase over that of 1909.

The First National Copper Co., operating its mine and smelter at Coram, Cal., produced in the month of February 676,705 lb. copper, 28,373 oz. silver, 526 oz. gold, which was a slightly lower production than that of January. The Cottrell system for collecting the furnace fume is working satisfactorily, though the Farmers' Association seems still dissatisfied. Development with diamond-drills is in progress, with the result that the tonnage of available ore is being increased.

LONDON

Minerals Separation and T. J. Hoover.—Zinc Corporation and Elmore Process.—R. Gilman Brown Re-Opens Tin Mine.—Korean Gold.

In my letter published in your issue of February 11 I mentioned that another unfortunate lawsuit had been commenced in connection with flotation processes, the suit consisting of an action brought by Minerals Separation, Ltd., against Theodore J. Hoover, the retiring engineer for the firm. I did an unwitting injustice to Mr. Hoover by mentioning this suit, for it consisted of an *ex parte* statement in court made in the absence and without the knowledge of Mr. Hoover. In the English courts it is the custom not to report *ex parte* proceedings. In this case somebody distributed to the press a short summary of the proceedings. The fact that the papers received the information in this way is indicated by the identical phraseology of all the reports published. What actually happened was this: Mr. Hoover terminated his engagement with Minerals Separation Ltd. on December 31, after having spent three or four years improving the flotation process, and he proceeded to Russia on petroleum business. The directors of Minerals Separation Ltd. objected to his having taken away records of information in connection with the process, that they claimed were their property and not his. This application was made while he was in Russia, and he knew nothing of it for some time. On his return he soon showed that "what was his was his own", and the action was withdrawn. The offending paragraph mentioned above may have led some people to believe that some sort of unprofessional conduct was attributed to Mr. Hoover. It did not strike me personally in this way; on the contrary, I imagined that it was a dispute between employer and employed, the former claiming that the latter should forget or unlearn everything he had done during his years of service. I was expecting it to lead to a pitched battle which would settle this much vexed question. While writing of matters in connection with Minerals Separation Ltd., I may as well tell something about the fight between this company and the Zinc Corporation. It will be remembered that the latter company was formed to treat dumps of zinc tailing at Broken Hill, five years ago, and that after trying the Potter process it adopted that of the Minerals Separation. This did not work either; for it was in those days quite a crude affair. It was rejected, and the Elmore plant installed instead. This has been highly successful, as I have several times recorded already. Things went swimmingly for some time



Claim Map at Broken Hill.

until Minerals Separation Ltd. brought the original contract to the notice of the directors of the Zinc Corporation, pointing out to them the alarming provision that the Corporation should never use any other flotation process than that of Minerals Separation. Rather than risk a lawsuit, the directors of the Corporation have thought fit to gradually change the plant once more, and for the last three of four months they have been slowly substituting new Minerals Separation plant for the Elmore plant which has done so much good work. The reason for this change is ostensibly that the tailing now treated is more amenable to the new plant. This may be so or not, but it should be definitely stated that the change is being made, not on account of superiority of plant or on account of disputes in connection with patent rights, but solely because of that remarkable clause in the agreement. It is probable that it will be quite six months before the whole of the plant has been altered. It is of course not quite fair to compare the working of a new plant with one that is well established or 'tuned up'; but, for all that, I cannot help recording that the monthly profits have dropped in a rather unpleasant way since the alterations began. Further trouble is now in store for the Zinc Corporation, for the Elmore companies have commenced an action in Australia demanding a continuance of the payment of royalty on the whole output. They claim that the Minerals Separation process infringes their patents, and as this matter has not yet been settled in the Australian courts, this action against the Zinc Corporation is just one more addition to the group of actions.

The work done under the direction of R. Gilman Brown at one of the old tin mines in Cornwall has been watched with considerable interest. The various methods of reopening old mines always form a useful study. The mine in question is the Geevor and it is situated on the west Cornish coast immediately adjoining the Levant and Botallack mines. The company formed to undertake the work was floated in 1906 by the West Australian Goldfields, and it is now being reorganized by the West Australian Goldfields Assets Co. Oliver Wethered, of London, is chairman. He is also vice-chairman of the Dolcoath. A feature in favor of the enterprise is that the lodes have not been worked by previous owners to any great depth. Much development has been done during the last three years, and recently a new shaft was started. The sinking of this shaft is being conducted concurrently from two points, one part from the surface and the other from the deep adit. The surface plant consists of two Holman air-cushion stamps, Wilfleys, and vanners; plant for treating slime is to be erected. Altogether £24,000 has been spent. The company is being reorganized with a capital of £50,000 in 10s. shares, of which 64,500 will be allotted to the shareholders in the old company, and 34,893 shares are now being offered for subscription; 20,893 have been underwritten.

Some interesting work is being done in Korea by the Collbran-Bostwick Development Co., a company organized under American law, but practically directed from London. Some time ago I gave details of the Suan gold mine that it has re-opened. Information is now available relating to its work at the Ko Djin Dong copper mine. This mine was worked by the Koreans above adit. The deposit consists of lenses of copper sulphide in crystalline limestone, which also contains some sulphides disseminated through it. In order to develop the deposit at depth, A. R. Weigall, the manager, has sunk a vertical shaft, the top of which is 127 ft. above adit. At a depth of 191 ft. this shaft reached the hanging wall. As far as has been proved the deposit contains large amounts of copper ore. The ore in the lenses and in the limestone consists of chalcopyrite, arsenopyrite, and pyrrhotite, and no secondary minerals, such as native copper, bornite, or chalcocite, are found. For this reason it is considered that the ore is primary, and that therefore there is a good chance of the grade continuing in depth. The average copper content of the sulphides in the lenses is 18%, and of the limestone ore 5 per cent.

FAIRBANKS, ALASKA

Mill Tests Show High Returns. — Preparations for Placer Mining. — New Pay Channels.—Recovering Stream Tin.

In the last thirty days several mill-runs have been made at the local test-mill. The best ore was shipped from the Golden-Sherrard lease at the head of Cleary creek. One of every ten sacks was laid aside for the test, these aggregating 1½ tons, from which 9 oz. of bullion, worth $17.36 per oz., was extracted; this was equivalent to $100 per ton recovered by amalgamation. The tailing contained $13.14, while the concentrate was worth $928 per ton. The vein on this lease is 2 ft. wide. A shipment of 100 tons has been made to the Chena custom mill. The shaft is 100 ft. deep, and driving is in progress to develop the ore-shoot. Another run of 6 tons of ore was that received from Gels & Thompson, on Fairbanks creek. The recovery was 31 oz. of gold, worth $16.67 per oz., making an average of $86 per ton in free gold. Tailing contained $3.65, mostly in silver, and the concentrate assayed $130 per ton. At the 110-ft. level, 3 ft. of lead-carbonate ore occurs next to the 2 ft. of free-milling ore. The lead ore assays high in silver. The owners probably will erect a small mill this summer, thereby saving $25 per ton in transportation and milling charges. While prospecting the Pioneer Quartz Co.'s property on Chatham creek, Mr. Calvin has succeeded in finding the old vein first worked by the former company. The vein has a width of 16 in., a part of which contains high-grade ore. A shipment of 6800 lb. of this ore was made to the Fairbanks mill, the net recovery from which was 18 oz. gold, worth $17.28 per oz.; the concentrate obtained assayed $157 per ton. This was the first mine to be operated in the district, but work was stopped by an excess of water at the 100-ft. level. Work is progressing at the Peterson lease, on the Friedrich property, at the head of Vault. After reaching a depth of 130 ft., driving both east and west was started, and good ore was found in both directions, that on the west side assaying as high as $150 per ton. It is probable that a mill may be erected on this property. The Fairbanks Quartz Development Co. is raising funds to start work when the sealed proposals of mine-owners are opened. Ten proposals on favorable terms are already in. The trustees of the Fairbanks test-mill rendered their report for the six months ended January 1, 1911, which showed a total of 158 tons of ore milled, that returned bullion of the value of $15,000, or an average of close to $100 per ton. Of this ore, 48 tons was milled free of charge, while for the rest a charge of $15 per ton was made. Since February 1, only one ton from each property is being milled free of charge. The assets of mill and equipment amount to $4873, with no liabilities.

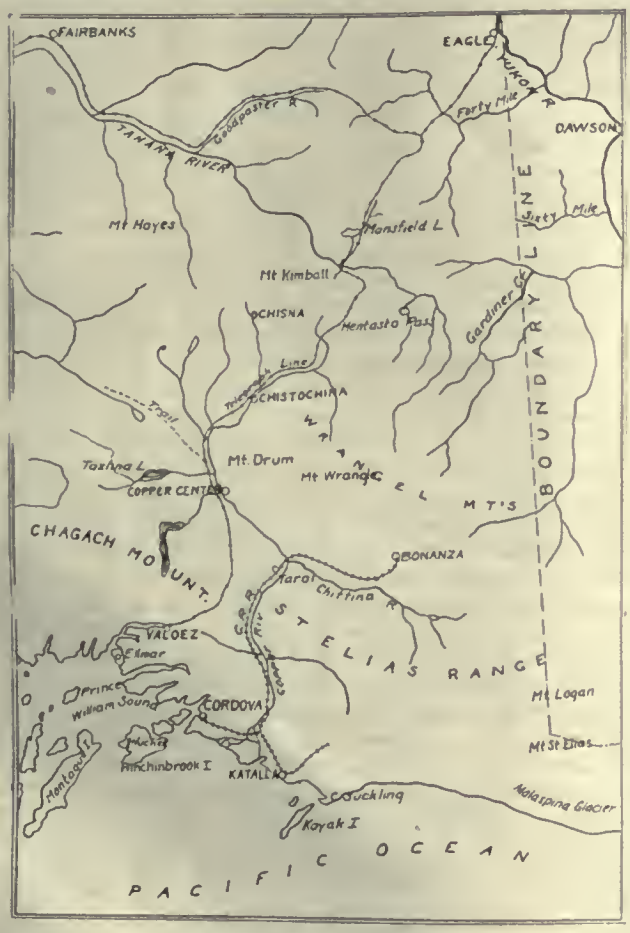
The placer miners are locating lost pay-streaks, and general success is reported. Lushbaugh and Sandstrom have just reached bedrock in their working-shaft, opening the extension on the pay-channel worked by Walter Fisher on the Niggerhead association ground at the mouth of Dome creek. The material in the shaft prospected $4.50 per square foot of bedrock. Other prospect-holes put down by Fisher show that the paystreak is at least 400 ft. wide at this point. Jerry Paulson, who has the lay below, is installing a big plant and starting a working shaft. The pay-gravel found on the benches opposite 7 and 8 Below Goldstream still holds out, and considerable money will be taken out by laymen this season. The ground owned by Bigelow and Berry is about blocked out for summer work. Reid & Co., who have a lay on 7 Below Goldstream, are in good pay. A picked wheelbarrow-load of dirt yielded $125, while $5 per pan is common. Another missing paystreak has been found on Fairbanks creek, in the left-limit benches opposite 4 and 5 Above Discovery. Holes put down by Peterson and Smallwood on one claim, and Noeller and Gustafson on the other, show the pay to extend through these two claims. The ground is 30 ft. deep, and samples show a value of $4 per square foot. Joe Eglar, of Hot Springs, recently shipped 3000 lb. of stream tin to the Tanana assay office, in Fairbanks, to be cleaned

for gold and sampled for the tin content. While over $200 in gold was recovered from the sand, a sample of the whole lot showed 60% metallic tin. Much interest is being shown in seeking the source of the placer tin, and many prospectors will be on the ground next summer. Much of the tin ore occurs in large pieces, encouraging the belief that commercial ore will be found at the source. It is thought that the placers are rich enough in tin to warrant dredging.

SEATTLE, WASHINGTON

Mining in the Cascades.—The Tacoma Smelter.— Interest in Valdez, Seward, and Iditarod.—Coal Situation.—Native Copper in Olympic Mountains.

Mining in western Washington has been quiet during the winter, due principally to heavy snow in the Cascade range; only a few mines have operated through the winter. The owners of properties in the lead district around Cascade pass are again encouraged this year by promise of the railroad being extended to tap the district. This



Southern and Central Alaska.

camp will be a large producer of lead and silver if transportation is ever obtained, but at present the nearest railroad is 60 miles distant. There have been persistent rumors of the old Monte Cristo mines being taken over by strong operators, but so far they remain idle. The Everett smelter, built principally to handle the ores of Monte Cristo, has been dismantled, and the débris is being cleaned up and shipped to the Tacoma smelter. In the Miller river district the Apex mine continues to ship a good grade of ore, and the Seattle Cascade company built a concentrating plant on its property last season. The Tacoma Smelting Co. has made a number of changes, and evidently anticipates a good year's business. The electrolytic refinery has again been put in operation, and this company is now shipping electrolytic copper.

The Valdez and Seward camps in Alaska have attracted much interest in Seattle this winter, and the idea seems to prevail that there will be a stampede in that direction this spring. A number of mills have been shipped from here this winter, and these will be erected as soon as weather conditions permit. There has been a lively sale of these stocks on the Seattle Exchange, and everything seems to point to a busy season for the two camps. In the placer field, the Iditarod country is attracting its share of the attention. A deposit of graphite is being opened near Nome, and a mill is being erected at Everett, Washington, to refine the output. Foundry facing, lubricant, and paint will be the principal products.

The coal situation is reported dull, the large production of California oil causing a stagnation in the market. However, it is not thought that the California wells will gush forever, and the Washington coal will come into its own again some day. Seattle is much interested in President Taft's recently declared intention of effecting a settlement of the Alaska coal lands controversy, and Alaskans who have been alternately in hope and despair for the last decade, again see a glimmer of light ahead. This matter is one of great interest to the whole West, which should unite in demanding a speedy settlement of the question. The cruiser *Maryland* has been making steaming tests of Washington coal, in comparison with Eastern steam coals. There has been some agitation lately to compel the Navy Department to make use of Western coal on the Pacific. The result of the test has not been announced as yet.

Reports are continually heard of the native copper in the Olympic peninsula, this State, and it seems to be well established that a native-copper district exists there, but not enough work has been done to demonstrate its value. The Olympic mountains are perhaps the least-known region in the United States today, and this fact is all the more remarkable when their nearness to the large cities of the Sound country is considered. They are inaccessible, due to the lack of roads, or even trails, the dense covering of brush and timber, and their steep slopes. Rich samples of native copper have been brought out from time to time, and the district would seem to be one well worth prospecting.

TORONTO, CANADA

Activity in Porcupine Stocks. — Electric Power Being Provided. — Development News.—Cobalt Lake.

The past week has witnessed a very decided revival of stock-market activity, the extent of the transactions in Porcupine shares recalling the earlier days of the Cobalt boom. The entrance into the field of the Bewick-Moreing syndicate, which, in addition to undertaking to develop some 50 claims, has purchased a block of Hollinger stock, gave a sudden impetus to speculation. Hollinger rapidly advanced and several other stocks in which there had been little trading previously also took a spurt hardly warranted by any evidence of intrinsic value. The market was, however, quickly steadied by the usual rush of profit-takers, indicating the purely speculative character of the movement. The Cobalts suffered considerably, many holders selling for what they could get in order to invest in Porcupine. At present it looks as though the prestige of the Hollinger and one or two other concerns on a fairly substantial basis may be the means of foisting the usual proportion of worthless or doubtful propositions on the public. Porcupine is promised electric power by about June 1. A power-plant is being installed at Sandy Falls on the Metagami river, and 70 miles of transmission wires are being strung to connect it with the camp. When complete, it is proposed to develop 8000 hp. The Hollinger has already contracted for 1000 hp. At the Rea mines, operated by the Consolidated Gold Fields of South Africa, the shaft is down 103 ft. and will be driven to 230 ft. before a level is cut. The diamond-drill shows free gold at a depth of 239 ft. The Preston East Dome company is putting its machinery in place, preparatory to beginning operations. Four shafts will be put down on the Golden Rose vein, considered one of the most promising in Porcupine. There are in all 26 veins on the properties of the company in which gold has been found. Alexander Gray, of Montreal,

who has attained considerable prominence as a writer on Canadian mining topics, has purchased the McDougall claims, north of the Scottish Ontario group, for $50,000. The Bewick-Moreing syndicate is pushing work on the Pearl Lake claims, and building camps for the accommodation of a large force. H. C. Anchor, formerly of California, has been engaged to take charge of work on the Dome Extension. The Swastika, situated some miles south of Porcupine, has a 150-ft. shaft on a vein which at this depth has widened to about 12 ft. A five-stamp mill is in operation.

The Cobalt Lake company is reducing its capital from $5,000,000 to $3,500,000 by the purchase of stock. Its position has considerably improved within a year. At the Nipissing rich ore has been opened on the 170-ft. level at about 300 ft. from shaft No. 122. The vein is from 2 to 5 in. wide. The largest individual shipment of bullion so far made from Cobalt was made by the Nipissing this week, amounting to 106,430 oz. The Hudson Bay recently opened two more high-grade veins, the principal find being on the second level 300 ft. from the shaft and about 3 in. wide. The Rochester company is increasing its capitalization from $1,500,000 to $2,500,000.

NEW YORK

Amalgamated Copper Co. to Absorb the United Metals Selling Co. — Calumet & Hecla, and the Merger. — All Mexican Proposals in Abeyance.—Porcupine Interests.

Some weeks ago the contemplated absorption of the United Metals Selling Co. by the Amalgamated Copper Co. was announced, though it was expected that it would be some time before the move was made. Now, however, the National City Bank of New York City announces that it has arranged to purchase on its own behalf and that of the Guaranty Trust Co., $12,500,000 of two-year 5% notes of the Amalgamated Copper Co. The proceeds of the sale of such issue are to be used in the purchase of the stock of the United Metals Selling Co., at $246 per share. If approximately all of the stock of the United Metals Selling Co. comes in under the arrangement, the latter will be liquidated and a selling department will be organized by the Amalgamated Copper Co., which will handle its metal products. This step is one of many looking toward a closer organization in copper circles. The movement is one which has extended from the mine operator to the metal broker. In the acquisition and liquidation of the United Metals Selling Co. the Amalgamated adds much to its present strength in the smelting industry, owing to the fact that among other assets the United Metals Selling Co. owns 40,000 shares of International Smelting & Refining Co. stock, carried on the books at par and selling in the open market at $130. This item alone would require, at market price, more than $5,000,000 of the money to be received from the sale of the short-term notes. The resignation of Urban H. Broughton as general manager of the United Metals Selling Co. is expected to be followed at an early date by his relinquishment of other official duties and in all probability his departure to England. The United Metals Selling Co. has long been known as the largest metal broker in the world; it was originally organized by Adolf and Leonard Lewisohn, before the Lewisohn family became at all prominent in mining enterprises, and Adolf Lewisohn is the largest personal beneficiary in the present transaction. At the time of the formation of the Amalgamated Copper Co. a close connection was formed between the two companies, and very soon thereafter the influence of 26 Broadway became dominant in the affairs of the company.

Matters pertaining to the Calumet & Hecla merger are at a standstill at present. All of the companies, except the Isle Royale, which is organized under the laws of New Jersey, and the Gratiot, organized under the laws of Maine, have informally voted in favor of the acceptance of the terms of the merger, as at present outlined. As to the two mentioned, if there are no legal obstacles intersposed, the new Calumet & Hecla will acquire them by purchase later. The next important step will be a hearing in the Federal Court upon the temporary injunction recently secured. None of the various steps of elimination in the different copper groups is having any effect upon the copper market. The metal market is slightly better in tone, with prices ruling around 12½ cents.

The unsettled conditions in Mexico have upset mining plans in the East. The interest in Mexican mining properties and oil lands in New York has grown rapidly in the past few years. The properties at El Oro, while held largely in England, have many stockholders in New York. The purchase of the Santa Gertrudis by the Camp Bird company was a matter of almost as much interest on this side of the water as in London. The new oilfields near Tampico have interested many New York people. All of the plans for development and further investment are now in abeyance.

Porcupine is bidding for market prominence. The Northern Ontario Trust Co. has been organized with a capital of $500,000 to operate in the new goldfield. The most important deal announced during the past few days is that of F. A. Heinze, who is said to have succeeded in interesting Sir Henry M. Pellatt, Robert E. Smith, and Daniel Mann with him in the Foster property. Sir Henry is a man of many activities in Canada, while Mr. Mann is one of the firm of Mackenzie & Mann. Mr. Heinze's organization is to be known as the West Dome Mines Co. The first money that went into the project was advanced to Mr. Heinze by himself out of the funds of the Davis Daly Copper Co.; it is now said that the new financing of the concern will permit of this money being repaid into the Davis Daly treasury. Other Porcupine properties are being brought to public attention and the investment of English capital has made the impression that the claims of the new goldfield are based on something more tangible than surface showings. There is some buying of shares of the newly promoted companies.

Smelter-fume troubles are acute in nearly every smelter district in the country. The Attorney-General, Mr. Wickersham, and the representatives of the Anaconda Copper Co. have been in consultation trying to arrive at an adjustment of the suit brought by the Federal Government against the Washoe Smelting Co. Terry & Tench, the contractors, who are known the world over, wherever engineering and construction works are under way, are backing a reduction process using superheated steam, by which it is claimed all smelter fumes can be absolutely collected and all fume trouble averted. An experimental plant capable of treating small shipments of refractory ores is to be built on the Jersey meadows, and engineers will have ample opportunity to inspect the workings of the plant. The entire operation is simple and the apparatus can be put in without detriment to present plants. There are so many visionary 'reduction processes' that for the most part mining men are skeptical in their attitude toward any such claims.

DENVER, COLORADO

Proposed Legislation. — Resumption at Leadville. — Cripple Creek Drainage Tunnel and El Paso Mine.

The mines inspection bill is suffering from too much political tinkering by legislators who are unfamiliar with coal mining. This bill was framed from the recommendations of the committee appointed by the Governor to inspect the coal mines of the State. The committee did so and made a very commendable report, suggesting changes which would reduce the loss of life in this industry. Perhaps the worst change in the original bill is the omission of the clause requiring the use of permissible explosives. When it is an established fact that the flame from black powder is the most prolific cause of dust and gas explosions, it is beyond comprehension how legislators can omit this clause. The minimum quantity of air to be circulated for efficient ventilation has gone unspecified. If the 100 cu. ft. per man per minute originally specified is too much, then a smaller quantity should be definitely stated instead of leaving it all to the mine inspector and

his subordinates. The power of the Governor to appoint the mine inspectors has been limited to appointing only the chief inspector, who will select his own assistants. This unlimited power to appoint inspectors is wrong. Rigid, efficient inspection can not be expected until the inspectors are under civil service regulations. The proposed levy of one cent per ton on all coal mined, to provide revenue for the support of the inspection service, and for the establishment of miners' classes in the respective coal camps, has been reduced so that the necessary expenses of inspection only will be covered. The question as to whether this levy may not be considered double taxation and hence unconstitutional has not been raised.

The project to put a State tunnel through the continental divide, from Tolland to Arrow, is still a live topic around the Capitol. One faction counsels delay sufficient to consider the question as befits its importance. The other faction is clamorous for an appropriation of $5,000,000, and a careful consideration afterward. It is to be hoped that the legislators will take the middle course of appropriating a few thousand dollars to cover the expenses of a thorough preliminary examination. This is a matter of vital importance to Denver and should be handled as a business proposition.——Leadville is again enjoying the smile of prosperity. The recent cut of $2.50 per ton in the price of zinc ores, which caused most of the mines to shut down, was due largely to an agreement between the local ore-buyers. When they found that the mines would not operate at that price, they changed their attitude and have made several long-term contracts at practically the old figures. The Waterloo, Maid of Erin, Henrietta, Adams, Wolftone, Castle View, Iron-Silver, and Carbonate of Zinc mines have all resumed shipment.——The directors of the Roosevelt Deep Drainage Tunnel Co., of Cripple Creek, have just let a peculiar contract to the management of the El Paso Consolidated Gold Mining Co. The El Paso company is to extend the Fuller cross-cut 125 ft. to open more completely the C. K. & N. fissure. If the flow from the tunnel is increased 1000 gal. per minute, the tunnel company will pay half the cost of the work. If the flow is increased 2000 gal. per minute, the tunnel company will pay the whole cost. There is little doubt in the district about the success of the work. The bottom level of the El Paso mine is now accessible.——The Portland Gold Mining Co. is having a model of its properties constructed in its Colorado Springs offices. The model is of the conventional glass plate type. The dimensions of the enclosing frame are: width, 8 ft.; length, 16 ft.; height, 5 ft. This is one of the largest models on record.

BLACK HILLS, SOUTH DAKOTA

Re-Opening of the Golden Slipper Mine.— Wasp No. 2 Mill-Work.— Golden Reward to Erect Mill. — Building Smelter at Galena. — Maitland District.

With the opening of spring the mines of the Black Hills region are beginning to show more activity, and new work is being undertaken. One of the most interesting ventures is the re-opening of the Golden Slipper mine, near Hill City. This property had been shut down for a number of years, operations having been suspended at a time when there was a burden of debts. A number of attempts had been made to interest investors in the re-opening of the mine, but no one was found who was willing to assume the obligations. During last winter business was quiet in Hill City, and C. E. McEachron, a merchant creditor, D. W. Webster, receiver, and Dell Canfield, a mining man well acquainted with the property, secured an order from the court to enter and work the mine, with the understanding that no further indebtedness would be allowed to lie against the mine. These men secured a crew of miners who were willing to be paid from the profits of the ore milled, and the shaft was unwatered. Results of clean-ups so far have been successful, and while the vein is small, the ore is high grade, and nearly all of it free milling. Their efforts have had such a satisfactory outcome that it is expected capital will be secured for further sinking and modernizing the antiquated 5-stamp mill. The Forest City mine, Hill City district, is producing free-milling ore that yields $10 to $15 per ton. This ore is taken from a vein 5 to 7 ft. wide, at a depth of 250 ft. Further sinking is contemplated. Alfred Damy is superintendent.

The Wasp No. 2, near Lead, is operating steadily. The mill is treating an average of 400 tons of ore per day by dry-crushing and cyanidation. For the month of February the cost of mining and milling amounted to 75c. per ton. The mill was started in December, and within a month or two it is expected that dividends will be declared. A cave of an old stope on the 200-ft. level of the Rattler vein made an opening to the surface on Gold street, in Lead, undermining and taking away a corner of the Campbell House annex and a corner of a steam laundry. The Homestake company, owner of the caved stope, immediately put in a belt-conveyor and set men and teams to work hauling rock to fill the cavity. No further trouble is anticipated. The Golden Reward company has announced that a mill of 500 tons daily capacity will be erected near the site of the present plant, in Deadwood, to handle the ore from the recently opened ore-

North Homestake Mill, Maitland, South Dakota.

shoot, mention of which has been made in these columns. This will give the company a capacity of close to 800 tons per day, as the present plant is now treating about 275 tons each 24 hours. H. C. Osterman, of Chicago, who is building a smelter in the old camp of Galena, is expediting work as fast as the weather will allow. The site of the plant is 2000 ft. below the present terminus of the C. B. & Q. railroad, and the grading for an extension to the plant is completed, and the laying of rails has commenced. Grading for the smelter foundations is practically finished, and construction work is to progress rapidly. Some machinery, stacks, and structural steel were bought from the Golden Reward company, being equipment of the old D. & D. smelter, in Deadwood, and this will be moved to Galena as soon as the railroad is completed. It is estimated that it will make 25 narrow-gauge carloads. The Gilt Edge-Maid company is to erect a concentrator to treat its pyritic ore, as this company has a contract to supply Mr. Osterman with a large tonnage of concentrate. The Altia company may resume work, as the new smelter will afford a market for its concentrate. C. B. Harris, who is making ore-shipments to outside smelters from the Richmond-Sitting Bull mine, at Galena, is preparing to put in more machinery to facilitate work and increase production by the time the smelter is started.

The Echo company, Maitland district, is cutting a station at a point 600 ft. from the mouth of the cross-cut tunnel, where an electric hoist is to be set. By means of this adit a large vein of ore similar in character to that of the Homestake has been opened, and further development at depth, it is hoped, will disclose a pay-shoot. The North Homestake, at the same camp, has been kept in good condition during the two years it has been idle. The water has been kept pumped out during that time. Recently a small air-compressor was installed which will make it unnecessary to run the 600-hp. compressor when sinking

is started. A supply of shaft timbers has been delivered and framed, a new electric mine-pump put to work, the entire mill roof shingled, and a comfortable house erected for the superintendent, L. M. Maitland. It is believed that when pending litigation is settled, the first work undertaken will be to sink the shaft deeper, in order to make available ore which has been disclosed by diamond-drilling from the present bottom, 220 ft. in depth. The ore on this level is in the Cambrian quartzite and shale, but the underlying slate has been found to carry veins of Homestake type. The Reliance company, at Portland, is remodeling the mill and putting in 10 stamps. These will be given a thorough try-out, and possibly some of the troubles arising during former milling tests, when Chilean mills were used, will be overcome. The plant may be working within 30 days. The last mill operations gave a margin of profit, but a suspension was necessary in order to relieve the property of debt which encumbered it when milling was commenced. This has been accomplished by a reorganization of the corporation.

JOHANNESBURG, TRANSVAAL

Discussion of Problems in Deep Mining. — Milling Methods on Rand. — The Sheba Mine. — The Tin Mining Industry Active. — The Occurrence of Tin Deposits.

The problem of winding from great depths has long been regarded as one of the principal difficulties with deep mining on the Rand, but as the mines gradually increase in depth the prospects of solving the difficulty, now that electrical power is likely to become generally adopted, are becoming more encouraging. The question was recently mentioned in a paper read by Alpheus Williams, general manager of De Beers mine, before the South African Institute of Engineers at Kimberley, on 'Handling Large Quantities of Ground.' The author pointed out that the success at Kimberley centred in the concentration and winding of the blue ground from one point, the cost of lowering it from the upper levels and re-loading being only 0.2d. It was also mentioned incidentally that something of the same kind was contemplated at the Crown Mines, Johannesburg, where a much larger tonnage was to be hoisted in the future from two shafts than was already hoisted from ten. This idea has long been urged here by Tom Johnson, who has frequently pointed out that concentration of work is one of the features connected with the handling of large outputs of coal at low cost in England. Mr. Williams pointed out that at the Crown Mines it was contemplated to hoist between 9000 and 10,000 tons per day from two shafts, which would be a great step forward, seeing that probably on the Rand today no one shaft succeeded in hanling more than 2000 tons per day. Another question incidentally mentioned in the paper was the large amount of time necessary for lowering the persons employed underground at these mines, where the work was concentrated on few shafts and the necessity that existed therefore of doing everything possible to increase the efficiency of the underground workers so as to keep down the number to the lowest possible minimum. In this respect it was shown that owing to the introduction of tube-mills the duty had been increased at the stamp-mills in some instances four-fold, and to keep the mill going four times as many hands as before were required below ground. Clearly, the present day tendency was to increase the difficulties connected with the lowering and raising of men, which would only be overcome by increasing the number of engines set aside for handling men alone.

The Butters vacuum-filter seems to be meeting with acceptance on the Rand; for several months it has been in use at the Crown Mines, and it is now decided to introduce it at the New Modderfontein, Robinson, and other mines. In treating the accumulated slime at the Crown Mines a liberal use of lime has been found necessary, running from 20 to 35 lb. per ton, and the cost of treatment is expected to run under four pence per ton. For the New Modderfontein two 1000-ton presses have already been ordered, while the capacity of that for the Robinson mine will be 1300 tons per day. At several ore-reduction works on the Rand, notably at Randfontein Central, fixed amalgamating plates are being used in place of shaking plates. It is found necessary, however, to nearly double the inclination of the plates when stationary, 18° being quite a good grade; in fact, it is found that a better extraction is obtained by the stationary plates as compared with shaking plates. The Sheba mine, in the Barberton district, is an extensive property and is known in parts to contain some highly payable ore, but being scattered and somewhat difficult of access, is expensive to get to the mill. During the past year operations have been largely confined to the best parts of the property, with the result that the ore sent to the mill has increased from 6.17 dwt. to 8.88 dwt., with a slight addition to the working costs. The tributing of the lower-grade sections of the property has not been taken up by tributors to the anticipated extent; no discoveries can therefore be attributed to their operations; but the modified system of handling the property as carried out during the year has been to the advantage of the company. The extraction was low, only averaging about 78%. It is purposed to reduce the nominal capital of the company to something approaching the market value of the shares, at which reduced figure it is hoped the profits earned will suffice to allow the payment of dividends to be resumed.

Map of South Africa.

Owing to the higher price of tin and the important discoveries made in the north of Pretoria, the Transvaal tin industry is attracting some attention. Prior to the working of the northern tinfields in 1907, the annual production was only valued at £4474, and that was a record production obtained from the Swaziland alluvial tin deposits. The opening of the northern tinfields brought the value up to £27,184, and in 1908 to £81,677. In 1909 it was £148,336, and for the year ended June 30, it again doubled, being returned at £303,210. Since that date it has steadied somewhat, but the industry is only in its infancy, and this year there ought to be a marked improvement in the value of the output. One mine alone is already producing more tin than the celebrated Dolcoath mine, the Zaaiplaats output for last month being 160 tons of concentrate, containing 70% tin, valued at £18,000, of which £14,000 is estimated as profits. Last year the property paid 80% in dividends, and in January another 50% dividend was declared. The mode of occurrence of the tin deposits in the northern Transvaal is somewhat peculiar. Generally they occur in the shape of pipes or chimneys in the red granite of more recent geological age than the old gray granites. They occur in various shapes, often running at a low angle. In one instance, at least, they are found in the shape of lodes, such as, for instance, at Rooiberg, west of Warmbaths. The resources of these northern tinfields are somewhat difficult to estimate, but so far the Zaaiplaats mine shows no falling off in depth,

General Mining News

ALASKA

HAINES DISTRICT

The Porcupine Gold M. Co., whose well equipped placer mine is situated on Porcupine creek, 38 miles westerly from Haines, recovered gold of the value of $65,875 during part of the 1910 season, at a cost of $22,438. According to statements made by S. C. Hunter, the company's manager, the gravel that was washed yielded $5 per cubic yard. Its high-line flume, now finished, has a length of 8172 ft., and is 240 ft. higher than bedrock. In its course it passes through a 170-ft. tunnel and crosses a deep ravine over a bridge. The bedrock sluice, started in 1909, was extended

Main Flume, Porcupine Mine.

2000 ft. during 1910, the head of which is necessarily kept up to the face of the banks being hydraulicked. Additional derricks are provided for lifting the boulders. Steam hoists and trolley lifts are used in elevating the gravel from bedrock to the sluiceways in some parts of the property. The company anticipates doing a full season's work in 1911, as all equipment is complete.

JUNEAU DISTRICT

The report of the Alaska Treadwell Gold M. Co., for the month ended February 15, 1911, is as follows: The 240-stamp mill ran 29 days, 21 hr., 57 min., crushing 34,720 tons of ore, producing 630 tons of concentrate. Estimated gross value of free gold saved, $49,781; estimated gross value of concentrate, $36,237; total, $86,018. Estimated total realizable value, $81,741. Operating expenses, $78,568; net operating profit, $3172. Construction expense, $14,408. Yield per ton of ore milled, $2.47; stock of broken ore, 32,364 tons. Development work performed, 844 ft.—97 ft. in ore, 747 ft. in waste.

Report of Alaska Mexican Gold M. Co. for the month ended February 15, 1911, shows that the full mill of 120 stamps operated 30 days, 16 hr., 12 min., crushing 17,853 tons of ore, and saving 390 tons of concentrate. Estimated gross value of free gold recovered, $34,842; estimated gross value of concentrate, $38,421; total, $73,263. Deducting $483 as value of 648 tons of ore from 700 Claim mine, leaves a total production of $72,780. Estimated total realizable value, $70,147. Operating expenses, $34,105; net operating profit, $36,042. Construction expenses, $2883. Yield per ton of ore milled, $4.07. Stock of broken ore, 4814 tons. Development work, 602 ft.—290 ft. in ore, 312 ft. in waste.

THE KUSKOKWIM

It is announced that the Northern Navigation Co. is arranging to put steamships in commission to ply between Seattle and the head of navigation on the Kuskokwim. By this route it is planned also to deliver supplies to points on the Innoko, as the two streams are separated by narrow tracts of country in various places over which portage roads are established. Falcon Joslin, having large interest in the Fairbanks country, has promoted a company which is to establish wireless telegraph stations at Iditarod, on the Innoko, at Georgetown on the Kuskokwim, and at Nulato on the Yukon. Nulato is situated not far downstream from the mouth of Koyukuk; Georgetown is the principal town on the upper course of the Kuskokwim.

ARIZONA

COCHISE COUNTY

Plans have been drawn by C. H. Repath and others for the reconstruction and enlargement of the Calumet & Arizona smelter at Douglas. The plans are to be submitted to the board of directors next month. It is not expected that actual construction work will begin for some time.

GREENLEE COUNTY

The Calumet & Copper Creek M. Co., having a mine and mill at Copper Creek, has issued first-mortgage bonds, the proceeds of their sale to be used in building a mill of 1000 tons daily capacity.

MARICOPA COUNTY

The Mazatal Development Co. has 20 mining claims situated in Mazatal mountains, 67 miles northeast of Phoenix. The locations cover a mineralized zone, in which is found ore containing gold, silver, and copper, the last named being of most importance. Theodore Phillips, John Munger, and C. W. Jayred organized the company. The claims were purchased from B. V. Davis, Charles Slaukard, and E. W. Lightner.

MOHAVE COUNTY.

The Klondike Gold M. & M. Co. has been organized by J. S. Withers and L. J. Lassell, of Kingman, to develop the Klondike group in Weaver district, in Blue ridge range, west of Chloride, and near the Colorado river. The property was partly developed and a small mill was built a few years ago by Charles Gracey and Joseph Wharton. A. F. Muter and John Hall later cyanided the mill tailing. The main vein is to be opened by driving a cross-cut. The ore is said to be well adapted to cyanide treatment. The Tennessee mine, situated at Chloride, and in control of one of the subsidiary companies of the United States company, has a new shaft, which has reached a depth of 500 ft. A drift from the 500-ft. station broke into the old workings, tapping a large volume of water, which soon filled the new shaft to the 200-ft. level, where the pumps are set. Three pumps are kept in operation, and a bailing skip, capable of lifting 18,000 gal. of water per hour, is in use unwatering the mine. Sinking is to be resumed as soon as this is accomplished, and when 600-ft. depth is reached another drift will be driven to connect with the old workings at that depth. This is a lead-zinc mine, which was formerly productive.

CALIFORNIA

AMADOR COUNTY

The California Con. Mines Co. has executed a trust deed to the United States & Mexican Trust Co., and is to issue bonds of the amount of $500,000, the proceeds of their sale to be used in paying the company's indebtedness. The

company owns the Keystone mine at Amador City, and the Wildman at Sutter.

CALAVERAS COUNTY

The Easzy Bird mine and 10-stamp mill, near San Andreas, are operating. The ore being milled is of good grade, and the force in the mine has been increased. It is claimed that three defined lodes have been intersected in driving a cross-cut at the Ariel mine.

ELDORADO COUNTY

A vein of telluride ore has been opened on the Limpinsel mine. Some new machinery is being put in position at the Kum-Fa mine, at Smith flat, and connection is being made with the electric-power line. In exploring the Georgia Slide mine, near Georgetown, the present owners have discovered a vein in which rich ore was found, some samples assaying $100 to $250 per ton. This ore was found 80 ft. below the surface. A force of 16 men is employed on the Landecker mine, at Placerville, 3 machine-drills being in use. Ore for a 48-hour mill-run yielded 55 oz. gold. This property is now owned by the Hope M. Co., for which Dr. Burger is superintendent.

INYO COUNTY

The Mortimer M. Co., for which Asa B. Hall is superintendent, is developing the Union mine, out from Owenyo. A 500-ft. adit has been driven, 200 ft. of which is on a vein in which there is gold and silver ore worth about $9 per ton. A force of 18 men is employed.

KERN COUNTY

Litigation concerning the affairs of the Hamilton Gold M. Co. has ceased, and the company has been reorganized under the name of the Antelope Gold M. Co., the directors of which are A. E. Wiley, Alfred Solano, David Goldberg, and C. S. Bartholomew. Mr. Wiley is superintendent, and has a force of 25 men at work mining ore and operating a 5-stamp mill. The mine, situated at Rosedale, has been opened by a 900-ft. adit. It is thought that the capacity of the mill will be doubled. The Pine Tree mine, in Tehachapi district, is reported as having been sold recently. This property has been worked intermittently for 30 years, and has a mill equipped with stamps and concentrators. W. H. Boison and Roy Baker, mining on the Santa Ana, in Stringer camp, near Randsburg, cleaned up $1200 in gold as the result of milling 17 tons of ore. The property belongs to the Stanford Mining & Reduction Co. W. A. Wickard, having a tungsten mine near Randsburg, has accumulated a lot of ore which is to be concentrated at the Red Dog mill in Stringer camp. The ore contains gold and tungsten.

NEVADA COUNTY

It is announced by the *Grass Valley Union* that M. I. Dow of Boston, and Mrs. B. R. Shankland of Colorado Springs, have become interested with W. H. Martin and others in the Mayflower mine, situated at Canada hill, and that new equipment is to be provided, including an air-compressor and machine-drills. The compressor and other machinery are to be electrically operated, and to obtain power for this purpose a line is to be extended to the Mayflower from the Pittsburg mine where it is to connect with the Bay Counties power system. A small force of men is now employed, and operations are to be more extensive later. The Mayflower was formerly a producer.

RIVERSIDE COUNTY

Morgan & Bradley have shipped three carloads of ore from their mine in Riverside mountain district since Jan. 15. This is said to have sampled $100 per ton. The Calzona Mines Co., operating in the same district, has ordered a gasoline hoist for its property. The principal supply point is Parker, Arizona.

SAN DIEGO COUNTY

The Golden Chariot M. Co., which has been organized with George B. King, Charles T. King, J. H. Isham, R. P. Trainor, and J. W. Elder as directors, is to develop and operate a mining property at Julian.

SHASTA COUNTY

(Special Correspondence.)—The Bully Hill Copper Co. has decided to undertake the smelting of zinc at its Delamar smelter. The plant will be altered and remodeled, the cost of which is expected to approximate $75,000. In this zinc smelting the copper and gold in Bully Hill ores will also be recovered. The chief advantage claimed for the zinc process is that it will eliminate the poisonous fumes attending copper smelting, thus permitting the company to resume operations with both of its furnaces. The Bully Hill plant embraces two blast-furnaces, copper converters, and other equipment, and was completely overhauled and remodeled about four years ago. The mines are situated near the town of Delamar, the ore lying in the rhyolitic belt, on the east side of the Sacramento river. The 3-compartment shaft is over 900 ft. deep, and the properties have been developed to greater depth than any other copper mine in the county. Considerable of the ore assays high in copper, its gold and silver content being $2 to $3.50 per ton. Large quantities of zinc also occur, which in the past has caused considerable trouble in treatment. It is understood that D. M. Riordan, the manager, will arrive from New York early in April to direct operations at Delamar. It is reported that the Afterthought Copper Co., owning the Afterthought mine at Ingot, will commence the building of a 14-mile railroad from Ingot to Bella Vista

Bully Hill Smelter.

shortly. The Afterthought lies in the same ore-zone as that of the Bully Hill group, and the success of the latter with its new smelting process will have an excellent effect on future conditions at the Afterthought. The Spread Eagle group has been bonded to the Shasta Exploration Co. for $125,000. The bond runs for 18 months. A one-tenth payment has been made. The group embraces 22 claims and is situated a short distance north of Redding. The property has been opened by shafts, tunnels, and raises, approximately $65,000 having been expended in this work by the Onn family, the original owners. Representatives of the Farmers' Protective Association are making extensive tests of the smoke issuing from the Cottrell fume-controller at Coram. It is expected that a report will be made within a few days, and upon this will depend the future attitude of the farmers toward the First National Copper Company.

Redding, March 20.

SIERRA COUNTY

The Sovereign mine, in charge of F. O. Richardson, will be active this season. A new lode of pay-ore was opened last December, and this is to be thoroughly developed. Ore-bins are to be built, and if the supply of ore made available during the next four months warrants it, a mill is to be erected later in the year. John W. Deal, John Tournay, and Ben Hagen lost their lives in a snowslide while going on snowshoes from the White Bear mine to the Monte Cristo gravel mine on March 7. Other men were in the party, but they escaped the avalanche.

TRINITY COUNTY

The Trinity Gold Mining & Reduction Co., operating the mine and mill locally known as the Headlight, near Carr-

ville, spent last year $25,686 in developing the mine, and $158,449 on its mill and power-plant. The mill, consisting of eight 5-stamp batteries, amalgamating-plates, and a cyanide plant, was fully described in the *Mining and Scientific Press* of December 31, 1910. It is estimated that the ore reserves amount to 400,000 tons.

COLORADO

David H. Moffat, of Denver, Colorado, died at New York on March 18, at the age of 72 years. He went to Colorado in 1860, and from 1870 to 1890 he was active in mining operations at Leadville, where he attained great success. He held large interests in mining properties in other parts of the State, and throughout his career he was recognized as a factor in the mining industry. He was a financier, and developed mines with his own funds and those of his close associates. During the fifty years of his residence in Colorado, Mr. Moffat was influential in projecting and building railroad lines, the South Park road, extending from Denver to Leadville, via Breckenridge and Kokomo, having been built by a company that he organized. This was accomplished in the seventies, and it afforded the first outlet for Leadville ores. The building of the Florence & Cripple Creek railroad was greatly due to his energy; but the culmination of his achievements was the building of the Denver, Northwestern & Pacific road, now operating between Denver and Steamboat Springs, Colo., but destined to be extended to Salt Lake.

GILPIN COUNTY

(Special Correspondence.)—W. E. Renshaw, of Idaho Springs, has taken over the Crown Point mine. The water is receding since the vein was intersected by the Newhouse adit, and by the time the repairs are made the workings will be dry. The mine was formerly a producer of high-grade ore. J. Stephens, leasing on the 700-ft. level of the Topeka mine in Russell gulch, is stoping a body of ore that is 2 ft. wide. Returns of from $20 to $25 per ton are being realized. The water in the Phoenix-Burroughs mine has been lowered from the 300 to the 500-ft. level. Shipments of mill-dirt are to be started to the various custom plants. Seven feet of ore, exposed on the Beliman vein, assays about $30 per ton in gold and silver. Operations are through the Central adit. Water is being lifted from the Hubert shaft on Quartz hill. The shaft is down 1200 ft. and as soon as the workings are dry drifts will he started from the 1050 and 1200-ft. levels. The First National T. Co. is carrying on development, a body of low-grade ore being in evidence. Within the next two weeks connection will be made between the workings on the Gunnell vein and the Newhouse adit. At that time the scope of operations will be enlarged.

Central City, February 20.

The Frontenac mill, recently finished, is operating and treating 250 tons per day of ore being taken from the Frontenac and Adduddel mines, where 20,000 tons of milling ore is available. The cost of transporting the ore to the mill and treating it is given as $1.85 per ton. The mines are close to Central City, and the mill is at Black Hawk.

LAKE COUNTY (LEADVILLE)

A small tonnage of zinc ore is being shipped from the Colonel Sellers mine, on California gulch. The property is in control of the Empire Zinc Co., which expects to greatly increase its production in the next few weeks. A body of lead ore, 4 ft. wide, has been opened in one of the drifts on the 300-ft. level of the Helena mine, situated on Iowa gulch. The ore is said to be 40% lead. The Little Johnny mine, the greatest on Breece hill, continues to produce high-grade gold ore. The Cofield lessees, at No. 2 shaft, are especially fortunate in finding such ore. Several sacks of ore were taken from narrow streaks which contained 200 oz. gold per ton. This stuff is pulverized and melted at T. D. Kyle's assay office. This No. 2 shaft was retimbered recently, and now operations are going on with a good force. The Little Johnny belongs to the Ibex M. Co. N. Hill and associates are shipping 1000 tons of ore per month from the Baby shaft, California gulch. The ore contains lead, principally, and is of good grade. Ore-shipments to the amount of 75 tons per day have been resumed at the Garbutt mine, on Breece hill. The New Monarch Mining Co., operating the New Monarch and Cleveland mines, near Big Evans gulch, shipped during February 87 carloads of ore, and the March shipments are expected to reach 100 carloads. David Harris, who has acquired an interest in the Forest City lease, Carbonate hill, has taken charge of the work. It is probable that this shaft will be sunk deeper in order to get at the orebodies believed to exist in the lower planes.

PITKIN COUNTY

Approximately $250,000 has been expended in unwatering the Mollie Gibson and Smuggler mines, retimbering, and cleaning out the workings, and mining operations are to begin. These are among the oldest mines at Aspen, and have been great producers of lead and silver ore. The management has 250 miners on the payroll. Good ore has been found on the twelfth level, and future development is to be on and below this level. The Morning and Evening Star mines, at Tourtelotte park, near Aspen, owned by Jerome B. Wheeler, have been leased to the Chicago M. M. & D. Co., which is to re-open those properties.

SAN MIGUEL COUNTY

The shipments of ore and concentrate from Telluride during the month of February amounted to 68 carloads, as compared with 88 cars in the corresponding month of 1910. The *Journal* of that place attributes the decrease partly to the greater concentration of ores and partly to the closing of several mines due to heavy snowfall.

SUMMIT COUNTY

The Miami Mines Co. has given a bond and lease on its holdings at Kokomo to the Elk Mountain Mining & Leasing Co. of Colorado Springs. The mine has been opened by a 1670-ft. adit. In a 90-ft. drift on the vein a body of ore 2 to 6 ft. wide is being developed. This is 800 ft. below the surface, affording plenty of stoping ground. The ore contains silver, lead, and gold. T. Connors is in charge of the work, and shipments of ore are to begin soon.

According to reports from Breckenridge, dredging operations are to begin early this season. The Reliance Gold Dredging Co. will operate a dredge on French gulch; the Colorado Gold Dredging Co. may operate two Bucyrus boats on Swan and Blue rivers; and the French Gulch Gold Dredging Co. is expected to have its Reilling dredge at work in April.

TELLER COUNTY (CRIPPLE CREEK)

The El Paso Con. Gold M. Co. has re-elected its officers, who are as follows: President, A. L. Burris; vice-president, J. N. Beatty; secretary and treasurer, Daniel Thatcher; mine superintendent, John H. Nicholls. The gross production of the mine for 1910 amounted to $505,233, the larger proportion of which resulted from the output of lessees. During the year 8262 ft. of development work was performed, including the sinking of a new shaft. The company contributed $32,800 toward the expenses of driving the big drainage tunnel in 1910. The dividends for the year amounted to $49,000. At present there are 25 sets of leases in force in El Paso ground, 15 of which are productive. The company is reserving to itself the development of all ground below the 400-ft. level. The draining of the C. K. & N. water-channel into the Roosevelt tunnel has resulted in lowering the water in El Paso workings down to the 1000-ft. station, and the orebodies at that depth are to be mined.

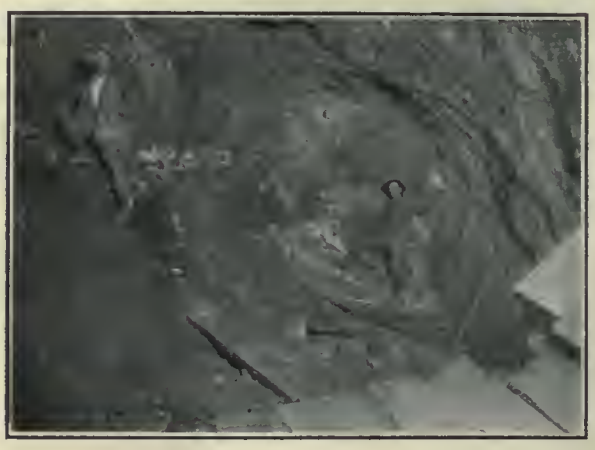
The Cresson Con. Gold M. & M. Co. is reported as producing 2500 tons of ore per month, of an average value of $18 per ton. It is estimated that the costs of mining, shipping, and treatment aggregate $10 per ton. The Elkton company is said to be mining and hoisting ore at a cost of $2 per ton, which is probably as low as any in the district. About 9000 tons of ore per month, of an average value of $3.25 per ton, is being treated in the mill

of Stratton's Independence, Ltd., and this ore was taken from the dump.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—During the last three months ore of the gross value of $30,000 per month has been shipped from the Caledonia mine at Wardner. The west drift on the 500-ft. level has been extended 200 ft., and this resulted in opening a body of mill ore, accompanied by streaks of ore containing 1200 oz. silver per ton. The raise from the 500 to the 300-ft. level is finished, and was driven in ore the entire 200 ft. The 2800-ft. adit-level is being driven with air-drills; the heading is in over 700 ft. on the vein. This is to serve as a level for ore haulage when finished, and will give a depth of 700



Taylor Stope, Caledonia Mine.

ft. below what is now the lowest level. This adit starts in Deadwood gulch, which leads into the Coeur d'Alene river below Kellogg. Eventually a concentrating-plant may be erected near the adit's portal. Regular shipments of high-grade ore have been made during the last year, and a considerable tonnage of mill ore has accumulated. The ore comprises lead-carbonate and chloride of silver in the higher workings, and galena, sulphide of silver, and tetrahedrite in the lower workings. Charles McKinnis of Wallace has charge of the property.

Kellogg, March 18.

MONTANA

DEER LODGE COUNTY

(Special Correspondence.)—It is claimed that the money necessary to build an electric railway from Anaconda to Georgetown and Cable district has been subscribed. At present there are 10 or 12 mines operating in this district, and it is predicted that six other mines will be active in the next few weeks. The present activity is greater than it has been for several years, and it is believed there would be profitable business for the projected railroad, especially in the transportation of ore. The length of the proposed line is about 20 miles.

Anaconda, March 16.

MADISON COUNTY

(Special Correspondence.)—The discovery of rich ore near Sheridan is attracting prospectors and mining men to that place. The find was made by two miners who shipped six tons of ore to the Washoe smelter from which they realized $13,250.

Sheridan, March 15.

NEVADA

LYON COUNTY

The Nevada-Douglas Copper Co. has taken steps to raise a fund of $80,000 to be expended in properly equipping the mine and getting it ready for producing a certain tonnage of ore by the time the Mason Valley smelter is completed at Wabuska. It was decided to sell 40,000 shares of the company's treasury stock at $2 per share, in order to provide the sum required. The directors and other large stockholders entered into an agreement to take the entire amount, but the other stockholders are first offered the right to subscribe *pro rata*, and are allowed until May 1 to exercise that right, but subscriptions are limited to 5% of present holdings.

NYE COUNTY

The Round Mountain M. Co. is milling about 3000 tons of ore per month, of a gross value of $30,000. The property is controlled by Loftus & Davis, and is situated at Round Mountain, 75 miles north from Tonopah.

WASHOE COUNTY

A discovery of high-grade gold ore is reported having been made on the side of Fort Sage mountain, situated in Nevada, 18 miles southeast of Amadee, a station in Lassen county, California, on the N. C. & O. railroad. The find was made by S. J. States, C. C. Boker, A. M. Barron, F. W. Wagner, John Mouck, and D. C. Price, who located claims. Surface quartz taken from the vein cropping is said to have assayed $80 to $100 per ton in gold and silver. Others are known to have shown but a trace. The camp is about 80 miles north of Reno.

NEW MEXICO

GRANT COUNTY

Of the 45,000,000 tons of copper ore estimated to be available in the mines of the Chino Copper Co., it is figured that 70% can be mined by the steam-shovel method. The construction of the concentrating plant is well advanced. The steel framework is complete, and the concrete floors are being laid; the foundations for the power-plant are about finished, and the 4-mile pipe-line required to convey water from the supply source to the mill has been laid.

SOCORRO COUNTY

(Special Correspondence.)—The Gold Dust Mines Co. is employing 25 men, whose work is confined to the new shaft and the drifts on the vein. The development work performed amounts to about 1000 ft. The property has good surface improvements, including office, storehouse, blacksmith-shop, and residences. Some work is in progress on the Hard Luck claims. The last clean-up at the Deadwood mines amounted to 3500 oz. gold and silver. During the last week 250 tons of ore was milled, and 45 sacks of concentrate was produced. The Ernestine M. Co., for the week, milled 690 tons of ore. The changes recently made in the Socorro mill will give it increased capacity. Good progress is being made in mine development. The Oliver filter, which has been on trial in the mill of the Treasure M. & R. Co., is reported having proved satisfactory, as it resulted in an increased saving of metals. The company's air-compressor is to be driven by electric power, generated at the hydro-electric plant, 3 miles from the mine.

Mogollon, March 18.

OREGON

BAKER COUNTY

The lessees of the Goiconda mine, near Sumpter, have a force of men at work putting the mill in condition to operate, and pumps are to be put in position to unwater the lower workings. J. C. Haas, of Spokane, has taken charge of the work. The Columbia Gold M. Co. is shipping several lots of sorted ore in sacks.

TEXAS

(Special Correspondence.)—The mining bill failed to become a law at the recent session of the legislature. The measure was generally favored by the members of both Houses, and would have passed had the session extended a day or two longer. Some criticism is being made by mining men of the lack of aggressiveness on the part of the legislators who had the bill in hand in not pushing it through promptly. Governor Colquitt will convene a special session of the legislature in July or August, and

pressure is being brought to bear to get him to submit the proposed mining law as one of the subjects for consideration at that session.

Austin, March 15.

UTAH

BEAVER COUNTY

A new ore-shoot opened in the South Utah, on the 600-ft. level, contains ore averaging 4% copper. Its extent has not been determined, but three cross-cuts are being driven, and cross-cutting will be done on the 700-ft. level to find it there. The annual report of the Horn Silver shows a net profit for the year of $10,342, and total cash balance of $47,358. Production was 3,170,146 lb. lead, 52,229 lb. copper, 337,776 lb. zinc, 20,644 oz. silver, and 174 oz. gold. Work is to be resumed on the Utah United, out from Milford, the intention being to sink the shaft from 420 to 500 ft. depth, and drive for a vein that has been followed from the surface to the present lowest workings. The Revenue company is trying to place 330,000 shares of treasury stock in the East to provide a fund in excess of $100,000 to enable it to enlarge and modernize the old mill. This should give the mill a capacity of 200 tons per day. The plans include putting on a traction engine to haul the ore to the railroad at Newhouse.

JUAB COUNTY

New equipment, recently purchased and partly put in position, at the mine of the Chief Con. at Eureka, cost the company $75,000. It includes an air-compressor having the capacity of 1500 cu. ft. of free air per minute, and a double-drum hoist. Development work on the lower levels is being extended into the territory under the town of Eureka, as well as in the opposite direction. Ore-shipments are being made regularly.

SALT LAKE COUNTY

The Utah Copper Co. has 22 steam-shovels at its property in Bingham canyon, 18 of which are in constant use. Twelve of these are used in stripping, two for loading ore, and others are used alternately in loading and stripping. It is reported that 12,000 tons of ore per day is being concentrated at the two mills near Garfield. This ore is said to assay an average of 1½% copper, and for the month of February the extraction was 71%. The Garfield & Bingham railroad, being built by this company, is expected to go into service by June or July, when the ore will be hauled to the mills in trains of 40-ton cars. According to calculations, the cost of transportation will then be 10 to 12c. per ton less than the present cost.

Another victim has been added to those who lost their lives in the snowslide at the property of the Utah Mines Coalition Co. six weeks ago. One of the men who was buried under a mass of snow contracted pneumonia from the exposure and died in the hospital recently. The Columbus Consolidated has levied an assessment of 10c. per share, to bring in $28,000, which is to be used to pay outstanding debts and install a pumping plant, whereby the workings may be unwatered and the orebodies below the 400-ft. level can be reached. Ore shipments from the Burro mine are to be commenced a month earlier than usual, owing to the light snowfall. This property is only eight miles north of Salt Lake, in the Wasatch mountains. It is well equipped to produce on a small scale. A discovery of 'Utahlite' has been made in the western part of Box Elder county. This mineral was so named by George F. Kunz, an expert lapidary, because so far it has been found nowhere except in Utah. It resembles turquoise in appearance and composition, but is higher in alumina and lower in phosphorus and water. It was found in a circular lode which has been opened to a depth of 20 ft. The Utah & Nevada Prospecting Co. has been organized in this city, with the intention of prospecting and exploring in Utah and Nevada.

SUMMIT COUNTY

The Daly-Judge Mining Co. has entered into a contract with the International S. & R. Co., whereby the output of the Daly-Judge mine and mill will be shipped to the plant of the latter company near Tooele. Last year there was shipped from this Park City mine 9106 tons of crude ore, 47,002 tons of concentrate. The former had an average of $26.14 and the latter an average of $28.45 per ton.

WASHINGTON

SPOKANE COUNTY

(Special Correspondence.)—W. C. Gates, of Spokane, Washington, has acquired 2228 acres of placer ground, situated on the Rio Torredamba, 600 miles inland from the Peruvian coast, and is organizing a syndicate to take over the property and operate it. He claims his ground will average 20c. per yard, and that much of it will sample as high as 80 cents.

Spokane, March 15.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Ore from the Toad Mountain Consolidated at Nelson is being tested by the Elmore oil process in England. If the tests show this process to be effective, it is likely that it may be used for treating local ores. Another payment has been made to the Hall M. & S. Co. on account of the Nelson smelter and local mineral properties. The zinc-lead miners of this district are trying to effect reciprocity between Canada and the United States on zinc-lead and like products. A few politicians with ulterior motives are stirring up the fruit-growers of this section against reciprocity. It is doubtful if it would affect the fruit-growers here at all, and the zinc-lead and coal miners favor reciprocity with the United States. An offer of $25,000 has been made to the Great Northern for the abandoned Kaslo & Sandon railway, by a syndicate of local lead miners who wish to put the road in running order again so that they may get the ore from their mines to the lake. The new orebody in the Rambler-Cariboo mine has been opened on the 700, 800, 900, and 1050-ft. levels. A 4500-ft. adit will serve as an outlet for this ore, and raising from this level is in progress. On the 1050-ft. level the orebody has been penetrated for 200 ft., showing for more than 60 ft. in length an average width of 5 ft. of clean ore, of as high as 250 oz. silver and 70% lead. Steps are now being taken to move the Rambler-Cariboo concentrator from its upper site to a point near the outlet on the 4500-ft. level.

Nelson, March 11.

The Standard Silver-Lead M. Co., controlled by Patrick Clark and associates, has let a contract to B. C. Riblet to build for that company an 8500-ft. aerial tramway from the portal of No. 6 adit of the Standard mine to the ore-bins, the latter being situated at the site of the proposed concentrator at Silverton. The plan is to build the mill this season and have it ready for work as soon as the tramway shall be completed. The intention is to ship first-class ore and concentrate to the smelter at Trail. Mr. Clark has an option on the stock of J. A. Finch, of Spokane, and that of George Aylard, of New Denver, which if taken up will give him 65% of the entire issue.

MEXICO

SONORA

(Special Correspondence.)—The Mines Company of America has finished the re-treatment of the old tailing at La Colorada, and is now operating entirely on ore from the Creston and La Colorada mines. The aerial tram system has been rearranged so as to distribute the ore as required to either the Butters or the La Colorada mill, from either mine. The use of electrolytic precipitation at the Butters mill, installed because of the presence of copper salts in the tailing from the pan-amalgamation process, has been abandoned, and the loaded solution from this mill is piped to the La Colorada slime-plant for zinc-dust precipitation. J. E. Clennell, of London, is at La Colorada engaged in making investigations of some of the rebellious ore from the district and in cyanide experiments.

Minas Prietas, March 18.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

FRED F. FREDLUND, of Longyear & Hodge, was in San Francisco this week.

ALEXANDER LEGGAT, recently in Arizona, was in San Francisco, on his way back to Butte.

W. W. WILLIAMS has gone to Nevada to look into the reported gold discovery north of Reno.

J. T. TERRY, who spent some time in cyanide work in Montana, has returned to San Francisco.

FRANK J. DAVEY, lessee of the Bonanza mine, near Bossburg, Washington, was recently at the Tacoma smelter.

JESSE J. MACDONALD will be in Riverside and San Bernardino counties for a week, making mine examinations.

THEO. E. DICKEL has left the Minas de Tajo, and has gone to the Republic Mines Corporation of Republic, Washington.

OLIVER REECE, superintendent of the Economic mine, near Angels, California, started March 21 for the new gold camp in Washoe county, Nevada.

E. W. KING, J. H. BARRETT, and H. S. CHAPMAN, of the Rawhide Coalition and Rawhide Queen mines, of Nevada, were in San Francisco this week.

FRANK J. MURPHY, formerly superintendent of the Yampa smelter, Bingham, Utah, goes to Australia to become superintendent of the Great Cobar smelting plant.

Among the passengers sailing from Seattle to Alaska on March 16 were the following: WILLIAM HAWKINS, for Kenai peninsula; S. F. HUNT, for Knik; W. G. CASSELS and wife, and A. MCVICKER, for Fairbanks; W. A. STEEL, for Cordova; ANDREW NERLAND and a party of five, for Iditarod.

OBITUARY

A. D. GASSAWAY, who died at Berkeley, California, March 19, after an illness of several months following a severe operation, was one of the most capable of mining engineers who obtained their experience in the California placer mines. He was born and raised in Nevada county, and was familiar with hydraulic mining methods from his youth. Later he turned his attention to dredging, becoming the first superintendent of the Lava Beds Dredging Co., and still later he devoted himself to making examinations and reports on placer properties. To this work he brought a high and deserved reputation for ability and integrity, and his services were much in demand. He returned last year from Siberia where he had been in the service of the Lena Goldfields Ltd. He was not entirely well when he reached home, and lived quietly at Berkeley up to the time of his death. Mr. Gassaway was a thorough student, a hard worker, and one who took the duties of his profession seriously. He will be much missed by his friends and professional associates.

H. P. GARTHWAITE, who died on the Isthmus of Panama, March 17, as a result of congestion of the brain, was a well known Californian mining engineer who first became interested in mines through business relations with Charles Butters. Mr. Garthwaite was at that time a banker, but after joining Mr. Butters, he devoted his whole time and energy to mining. First in South Africa, and later in Salvador, he operated with unusual success. He was constructive by instinct, and enterprises under his charge built up rapidly. He found time for much besides business and was an important factor in public affairs in Salvador. Probably his largest piece of public service was the reconcilement that he, mainly, effected between Nicaragua and Salvador at the time he served as special commissioner for the latter country in connection with a boundary dispute. He was largely influential, also, in straightening out the tangled financial affairs of Salvador, and that Government and its people join Americans and mining men everywhere in regret at his death.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

FORFEITURE OF CLAIM—NONPERFORMANCE OF ASSESSMENT WORK

The nonperformance of assessment work by the locator of a mine will not forfeit his claim thereto unless there has been a valid location by another, and a person who did not himself make a valid location cannot question the sufficiency of the assessment work done by the original locator.

Knutson *v.* Fredlund, (Wash.) 106 Pac. 200. Jan. 1910.

RIGHT OF STOCKHOLDER TO VOTE ON RATIFICATION OF MORTGAGE

The statute of California provides that for all corporate elections there must be a majority of the subscribed capital stock or of the members represented, either in person or by written proxy, and that each person acting in person or by proxy must be a bona fide stockholder having stock in his own name in the books of the corporation at least ten days prior to such election. This statute is construed to apply to a vote taken at a meeting of the stockholders of a mining corporation called to ratify a mortgage of its mining ground proposed to be made by its directors, and a bona fide stockholder within the provision of this statute need not necessarily be the owner of the stock, but it is sufficient if the stock stands in his name in good faith for a proper purpose either for himself or in trust for another.

Royal Consolidated Mining Co. *v.* Royal Consolidated Mines Co., (Cal.) 110 Pac. 123.

RATIFICATION OF MORTGAGE BY STOCKHOLDERS OF MINING COMPANY

Under the statute of California requiring the mortgage of a mining company executed on its mining lands to be ratified by the holders of two-thirds of the stock of the corporation, it was held to be a sufficient ratification where one of the directors of such a corporation was the bona fide holder of two-thirds of the corporate stock, and his act as such director in executing the mortgage operated as a ratification by two-thirds of the holders of the stock as required by the statute, to give the mortgage validity. In determining who are the holders of the legal title to two-thirds of such stock, in order to ratify such a mortgage, the courts may look behind the apparent ownership and sustain a ratification made by the beneficial owners of the required amount of the stock. But such a mortgage lacking the requisite ratification can not be rendered valid by estoppel.

Royal Consolidated Mining Co. *v.* Royal Consolidated Mines Co., (Cal.) 110 Pac. 123.

MINE APPLIANCE OR FIXTURE—SALE ON EXECUTION

Engines, boilers, mills, pumps, and electric hoist firmly bolted to the substructure on which they rest and the superstructure and engine house surrounding them, sufficiently affixed to the soil for mining purposes, and a head-frame at the mine, the base of which was originally sunk into the earth to make it level and substantial for use for mining, together with the hoist and transformers, forming integral parts of one mechanism essential to the operation of the mine, are fixtures and are not subject to sale on execution as personal property under the laws of Nevada. This rule applies where a buyer of chattels, under a contract stipulating that the same shall be regarded as the personal property of the seller, with the right of removal until paid for, and thereupon attaches such property to real estate so as to make the same fixtures, they do become fixtures as against every other person except the seller, and cannot be sold as personal property on the execution against the buyer. A sale of property as personal property at an execution sale is invalid where any of the articles sold were fixtures.

Arnold *v.* Goldfield Third Chance Mining Co., (Nev.) 109 Pac. 718. July 1910.

PRODUCTION OF FULLER'S EARTH IN 1909. By F. B. Van Horn. Adv. Chapter, Mineral Resources U. S., 1909. U. S. Geol. Surv. Pp. 6. Washington, 1911.

POTASH SALTS; THEIR USES AND OCCURRENCE IN THE UNITED STATES. By W. C. Phalen. Adv. Chapter, Mineral Resources U. S., 1910. U. S. Geol. Surv. Pp. 24. Washington, 1911. An interesting general account of the salts.

MINERAL PRODUCTION OF ONTARIO FOR 1910. Bureau of Mines, Bull. 7. Pp. 8. Toronto, 1911. This bulletin, issued by T. W. Gibson, deputy minister of mines, shows a total yield valued at $39,232,814. Silver to a value of $15,436,994 was the largest single item.

DENUDATION AND EROSION IN THE SOUTHERN APPALACHIAN REGION AND THE MONONGAHELA BASIN. By L. C. Glenn. U. S. Geol. Surv., Prof. Pap. 72. Pp. 137. Ill., index. Washington, 1911. A scientific study of the causes of erosion and effects of lumbering, mining, farming, and other industries. Especially timely and valuable.

OIL RESOURCES OF ILLINOIS WITH SPECIAL REFERENCE TO THE AREA OUTSIDE OF THE SOUTHEASTERN FIELDS. By R. S. Blatchley. From Bull. 16, State Geol. Surv. Pp. 138. Ill., maps. Urbana, 1911. This is a concise but helpful summary of existing information with suggestions regarding anticlines and terraces, such as are of great interest to oilmen.

PRELIMINARY REPORT ON THE MINERAL PRODUCTION OF CANADA, 1910. By John McLeish. Dept. Mines, Mines Branch, No. 102. Pp. 21. Ottawa, 1911. A brief summary report issued with commendable promptness and showing a production valued at $105,040,958; an increase of $13,209,517 over 1909. Of the total, Ontario produced 40.95% and British Columbia, 23.37.

ANNUAL REPORT OF THE DIRECTOR OF THE MINT, for the fiscal year ending June 13, 1910. By George E. Roberts. 8vo. Pp. 288. Washington, 1911. This volume includes the usual tables and detailed account of the operations of the Bureau of the Mint, supplemented by some unusually interesting monetary statistics of foreign countries, compiled by Mr. Roberts through direct correspondence.

ANNUAL REPORT OF THE SMITHSONIAN INSTITUTE. By C. D. Walcott. Pp. 751. Ill., index. Washington, 1910. This volume, like those preceding, consists of the annual report of the Institute bound together with some thirty-five reprints from various sources of papers and addresses by leading men of science, dealing with the progress of science during the year under review. It is a mistake, however, to include in a large collection of reprints a few original papers of value, and thus bury them from easy access by the workers along these lines. It would be an improvement to publish the report of the Institute in a separate volume and thus decrease somewhat the size of the present too bulky volume, and a further improvement would be to include in each volume a statement of at what price and where the volume can be obtained. With the present wide diffusion of knowledge the articles here gathered together would be read with interest by a notable proportion of the general public, and if the obtaining of the volume were made more easy large numbers of them would undoubtedly do so.

THE VULCAN IRON WORKS

From the standpoint of economical shop management possibilities, the new plant of the Vulcan Iron Works in Seattle, has been pronounced by experts in construction and operation, a model to be emulated. It was not built piece-meal, but stands today the result of an intelligent, skilful plan, carefully worked out in full before a single pile was driven for any part of the foundation from which it rises.

In the original outlay, economy was not considered, not that money was squandered; but the whole thought was to design and erect a plant, completely equipped with time and labor-saving devices as well as with extraordinary regard for the comfort and well being of its employees. To accomplish this combination, no expense was spared. As it stands, the plant called for an outlay of $2,000,000, aside from the cost of the twelve-acre site. The plant was designed by and constructed under the personal supervision of H. P. Strickland, president and general manager for the company. The thirteen buildings are so grouped as to facilitate inter-communication. Raw material starts in at one end, progresses through the various departments, and comes out at the other in the finished product, without doubling back on itself. To make a tour of this shop is a liberal education in factory management. Waste motion has been eliminated in a hundred different ways. Pig iron is unloaded from a spur at the rear of the cupola. It makes the round of the shop with all possible dispatch, passing from the foundry to the machine shop, by means of an overhead electric crane, which makes deliveries at every machine. All machinery is of the latest type. There is no great amount of belting to be kept up, as each machine is directly driven by its own motor.

Glimpse of The Vulcan Iron Works, Seattle, Giving Idea of Exterior, the Floral Decorations and General Cleanliness.

The railroad siding runs into a pit, leaving the flat-car top flush with the floor-level of the loading platform. This makes it possible to handle all heavy stuff on rollers and does away with raising or lifting. From the standpoint of economy, this feature in itself is of great importance. The plant has direct communication with six transcontinental railroads and easy access to the water-front on Puget Sound. An industrial railroad runs through the entire plant. It consists of 24-in. gauge trackage, connecting all parts of the different shops direct with the shipping department. There are fifteen turn-tables, so arranged that the shortest cross-cuts can be made, when desirable.

Crude oil is used for fuel under the boilers and in the forges, because it has been found much cheaper and cleaner. No labor is required to feed the fires. Electric power is used extensively, and wherever practical, compressed air has been adopted in the foundry and structural and machine shops. The plant is equipped with eight overhead cranes, which transfer the heavy materials to any part of the plant. This feature alone is a great promoter of shop economy, as it does away with a lot of labor. Then, there is a 25-ton stiff-legged derrick to load the motor trucks for making city deliveries.

Sheet metal and ribbed glass have been used throughout so as to get the maximum amount of daylight. No employee of the Vulcan Iron Works ever has to use a candle to see any part of the work he is engaged on. The results for this reason are much more satisfactory than in a dingy iron and steel works, as they are generally found. Neither is there any débris or dirt to be seen anywhere, for Mr. Strickland has found that cleanliness is as desirable about the shop as in the home. As a result of the attractive washrooms, reading quarters, and recreation provisions, the Vulcan Iron Works finds itself able to draw on the best mechanics in the Northwest. It enjoys the self-satisfying novelty of having applications from the most skilled mechanics on file, all the time. Aside from the necessities, the plant has been beautified. The exterior is embellished with flowers, plants, and shrubs, that remain green the whole year around, owing to the mildness of the Puget Sound climate.

Machine Shop View, The Vulcan Iron Works, Seattle, Showing How Light it is.

With this splendid equipment, the Vulcan Iron Works is able to build the most efficient mining machinery. Its stamp-mills, ore-chushers, tramways, hoists, ore-cars, etc., are giving general satisfaction wherever adopted. The brand, 'Vulcan-Made,' has come to mean 'past the experimental stage.' The same applies to all of the logging supplies and sawmill equipment that the company builds. In addition, it is turning out large amounts of structural steel. The fact is, Mr. Strickland has so systematized his new plant that experts who have recently visited it, declare that for scientific and economical operation and for the comfort of its men, the Vulcan Iron Works is without equal. For that reason it is able to turn out adequately and most economically anything in the line of fabricated iron and steel.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

TABLE OF CONTENTS

EDITORIAL

GEOLOGISTS and mining engineers around the world join in extending sympathy to the family and friends of S. F. Emmons, who died at Washington, March 28. At another time we shall speak more in detail of him and his work.

THE American Electrochemical Society meets in New York this week. The principal subject to be discussed is the use of electric furnaces in the iron industry. The Claney cyanide process will also come up for consideration.

ILLINOIS coal operators and miners have joined in urging better support of the State Geological Survey and the Department of Mining of the University. Evidently both have commended themselves to those most directly concerned. We are especially glad to see that funds are asked for establishing miners' institutes comparable to those maintained for the benefit of teachers and farmers. More intelligence in the ranks is needed.

CIVIL SERVICE examinations will be held April 12 and 13 to secure a list from which appointments may be made to positions of junior mechanical and junior mining engineers in the Bureau of Mines. Candidates must have the equivalent of four years training in a reputable technical school. Application should be made to local civil service boards, and the law requires that each person be examined within the State of which he is a citizen.

FEDERAL authorities have raided the various offices of A. L. Wisner & Company and charges of using the mails to defraud have been lodged against the principals. Among the companies that this firm has been promoting were the following: Thirty-three Consolidated Oil Company, Mutual Oil Company, Homestake Gold Mining Company, Little Badger Mining Company, Sycamore Oil Company, Valencia Copper Mining Company, Black Oak Gold Mining Company, Eureka Oil & Gas Company, Mount Jefferson Mines Consolidated, Empire Gold Mines Limited, California & New York Oil Company Consolidated, California Monarch Oil Company, United Tonopah & Goldfield Mines, Manhattan-Nevada Gold Company, Philippines Plantation Company, California Diamond Oil Company, Murchie Extension Gold Mining Company, and the Amalgamated Mining & Oil Company. This is a glittering array of names well calculated to lead small investors into thinking that wealth could be had for the asking.

FOR the autumn meeting of the American Institute of Mining Engineers in San Francisco arrangements have been made to secure a special train to bring the visiting members from the East. The start will be from Chicago on September 30, and a day or two each will be spent at the Grand Canyon of the Colorado, Los Angeles, Santa Barbara, and Del Monte, the party reaching San Francisco October 10. The local committee will hold a meeting today to plan for the meeting.

MEXICAN conditions seem likely to improve shortly, as negotiations looking toward peace are evidently in progress. The resignation of the entire Mexican Cabinet is a striking evidence of the desire of the Government to conciliate public opinion. The men who retire have been large factors in the making of modern Mexico. In the years to come their names will be remembered and honored by all. They have given much to the public service and in now sacrificing personal ambition to the public good, they give proof of the deep-seated and wide-spread patriotism which actuates the ruling class in Mexico. It has been all too common to impute to the President alone the great work that has been done south of the Rio Grande. Those familiar with conditions in Mexico, however, know of many cases of disinterested public service by men of classes that in the United States have too often held aloof. There have been many who have served quietly and effectively, recognizing the faults of the present system, but putting their faith in the God of things as they are, to the end that in time the God of things as they should be shall reign.

BUCKHORN in Eureka county, Nevada, will have no need to get out an injunction to protect its own. The new camp that so boldly attempted to appropriate the name is no more. The story is short. For years Fort Sage mountain has been given up to sheep, sagebrush, and silence. February 15 canny herders and ranchers located a group of claims, but preserved the silence till March 19. Sunday afternoon Reno was filled with rumors of a great 'strike,' of veins 200 feet wide, of assays showing $80 to $100 in gold, of a nugget of $6000! Telegrams flew and the rush was on. Monday people flocked into the district from all sides. Tuesday a New York 'capitalist' bought two claims for $1200. Wednesday morning preliminary steps were taken at Reno for organizing a $1,000,000 corporation to operate in the district, and more strangers arrived on every train. The same afternoon the McCullom Company at Reno completed assaying four samples taken across the lode by Mr. W. W. Williams, an experienced San Francisco mining man. Anxiously the results were awaited. They showed no silver and but a trace of gold. Wednesday night the Pullmans and chair cars were crowded going out from Reno, from which place late arrivals returned without going farther north. The New Yorker has his claims; there has been an increase in the amount of money in local circulation; and sheep, sagebrush, and silence reign again.

Industrial Safety Association

Editors and other representatives of the technical press were guests of Mr. David Williams at a dinner at the Engineers Club in New York recently, where the work of the newly organized Industrial Safety Association was discussed. Mr. Williams, in introducing Mr. F. R. Hutton, president of the Association, sketched its purpose, and mentioned that its ultimate object is to create a better feeling between employee and employer by the safeguarding of the former from injuries which simple expedients in many cases would avoid. Mr. Williams went on to say that the idea of the Association was not exactly philanthropic, as it was the intention to encourage corporations and other employers to adopt means for insuring the safety of workmen, and thereby to anticipate, and perhaps forestall, legislation influenced by labor, making for the same ends. Reference was made to a company controlled by Mr. Williams which had felt justified in permitting its employees' insurance to lapse by reason of the ideal conditions under which the mechanics worked. Mr. Hutton, who is consulting engineer to the Department of Water, Gas, and Electricity of New York City, illustrated his talk by pictures taken under actual operating conditions in various large industrial establishments which had adopted devices making for the safety of the workmen. Many of the pictures thrown on the screen were of simple devices and expedients, costing little, but obviously of great value in protecting men against injuries which so often result from carelessness on the part of those injured. He mentioned that one of the principal objects of the Association was to secure the adoption, if possible, of a standard set of shop rules. This object, if attained, would result in complete familiarity with working conditions when employees went from one works to another. His talk met with very favorable reception, much interest and enthusiasm being evinced by those attending the dinner. Before adjourning to the business offices of the Association, where an interesting exhibit of safety devices was on view, a few words were said by Mr. Henry R. Towne, president of Yale & Towne Manufacturing Company. Mr. Towne made referenee to one of the pictures shown during Mr. Hutton's talk, which portrayed a 'first aid to the injured' room in one of the steelworks, and said it much resembled a room in the plant of his own company. At this plant, 3000 workmen are employed, and during the year 1910, 14,000 minor injuries were treated in the small dispensary. A trained nurse was in constant attendance, and, when necessary, a physician was called in. Mr. Towne said that the total cost for the treatment of employees during the past year was only $1500. Consideration of the iron and steel industries will be followed by that of the railroads, and it is then expected to take up mining. Much interest has been aroused among the large employers of labor, and it is believed that the Association will have a most useful and successful future.

Floating Mines in London

In the early days of mining in the United States, mines were expected to pay for their own development. The capital invested was almost entirely that which came originally from the ground, but the amount needed was small. It was still possible to find veins that showed rich ore at the surface, and with only the most modest equipment, or none, mines could be opened and developed. Unfortunately this is rarely true at present. The big surface bonanzas are gone, and to succeed now it is necessary to prospect deep ground systematically, or to work on such a large scale as to make a profit from low-grade ore. Either course demands large capital investment, and where to obtain the money is the acute problem in many a district. It is not within the province of a technical publication to promote individual enterprises, no matter how worthy, and the *Mining and Scientific Press*, as well as those concerned in its management, remains aloof from all promotion. At the same time, it may be helpful to state briefly exactly what may be expected when a worthy property is suitably presented to those who have money to invest in mines.

London is now the greatest mining market. Great Britain receives a yearly return of $750,000,000 from investments in foreign lands, and of this sum, metal mining, exclusive of iron, contributes $150,000,000. Approximately one-half of this is the return on investments in gold mines; for the great gold mines of the world belong to the English. In Great Britain, as elsewhere, men who have made money in mines are usually willing to try again, and the English system of permanent companies managed by engineering firms, favors re-investment of the company surplus in a new mining enterprise. Many of these firms have established enviable reputations and are able to command large amounts of capital for any enterprise that can be shown to be profitable. Whether or not the ore exists and can be mined at a profit, determines whether or not the investment will be made, rather than the proposed scale of the enterprise. It is evident that only properties that 'will stand examination' can be handled under these conditions, but any such property can secure on fair terms the money that it needs. Just what those terms are may be illustrated by a few examples.

It must be remembered that English investors are not inclined to pay out a lot of cash unless some certain profits are in sight. If a property has large prospective as well as certain profits, the owner can get the full cash value of the certain profits, and the acquiring company will, in addition, find the cash necessary for the equipping of the property. Such properties are seldom obtainable, and the more common case is that of a property which has sufficient probable profits to warrant its full equipment but not enough to warrant a cash payment to the owners. In such cases the financier is usually willing to put his cash for equipment against the owner's mine. The interest retained by the owner would depend on the certain profits as well as the prospective profits. For example, take the case of a mine that has available 20,000 tons of $13 ore on which a saving of $11 can be made, the working cost being estimated at $6 per ton, and where the ore, both at ends of drifts and in its bottom, is of good grade. Such a property would warrant the erection of a plant with an initial capacity of 50 tons per day. Presuming that this would cost $50,000 to $60,000, then the owner would be given an interest of perhaps 45 per cent.

Or, taking the case of a mine that has 60,000 tons of $7.50 ore on which a saving of $6 can be made at a working cost of $4, again with good prospective profits, an equipment for handling 100 tons would be warranted. Such a plant would probably cost $100,000, and the owner would not receive more than a one-third interest, possibly one-fourth, in a company with the required working capital. In case of a property with several exposures of outcrop, over a considerable length, these exposures in width and length warranting the expectation of profitable exploitation, the vendor would be given a quarter interest in a company with sufficient working capital to prove the value of the property. In all cases the owners would have to submit as full reports as possible, and if these are not made by some one of known ability, then the owners would have to deposit some cash as a guarantee that the property was not misrepresented. The titles should be perfectly clear, preferably United States patent.

Another method of dealing with properties of merit is to lend sufficient money to the owners to place the mine in a productive stage. In this event there must be sufficient certain profit in sight to repay the lender the amount of his loan plus some remuneration. This, calculated as interest, appears high, but in the end the owner has a fully equipped property without parting with a large interest in it. The amount of the remuneration varies with the richness of the property. Under this plan the two cases cited above would work out in the following manner:

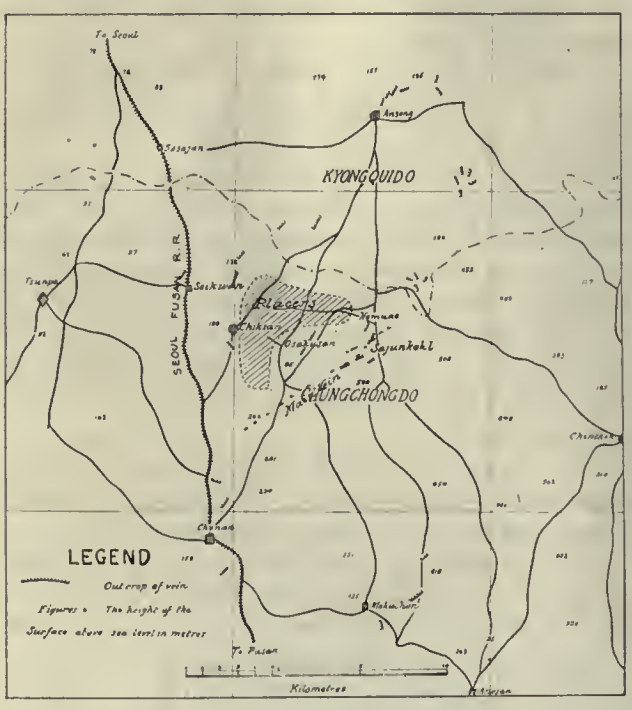
(1) Amount to be lent, $60,000; remuneration to be in three forms, including (*a*) interest on amount lent at 6 per cent per annum until loan repaid, (*b*) a percentage of the profits amounting to one-quarter of one per cent, for each $1000 lent, equal to 15 per cent if $60,000 be lent, and (*c*) a bonus of an interest in the property of 5 to 15 per cent. (2) Amount to be lent, $100,000; remuneration to be in three forms, (*a*) interest at 6 per cent per annum on amount lent until repaid, (*b*) a percentage of profits amounting to one-eighth of one per cent for each $1000 lent, equal to 12½ per cent if $100,000 be lent, and payable during not less than two years after production on a full scale has begun, and (*c*) a bonus of an interest in the property of not less than 10 per cent. There are many other ways in which mining properties can be financed, but the foregoing are examples from which anyone can make calculations as to what can be actually expected in London.

The Chicksan Mines, Korea

By Thomas T. Read

Korea is widely known as a mineral region of note, chiefly because of the conspicuous success attained by the Oriental Consolidated Mining Co., whose properties at Taracol, Chittabalbie, and Tabowie, 100 miles northeast of Pyengyang, have produced $9,500,000 in gold bullion and are still active. The copper mines of northern Korea were briefly described in the London letter of last week's issue. The Chicksan mines, 40 miles south of Seoul, are less well-known, as the exploration which has been in progress during the last few years has only recently reached a stage where an estimate of the value of the district could be formed. Recent results, however, have been of so encouraging a nature that their probable future importance makes a a description of the Chicksan mines of interest.

Map of Southern Korea.



Map of Chicksan Mining Concession.

The Korean Exploration Co., which is jointly owned by American and Japanese interests, obtained from the Korean government a concession to select mining lands, using Chicksan (see accompanying map) as a centre, and extending 13 miles east and west and 8½ miles north and south. Careful exploration work has been carried on throughout this area. The headquarters of the mine are at Homune, a small village in the prefecture of Chicksan, 40 miles to the south of Seoul. Seikwan station, on the Seoul-Fusan railway, is 9½ miles to the west, while Tsunpo harbor is 6 miles farther west. The mine is connected with the railway by a good road, so that transportation by bullock cart is easy and cheap, though not rapid.

Fig. 1. Stamp-Mill, Kurangkohl.

The deposits owned by the company are both veins and placers. Their relative positions and extent are seen by reference to the accompanying map. The territory covered by the concession consists of low rolling hills of granite and schist. The veins outcrop on the hills and the open valleys adjacent are filled with the placer deposits. More than seventy veins have been discovered throughout the concession area, large numbers of these having been previously worked by the natives according to their primitive methods. The largest vein has been traced for nearly five miles of its length and shows a notable gold content throughout, but only rich enough for profitable working

Fig. 2. Placer Workings.

at several points along its course. The ore in the three mines now working on this vein averages $14 to $20 per ton, rich streaks occasionally being found that run as much as $90 per ton. The present explorations indicate that it is safe to count on a very large tonnage of ore that will run $10 per ton or better. The richest ore is found in a vein at Homune, about a half-mile to the northwest of the main mine openings. This is very celebrated among the Koreans, having been the scene of extensive native workings that had to be discontinued on account of the water. The company began to explore this by means of an air-shaft, a pump-shaft, and a double-compartment main shaft. By the time these had reached a depth of 90 ft., 145 ft., and 230 ft., respectively, so much water was encountered that work was temporarily stopped until

Fig. 3. Sluicing.

more adequate pumping facilities could be installed, and it has not since been resumed, as efforts have been concentrated on exploring the main vein. Enough work has been done, however, to show that the vein is of good size and has an average gold content of $44 per ton. In numerous other places veins have been found, some of them possessing even richer ore, but no effort has been made to exploit them as yet, the management wisely considering that a greater profit will be obtained by working the lower grade ore of the main seam on a large scale.

The main vein is being worked at Sajunkohl, Kurangkohl, and Moonsokohl. At Sajunkohl there is an air-shaft and a main shaft, each about 150 ft. deep, and an adit which connects with a winze that extends to about 175 ft. in depth. The vein as exposed in these workings varies from 3 to 15 ft. in width, usually 4 to 8 ft., having an average gold content of $13 to $15. The ore from these openings goes to a 4-stamp Nissen mill, shown in Fig. 1, where it is amalgamated on plates, and the pulp then passes over tables. The concentrate thus obtained is dried and sacked for shipment to America. About 90% of the gold content is thus recovered. The tailing is stacked in a pile, so that it may be cyanided later. The ore is a hard white quartz, the amount of sulphides present not being very great. No experiments have yet been made as to whether it will be possible to cyanide the tailing from the plates without previous concentration, but it seems

Fig. 4. Native Workings.

quite probable that this may prove to be the case. In that event a high total recovery can be made very cheaply. The cost of shipment of the concentrate to America is rather high, but allows a good profit to be made on this method of disposing of it.

About five miles to the southwest, at Kurangkohl, on the prolongation of the same vein, a second

Fig. 5. Native Workings.

series of openings has been made. A vertical shaft has been sunk to a depth of 110 ft., and a short distance away an adit was driven with the expectation of intersecting the vein. Unfortunately, on intersecting the vein it was found that it had been completely stoped out by the natives to a depth of 60 ft. below the adit-level. A winze was therefore put down and a cross-drift is being driven to connect with the shaft at its 100-ft. level. The vein is wider here, averaging 10 ft., and in one place showing over 30 ft. The gold content is lower, being $6 per ton on the average, although rich streaks have

been found that averaged as high as $90 per ton. There is here a small mill, three Hendy 1000-lb. quadruple-discharge stamps with short plates, the pulp passing thence to a Pinder concentrator. The erection of the mill was not finished at the time of my visit, but the supply of ore from the exploration work at Kurangkohl and from the third opening on this seam at Moonsokohl, 1½ miles farther to the southwest, was already greater than the capacity of the mill.

A few hundred yards from the mine at Sajunkohl there is another opening on another seam parallel to the main seam and about 1000 ft. to the north of it. The vein has a fairly constant width of 4 ft., and the ore-shoot at the surface is 75 ft. in length. It has been followed to a depth of 300 ft., and at that depth has increased to 160 ft. in length, the ore averaging $14 to $16 per ton throughout. It therefore seems probable that a good small mine may be made on this vein, but the extensive working of the large main vein will undoubtedly prove the greatest source of revenue. During the exploration work not a little profit was derived from milling small lots of high-grade ore brought in by native tributers. The company makes only a comparatively low charge for milling, as the native work forms an effective supplement to exploration on the company's account. The total number of veins being worked by the tributers is very great, and not a few of these may eventually develop into valuable mines, but even if no further discoveries are made, those in process of development will undoubtedly prove of very considerable value.

A further large asset is the placer ground which occupies the broad valleys of the two small streams that cut across the main vein. These have been tested over an area of some 300 acres by means of 118 holes. The ground is 19 ft. deep on the average, and has an average content of 13.3c. per cubic yard, about twelve million cubic yards being available. The character of the ground can be seen on the eastern edge of the placer ground, near Seijaro, where the Japanese have been at work for four years. The ground here is 18 to 20 ft. deep. The upper 10 ft. of this, a rather loose soil, is removed by contractors, who load it into the cars of an industrial railway, constructed by the company, and dump it on worked-out ground. The next 6 ft., a bluish clay, is removed in a similar manner, but by daily wage. The gold is contained in a layer of sand 1½ to 3 ft. in thickness. This contains a few stones, but I saw very few that were larger than a man's fist, and there was one solitary boulder in all the workings at the time of my visit. The sand is gathered up in the Korean equivalent of a hod (see Fig. 3), holding 30 to 40 lb., carried up a staging similar to that in the background of Fig. 2, and dumped into the sluice, shown in Fig. 3. The cost of working by this method is about 10c. per cubic yard, and the recovery is about 12c., so the margin of profit is not great. The ground at this place averages 20c. per cubic yard, so there is room for improvement in the saving made. The native method of working is shown in Fig. 4 and 5. The cost of this is slightly less, but the recovery is poor. This ground ought to yield good results on dredging, as the overburden contains some gold, not enough to pay for sluicing it, but which would add to the dredging yield. It is also not at all improbable that the average gold content of the ground may prove to be greater than the results of the test-holes indicated, as the method followed in making the examination is likely to give low results. The character of the ground is such as to make dredging easy.

A further advantage that operators in this territory possess is the low cost of efficient labor. A contract was let for sinking and timbering a 4 by 4½-ft. shaft in easy ground at the rate of $2.70 per foot. The average cost per foot in hard ground is $5. A 16-ft. earth road cost $250 per mile to construct, although it involved making one deep cut and a good deal of filling in crossing the ricefields. About ¾ mile of foot-trail cost $9. The local labor is easily trained to the work, many of the men having worked as tributers. They are industrious, peaceable, and easily controlled; a typical group is seen in Fig. 6. They manifest a tendency to leave off work in order to hold feasts and celebrations of various kinds, but a system of fines quickly corrects this. The highest class of skilled labor, such as carpenters and blacksmiths, is usually Chinese and Japanese. These men naturally command much higher wages. Fig. 7 shows a group of natives at work putting down a test-hole.

The terms allowed the company by the Korean government were very favorable, the essential features being duty-free import and export of machinery and ores, exemption from all taxes, and the payment of a royalty of 25% of the net profits of the operation of the mines. When the Japanese annexed Korea this agreement was confirmed by the Japanese Ministry of Korea, and the company continues to operate under its terms. Possibly the fact that the original concession was obtained by a Japanese syndicate in 1900 may have influenced the viceregal government. Be that as it may, the regulations regarding the use of foreign capital in developing mineral deposits in Korea, which the Chosen government has promulgated, are very liberal and offer foreigners equal advantages with Japanese.

In regard to the other mines of Korea, little can be said at present. In many parts of the country the Korean government prohibited the carrying on of mining operations, and prospecting has been somewhat restricted by the reluctance of the natives to disturb graves, being even more superstitious than the Chinese in this regard. But the Japanese have no such reluctance, in the case of Korean graves, at least, and prospecting may now be expected to be prosecuted with vigor. The lack of facilities for communication and transportation was the greatest handicap to the development of mining, but the telegraph and telephone lines, railroads, and ordinary roads which are now under construction will soon remove this disability. Northern Korea offers an interesting field for exploration, but it is too soon as yet to venture an opinion as to the future possibilities of the area.

West Mexican Mining Camps

By A. L. Sheldon

Mining is now quiet aronnd Hermosillo, Sonora, there being more interest in lands. People are coming and going, examining land, and many sales have been made in the district. Mining men are turning their attention to land, owing to this activity, but this is only temporary. In Colorado, three or four years ago, many mining men entered into land and irrigation schemes. However, the tide has turned, and the outlook for mining in Colorado is said to be better than for years. Above Hermosillo, 20 miles east of Poze, the Las Tajos company has been developing the San Geronimo mine and has constructed a concentrating plant. The ore in the upper levels is an argentiferons galena of high grade. The company was making a good grade of concentrate, but the 20-hp. boiler used to pump water to the mill from the reservoir—a long distance—could not supply the mill and a 65-hp. boiler was installed. They built a dam about 40 ft. high, but it did not

Fig. 6. A Group of Koreans.

entirely fill during the last rainy season. George Powell of Idaho Springs is in charge.

J. M. Curtis is manager of the El Oro mine, about three miles this side of the San Geronimo. He is doing a little prospecting work, but has not yet discovered any well defined vein. The company has expended about $250,000, and has milled not more than 2000 tons of ore of $5 grade. They have sunk to over 400 ft. in depth.

The Sultana, east of Carbo, is shut down, and it is believed the mine is nearly worked out. The Cole-Ryan people took this mine only in order to obtain the Giroux at Ely. The Tecoloto company is putting in a small smelter on its copper property west of Carbo. The greatest activity in mining in Sonora during the past year has been in the Altar district, owing to the successful work of the new Quenner dry-placer machine on the clay-cement placer-beds. Practically the whole area has been located—more than 100 square miles. It is a very dry country. The Epes Randolph company spent over $500,000 building a mill and water plant, trying to treat their material by amalgamation, but it was found impossible, as the clay carried off the gold. The placer deposits have been worked in a small way for generations, the dry-washers doing the best work, but the Quenner invention has changed everything. It now looks as though Nature would have to give up the gold in this extensive deposit. The Quenner machine is practically a large barrel revolving slowly on a horizontal shaft. Chains are attached to the shaft inside, with hammers on the ends of the chains. The latter are arranged in lengths so as to give the material a centrifugal motion, which separates and discharges at one end all of the rock. The finely pulverized cemented material drops through a screen and is carried to one side, while the gold is separated in a dry blower that also makes a black-sand concentrate sometimes running as high as $1000 per ton. As the new mining law does not allow one to work his claim until title is received, there are as yet but few machines in operation, but these few are doing very satisfactory work. The machines are made in several sizes and handle large tonnages cheaply.

At Minas Prietas the Creston Colorado people are

Fig. 7. Koreans Drilling.

sinking a new working shaft in virgin ground, where a recent discovery of ore has been made. The old shafts and workings are in a dangerous condition, owing to the extraction of so much ore from this large vein, without sufficient filling of the stopes. The Mines Company of America controls this mine, the Dolores, near Madera, and El Rayo, near Santa Barbara, Chihuahua; also La Dura mines on the Yaqui river, above Corral, where the Yaqui river branch of the S. P. railroad connects with the main line in Sonora. The La Dura mines have been operating for years, and now having the railroad at the mines, the company will be able to handle its low-grade ore. George A. Schroter is consulting engineer and was recently at the mine outlining the work. La Junta mine, which is near Bacari, just south of the Quierago-Alamos district, was discovered within the last year. The owners shipped $65,000 worth of gold ore during the first six months. Now G. W. Smith at Savia is milling the low-grade ore, with satisfactory results. La Junta mine is owned by a number of Mexicans, who divide the ore pro rata at the mine. The mine is supposed to be on the Mother Lode, which extends from near Alamos to La Dura. Just south of La Junta, Wilson & McCarthy are developing their property on the same vein. They have good ore. Clementi Ibarri owns

the adjoining ground to the south, which gives fair results, from surface assays. All that section has been located for several miles. Where the vein is in the porphyry, or along the contact of granite and porphyry, there are good indications of opening mines. This mother lode, at the north end La Dura and at the south end Promontorio, is mostly silver. At Minas Nuevas, A. J. Yeager is cyaniding the old tailing on the Zambona mine, which is on the mother lode, and is turning out 12 to 15 bars per month, each worth $1000. He turns bullion in to the old Government mint office at Alamos. J. R. Hendra has been developing for several years the old San Domingo mine. He has large reserves of ore blocked out, and recently started his 10-stamp mill and concentrating plant, and is shipping a good grade of silver-gold-lead-copper concentrate, with some zinc. Courtenay De Kalb, manager for the Pacific Smelting & Mining Co., recently offered to contract for his product for 10 years. The Quintero, owned by a French company, about one-half mile south of San Domingo, on the same vein, but on contact of granite-porphyry, is now idle after paying dividends for years. At 1500-ft. depth the vein splits, and the one in the granite was followed with no results. The vein between the San Domingo and Quintero is in the granite, and so far as developed is of no value. The old Promontorio, in porphyry, and adjoining the Quintero on the south, after producing continuously for 100 years, is now idle. There are immense dumps which will be worked over again some day. I measured a tree 2 ft. in diameter on one of the dumps. The mine is only 800 ft. deep, and ought to be a good property today under proper management. Pierce Brothers at Alamos are doing some development on their property north of San Bernardo on the Chinipas road. They have some high-grade telluride ore. Seeley W. Mudd, of Los Angeles, gave up his option on Piedras Verdas, 15 miles north of Alamos, after doing some prospect work with the diamond-drill. At Chinipas, George Stevenson, manager of the Zapote mill and mine, is repairing the 10-mile ditch for water-power, overhauling the mill, putting in a cyanide plant, and intends to do away with the 18 miles of railroad to the mine, using a gravity tram. The company has recently acquired the Miguel Torres ground adjoining its property, in which the company had an interest. On Babehuahua creek, southeast of Alamos, Harry Rabb, an old San Juan man, is doing some work on the placers. During the past ten years that I have known these placers various companies have spent large amounts on them, but no one has made a dollar. The placer mines of Mexico are pretty thoroughly worked out. Near there, at Agua Caliente de Avila, there is a copper prospect called the Copper Iron King, a large gossan capping carrying gold and silver, and impregnated with copper. It has every appearance of making a copper mine with development. The mining industry around Choix is not very active. Since the Lluvia de Oro has got to work on its ore but few men are needed. D. C. MacKaller, formerly at the Dolores, is manager. He has a large force of Americans under him and is milling 90 tons of ore per day, making an annual production of $750,000. They have a 750-hp. hydro-electric plant at San Francisco on Fuerte river, 7 miles from the mine. The dam and plant appear well built, and will probably stand the assaults of the river, which has been known to rise 50 ft. in 24 hr. However, a rise of this amount will probably result only in a temporary shut-down during high water. They are putting in an electric furnace to treat the concentrate, which is now shipped to San Francisco. Diamond-drills are also being provided to prospect the undeveloped territory underground. The rock is so hard that they use the chert in the tube-mills instead of pebbles, with satisfactory results. This chert also carries gold. Under the present management the Lluvia de Oro bids fair to regain the good name which it had under the Underwood management. George A. Schroter is consulting engineer.

In San Nicolas Arroya, which empties into the Fuerte at San Francisco, F. R. Barry has in the limestone an immense mine of lead ore carrying gold and silver, the lead mineral being largely cerussite, although in places galena appears. The vein is an enormous one of over a mile in length, and several hundred feet in width, but the erosion has cut out a large part. Still there are on his '3rd of April' claim several million tons, practically in sight, as one can quarry it from the lower side of the perpendicular cliffs, giving 600-ft. backs for 1000 ft. in length and 200 to 500 ft. in width. The ore assays $2 to $32 gold, and 14 to 180 oz. silver per ton. No assays were made for lead, though the ore contains a good percentage. As this is only 12 to 14 miles up-river from where the K. C. M. & O. (Stillwell) railroad will cross the Fuerte, it bids fair to help solve the smelting problem (scarcity of lead) on the west coast. It appears quite probably that most of the placers on the Fuerte river below San Francisco (and there are few above) had their source from this deposit. The placers contain little iron, but for miles below this arroya they all carry what the natives call 'copalia'—a variety of cerussite.

About ten miles south of the Lluvia, at El Oro, Jack Shedden, an old Leadville man, is doing some development on a gold property. He has some Michigan people associated with him. Not far from El Oro, at Pina Alta, one of the numerous companies controlled by Ed. Tuffts, with his brother Harry in charge, is doing a little work and expects soon to erect a mill. The Choix Consolidated, of Los Angeles, having over 30 prospects in the Choix district, is continuing its policy of not working. The company now only pays taxes, but from time to time promises to put in a copper smelter. A subsidiary company, with Mr. Hasford in charge, is doing a little work on the Las Platanos near Choix. Some 7 or 8 years ago Juan Mendoza worked this property and shipped ₱214,000 worth of 18% copper ore. Afterward I spent several thousand dollars in development on the same and then abandoned it. At Yecorato, Jim Donovan is doing a little work on one of Robert Duff's properties

under a bond. Mr. Duff has a number of promising gold prospects in a section which has produced considerable placer gold. Mr. Lezuardo, representing some Milwaukee people, has recently returned from the States to operate his dredge on Yecorato river, just above the town of that name. At Riolito, 12 miles southeast of Fuerte, in the agricultural section, there are two or three promising gold prospects. Donaciano Armenta has recently been doing some work on his Alta mine. There is a small belt of soft metamorphosed shale which appears to have numerous small veins, at a 45° dip. The erosion has left this free gold on the surface above the veins. I have never seen in Mexico a section more thoroughly worked than this, for placer gold. The work is so old no one knows when it was done, and still placer gold is found. At San Jose de Gareia, the Jesus Maria Anexas property, formerly owned by the Anglo Exploration Co., but now owned by Mexicans, under the efficient management of M. A. Newman, is making a new record for itself with an annual production of about half a million. Mr. Newman has completely overhauled everything, putting in tube-mills and a cyanide plant. All the power has been changed to electric, using wood at ₱10 per 2000 kg. The mine pumps, hoist, stamps, Huntington, and tube-mills, mechanical stirrers in tanks, and lights in mine are all run by electric power. He is now putting in an additional 150-hp. boiler for power for another tube-mill, and cyanide-vats to treat 50,000 tons of old $12 tailing. These have to be moved over 500 ft. by a belt, elevated 50 ft., and re-ground. Owing to using the old mill and the topography of the ground, the cyanide-vats had to be placed over 500 ft. from the mill on the higher ground and the tailing dumped there. Electrification was the most economical way to solve the power problem; it would probably cost $300,000 for hydro-electric power from the Sinaloa river, 12 miles away, and at present there is no demand for the surplus which would be generated. Everything runs smoothly, treating about 70 tons daily. The Rosarita mine, about one mile above the Jesus Maria, after a continuously profitable production for 25 years, is shut down. It had been in litigation for several years with other Mexican owners of adjoining ground who live in Mexico City—personal friends of Porfirio Diaz. They were finally given a judgment against the San Jose owners for ₱800,000, who gave up the mine rather than pay it. There are still on the property several undeveloped veins in a lime-shale formation which make as good a showing on the surface as those which have been worked. Just over the hill east on the Chihuahua side is a promising free-gold prospect, the Pasadena, in the limestone. It is a hematite iron-quartz much oxidized. It looks good, but is undeveloped. It is reported that Eugene Tahys is expected to commence work on the Silverlito, which is between San Jose and Rosarita mines, but on the south side of the creek. At Patagon, Norman Tracy is sticking to it, determined to make a mine out of his property. He has milled some good ore. The breast of the lower tunnel is now in very soft ground. Though using false-sets and driving the lagging, he has difficulty in holding the ground. Dr. Thornhill and Mr. York, formerly superintendent on Jesus Maria mine, are developing a very promising property north of Mocorito. They have done several hundred feet of work which shows two feet of the vein and assays $100 gold with silver and copper present, the latter being in the form of sulphides.

At Calabacillas things are running along nicely under the able management of A. J. Underwood, who recently returned from the States. The last few months their production has been above the average. F. O. Pellham, the efficient millman, is taking a much-needed rest of a couple of months. Mr. Jessup is taking his place. J. Webb, mine superintendent, is also taking a vacation, but A. H. P. Wynne, the assayer, bullion-melter, and cyanide man, continues to occupy his position. He has been on the mine practically since it was discovered eleven years ago. The mine has produced about three million and is only 500 ft. deep. It is on a contact vein between andesite and rhyolite, the ore being in the latter. It is a remarkable free-gold ore. They save 95 to 97% of its value. The Seiglo Nuevo, about 20 miles south of Calabacillas, is a promising gold prospect, with a record of over $20,000 gold production in about a year. It has recently been examined by several, but so far no deal consummated. Above Tohyana, on Sinaloa river, near La Platano, a new discovery during the past few months gives promise of adding another golden star to Chihuahua's mines. A friend who examined it says that for 40 ft. in width the vein runs $30 to $50 gold and appears to be extensive; that the vein, in fact, has been traced several miles and shows mineralization. There have been numerous locations made on it, even some overlapping others, but as no work can be done until title is issued, it is entirely undeveloped. Over at Trigo the Zeigler brothers have purchased from Sam Jones the 80,000-ton dump of tailing made by the Anglo Exploration Co., and are preparing to treat it by re-grinding and cyanide. They intend to use an old Brückner roaster as a tube-mill. All through the mining districts with which I am familiar, practically all for the past two months have been busy remonumenting their claims, according to the new mining law. Especially is this true of the foreigners. They will all comply with it, but there is a disposition in places on the part of some native owners not to comply with it; it is proving to be quite expensive in many instances, owing to the topography of the ground, but if properly done it is permanent and a good thing for all. If they had been obliged to place upon each monument in figures the number of the title as well as the number of the monument—for instance, $\frac{4598}{3}$—it would facilitate matters very much, especially in congested districts.

Mineral-wool is glassy slag blown by compressed air into thousands of hair-like shreds. It is used as a non-conductor of heat, for fireproofing and similar purposes.

Pay-Streaks at Nome

By T. M. Gibson

*If nuggets exist anywhere in the third beach they will be found in the zone, marked by cannon-ball boulders, just below the beach plane proper. These boulders have done the tube-mill work in the surf, each being driven up and drawn back by the waves until it is worn out, or by some chance is drawn below the line of action of the breakers and finds a resting place in this row of boulders at the foot of the plane.

The beach plane rises about one foot in ten from the lower rim to near the middle, and then one foot in eight or less to the upper rim. The richest zone is invariably at the foot of this last slope. It is here that single pans could be picked up on the Portland, the Three Star, or May Fraction that would yield $500 or more. This rich zone was generally less than 25 ft. wide, and 90% of the gold was within 3 in. of the bedrock. There were places where one could pick up a dollar's worth of gold between his thumb and forefinger, and no single piece would weigh more than a tenth of a cent. More than $330,000 was taken from a spot in the May Fraction 100 ft. long and of an average width of 15 ft. Ninety per cent of this was in the bottom three inches, making a pay-streak worth over $21,000 per cubic yard. This rich zone on the Three Star Fraction was worth $2500 per linear foot of pay-streak, and parts of the Portland claim were worth $3000 per linear foot. These rich lenses were usually from 100 to 200 ft. long, and then would come a leaner zone and sometimes a blank. Of the two miles from the Portland claim to Discovery, Dry creek, about 3500 ft. was blank, 1200 ft. is still unworked, and the remaining 5860 ft. has averaged nearly $1700 per linear foot, and it is not yet exhausted, though the future output from drift-mining will not materially increase these figures. Most of the claims which carried these immensely rich lenses had in addition a much larger body of good pay-gravel. From the lower rim to the upper rim there would be a continuous body of gravel about 3 ft. thick that paid a handsome profit over costs of mining. It must not be understood that a so-called 'blank' is an area where the beach has been removed by subsequent erosion. The beach material is there, but the gold is lacking. This is a subject upon which there has been much speculation, and many theories advanced, some of which fit the facts of every case. The configuration of the shore-line undoubtedly had much to do with the richness or leanness of the deposit. In the case of the Mojave and O. K. claims, adjoining the east end of the Portland and the west end of the rich Four Corner Fraction, a low cliff or perpendicular wall of bedrock, rising abruptly along the shore, confined the shore-line, maintained a considerable depth of water, and effectually prevented the milling action of the surf which is so favored by a sloping shore. These claims lie in the most favored locality of the entire beach-line, yet they were 'blanks.' Again, a very low shore-line has an equally disastrous effect. The variations in the water-level due to the tides and to off-shore and on-shore winds, carries the surf-line over too great a surface area to leave a well defined line of concentration. This was exhibited to some extent in claim No. 4 Bourbon, and very notably between Cunningham and Hastings creeks. In this latter locality the beach-line is merely a low sand-bar which separated the open sea from a mile or more of lagoons and salt-water marshes lying between it and the foothills. This bar is the barrier eventually formed between Cape Nome and Army Peak, by the currents of the sea, and which cut off the shallow bay that had formerly reached inland to the foothills. The gold in this part of the beach is more finely divided than in that to the west of Nome river. It is spread over a wider area and is of such low tenor as to scarcely pay the expense of drift-mining. The old channels that drained the uplands and emptied directly at this old shore-line were an important factor, and probably the one of greatest importance, in determining local enrichments along the beach-line. The deltas of such old channels are easily recognized and several have been found during the progress of the work along the beach. The most important of these is the old channel of Anvil creek which poured its rich gold-bearing gravels into that part of the shore-line now covered by the famous Portland claim. I shall discuss this one at some length further on, as it played an important part in the enrichment of all the beaches down to the present one. Another old channel emptied in the vicinity of the east end of the Bessie claim and west end of the very rich May Fraction. This was a Dry creek channel and has subsequently been traced to the foot of the upland valley of Dry creek, a distance of approximately one mile. It seems to have had many meanders and to have shifted its bed frequently, leaving the gold-bearing gravel over an area of considerable width with rich concentrations in spots.

Another channel emptied a short distance east of Irene creek. This was a stream of considerable size and was probably the outlet of Osborne creek, which now flows westerly along the north flank of Army Peak and empties into Nome river. No effort has so far been made to follow this old channel toward its source, but the fact that it furnished gold for a rich beach deposit about its mouth, together with the well known gold-bearing character of Osborne creek gravels, and the strong probability that this was once the lower Osborne valley, make the area between this old delta and St. Michaels gulch, a southerly tributary of Osborne creek, a promising field in which to prospect. This covers a stretch of about three miles that is as yet unprospected. The only important deposits so far discovered west of Snake river lie at the mouth of an old channel which emptied into the beach a short distance east of Sunset creek, and this, no doubt, accounts for the local enrichment at that place. This

*Continued from page 424.

old channel is also yet unprospected, but will probably prove upon investigation to be a valuable deposit. These are the principal old channels that fed the third beach, but there are several of smaller size, each of which had a marked effect upon the enrichment of the beach-deposit about its mouth. Although generally rusty in appearance, the beach gravels are nowhere cemented (except by ice in the frozen belts), though there are a few small areas of bedrock where the slabby phyllites after having been shattered and loosened enough to allow gold and sediment to work down to a depth of two feet or more into the seams, were then cemented by iron oxide so that the gold adheres firmly to the broken bits of cemented material. This beach carries but little pyrite or other sulphides in the upper plane, but contains about 10% garnet sand and 1% magnetite and ilmenite with small quantities of limonite, hematite, and scheelite. These are distributed in the lower four or five feet of the deposit with an increasing percentage as bedrock is approached. The whole body of beach material is stratified into layers of varying degrees of coarseness, each layer being from an inch or less to a foot or more in thickness. In the lower plane or 'Slough-Over' the heavy minerals are not so well assorted into the bottom layers, and they occur more sparingly. Pyrite and arsenopyrite are usually present in the shattered surface of bedrock.

The distribution of permanent frost along this beach-line is peculiar, and no satisfactory explanation of its occurrence has yet been advanced. The entire deposit is frozen from surface to bedrock over approximately 75% of its length. The remaining 25%, with the exception of three or four narrow strips, is thawed only along the upper plane. On the seaward side of this plane both the 'Slough-Over' pay-streak and the overburden are permanently frozen. The frost wall rises quite abruptly from bedrock to surface even where the overburden is one hundred or more feet thick. This condition has been very advantageous to the work in the thawed areas, as it enabled the operators to sink shafts, make stations, and install pumps before having to cope with the water. Having everything in readiness a drift was driven to the thawed ground and the water allowed to flow down the slope to the pumps. The handling of the water in the thawed ground has never been a serious problem. The heaviest flow is in the neighborhood of No. 2. Saturday Creek, and the west end of the Bessie claim, where one hundred acres or more of thawed ground lie along the beach and to the northward. The flow here was approximately 500 gallons per minute in the Bessie workings. After a few weeks of continuous pumping in any given area, the flow begins to decrease, and at the end of three or four months is only about half what it was at first. This water is merely reservoired within frozen walls, with an overflow at the lowest surface point, and continued pumping would exhaust it down to mere seepage, the equivalent of the overflow. The thawed areas are of irregular shape, extending to the northward from a few hundred feet to a mile or more, but their south lines are coincident with the south rim of the upper beach plane; and though they may extend from 1200 to 3000 feet along this course, they do not deviate more than a few feet from this line. There are three notable exceptions to this rule, where in the beds of Wonder, Dry, and Newton creeks strips from 100 to 300 ft. wide are thawed considerable distances down-stream. Since the overflow from the thawed areas continues during the winter, it is probable that the water is derived from springs which have their source in the foothills and which reach the surface of bedrock at or near the base of the hills, with the temperature raised considerably above the freezing point and, consequently, are slowly thawing what was once a solidly frozen area. This may be the correct theory as to the origin of these thawed areas, but why they advance their southerly lines so evenly, or why several widely separated areas of different surficial extent should occupy the same relative position along their southerly boundaries is not so apparent.

Cross-Section, Beaches at Nome.

A matter of greater importance to the miner is the fact that the pay-streak in the thawed areas is not nearly so rich as it is in the frozen areas. This rule is without any exception, and it is so marked in several instances as to leave little room to doubt that it is something more than a mere coincidence. In the Discovery claim on Dry creek a strip of thawed ground about 250 ft. wide separated two frozen belts of pay-streak. Approaching from the west through the Ingleside and Tidal Wave claims, the pay-streak averaged about $2000 per linear foot on the upper plane. This average value continued into Discovery claim to the edge of the thawed ground and within the next twenty feet dropped to $500 or less per foot, and within 100 ft. dropped to less than $200, and did not improve until the frost was reached on the east side of the thawed strip. Here it was again worth about $1500 per

linear foot. In a like condition on the Bear Cub claim, the grab-samples dropped from 40 to 50 cents per pan in the frozen ground to 8 cents per pan in the thawed ground. In the Bessie claim the frozen ground was worth $2000 per linear foot and the thawed ground $300 or less. The Bessie thawed ground is on the east side of thawed strip about 1200 ft. long, and, although the greater part of this is, as yet, unworked, it has been extensively drilled and no rich ground encountered. Immediately to the west of this thawed area the Solo claim and westerly edge of No. 2 Saturday Creek were of the usual high grade found in the frozen ground. From a point about midway between Newton and Otter creeks, easterly for 3000 ft., is a continuous belt of thawed beach, and this stretch averaged less than $100 per linear foot, and no part of it exceeded $300 per linear foot; yet, adjoining this belt on the west, the Bon Voyage claim, in frozen ground, averaged about $700 per linear foot, and No. 9 Otter creek, adjoining on the east, about $400 per foot in 250 ft. of frozen ground, with the usual low-grade pay in its thawed ground. These facts, I think, leave no room to doubt the rule, but the reason for these differences in value between the frozen and thawed ground along this paystreak has not yet been found.

The Monroeville beach lies about three-fourths of a mile south of the third beach, and has been traced from a point near Little creek to Holyoke creek. It is approximately parallel with the third beach. This pay-streak, although having an east-west trend and lying upon true bedrock, sloping gently seaward, is yet so different from all the other beach-deposits as to have raised doubts in the minds of many miners as to whether it is a beach-deposit. While carrying much surf-worn material, the deposit is for the most part of very much coarser gravel and is without that definite stratification by which the other beaches are so readily recognized. Further than this, the gold is very much coarser than in the other beach pay-streaks, and is almost wholly in the shattered surface of bedrock. More than half the gold mined from the Union claim, which lies near the centre of the explored area of this pay-streak, is in nuggets, ranging in value from 25 cents to two or three dollars, with a few up to $30 and $40. Both east and west from this central portion, the average coarseness is diminished until at the extremities of the worked area it is little, if any, coarser than average beach gold. It differs from the other beaches, also, in having but little 'ruby sand' and no well defined layers of this material. There is a small quantity of 'black sand', but the most abundant heavy minerals are the sulphides, pyrite, and arsenopyrite. These latter occur in larger quantities than in any of the other beach deposits. This pay-streak is from 300 to 500 ft. wide, and its slope to seaward is only about 1%. About one foot of gravel lying on bedrock and from two to three feet of the shattered surface of bedrock are taken for the pay-streak. It is too low grade for profitable winter driving operations and is mined chiefly in the summer-time, when the material can be dumped into hoppers and sluiced as mined, thus saving the expense of rehandling from dumps. Its output to the present time has been about $400,000. There is still a large bedrock area unworked. This beach is 33 ft. above sea-level, and is overlain by from 50 to 55 ft. of muck, sand, and gravel, all of which is permanently frozen. It seems certain that this deposit owes its east-west distribution to surf agency, but it is probable that the shore-line stood at this level only a comparatively short time, and derived its gold chiefly from the rich gold-bearing gravels of the old channel of Anvil creek which had formerly made its way to the more southerly shore-lines through the area now covered by the Union mine, and probably had its mouth in this vicinity when the shore-line stood at this level.

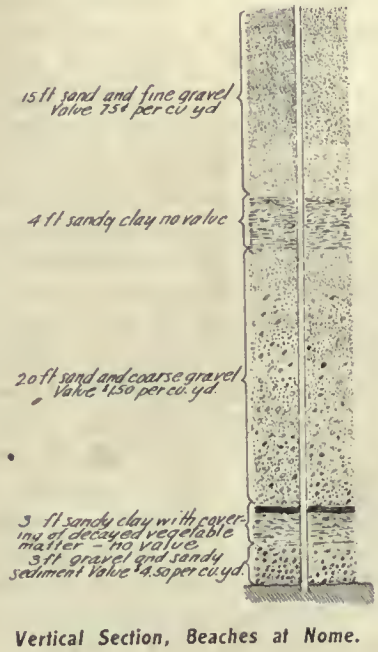
This old channel has undoubtedly been a very important factor in the enrichment of all the beaches in the zone lying southerly from the upland valley of Anvil creek. It was discovered by J. C. Brown in the fall of 1904, in his claim, No. 1 Below Discovery, on Little creek. Mr. Brown has often been given credit for the discovery of the famous third beach, but while his discovery of very rich pay was the cause of energetic prospecting in his immediate neighborhood, and this, soon after, led to the discovery by Johnson & Peterson, of the third beach, in the Portland claim, as a matter of fact, Brown's claim did not contain the third-beach pay-streak at all, but covered this old channel of Anvil creek which emptied into the sea a short distance to the south and east of his boundaries. This channel was well incised into the bedrock, and has subsequently been followed and mined in a northerly direction to its junction with the present bed of Anvil creek at Discovery claim, a distance of three-fourths of a mile. The rims are from 4 or 5 up to 10 or 12 ft. above the lowest part of the bed, and the pay-gravel not only entirely fills this trench, but overflows both to the east and west of the channel rims. The richest gravel is in the lowest part of the channel. In that part of Mr. Brown's claim facing the old seashore, the gravel bed has been worked to a width of 500 or 600 ft., though the channel proper is probably not more than 150 ft. in width. The total depth of the gravel is from 20 to 25 ft., and this is overlain by from 12 to 15 ft. of ice, bluish and black muck, and tundra vegetation. The entire deposit is permanently frozen.

The gravel within the channel rims is coarse creek-wash, consisting chiefly of quartz, schist, and limestone shingled by swift, southerly flowing currents. The overlying gravel is of cross-bedded delta character, the bedding usually standing at high angles. This material is of very similar character to the underlying channel gravel, but occasionally has rounded, surf-worn pebbles and sand interbedded with it. The best pay was on and near bedrock, but it was sometimes found following an inclined bed, and would be rich up to fifteen or more feet above bedrock. Mr. Brown mined and sluiced $40,000 in two weeks time, working three men, just at the close of the season of 1904, and by the end

of 1906 is said to have made himself a millionaire from the output of this claim. The gold was coarse and did not differ materially in physical character or fineness from that which was mined from the present bed of Anvil creek. Pieces worth from 10 cents to $2 were quite common, and many nuggets worth up to $30 and $40 were found. The bedrock is partly slaty, calcareous schist—or phyllite—and partly bluish crystalline limestone. The limestone lies to the east and northeast, making the southwest flank of Anvil mountain, and the schist to the west and southwest. The channel appears to have followed more or less closely along the contact, though sometimes entirely in the limestone and again entirely in the schist. As is the case with Anvil creek, some of the gold shows very little wear and the coarser pieces frequently have calcite and quartz, and sometimes scheelite crystals attached to them.

The accessory minerals which are most abundant are limonite, which is often found in nodules as large as a hen's egg, hematite, garnet, pyrite, scheelite, magnetite, and ilmenite, their relative abundance being in the order named. A pan of gravel taken from the bedrock, with boulders and coarse material excluded, will yield a half-pint measure full of these heavy minerals. The gravel is generally rusty in appearance, and occasionally a spot is more or less firmly cemented with iron oxide, though as a rule it is loose and free after it is thawed. Both in the limestone and the schists are many small mineralized veins and lenses, and these have probably contributed at least a part of the gold that made this area so rich, and by their reconcentration in the surf made the beach sand of the Portland claim, near bedrock, resemble a tray of coin at a bank teller's window. The fact that this ancient channel is intrenched into bedrock below the rims of the third beach offers indisputable evidence that it once emptied farther south when the seashore was lower than the third-beach level, and there is some reason to believe that it may have once emptied farther south and at a lower level than the present beach.

After exhaustive research and careful consideration of all the evidence by members of the Geological Survey, the conclusion has been reached that this portion of Seward Peninsula—that is, the area in the immediate vicinity of Nome—has, within comparatively recent times, geologically speaking, been uplifted, relatively to the sea, approximately 800 ft. In other words, what is now the 800-ft. contour on the hills adjacent to Nome was formerly at or near sea-level. The discovery three years ago of the submarine beach, which is 19 ft. below the present sea-level, is evidence that the uplift was greater by at least this amount, and recent prospecting with a Keystone churn-drill, offshore, about a mile west of the mouth of Snake river, has revealed what appears to be another beach or shoreline concentration at a depth of 45 ft. below sea-level. It is, therefore, evident that the uplift was greater than 800 ft., and we simply lose ourselves in speculation in attempting to fix a limit. It is possible, since Bering Sea is only 1200 to 1500 ft. in depth, that there was dry land connection with Asia, and the mighty mammoth, the remains of which are found buried in the frozen silts of the river valleys of both Alaska and Siberia, once roamed at his pleasure from the valleys of the Yukon, Koyukuk, and Colville to the valleys of the Anadir, Kolima, and Lena. The similarity of the flora also suggests that at some time in its geological history there may have been dry land connection between these countries. Whatever may have been the height to which these shores were elevated, it is certain that a subsidence followed and the sea again invaded the land. This subsidence was of an intermittent character, and various stops were made, each of sufficient duration to make a well-washed shore-line, and the tireless roll of the surf, dashing the rounded quartz pebbles and boulders up and down the gently inclined plane of the shore,



Vertical Section, Beaches at Nome.

accomplished an amount of trituration and concentration which makes man's efforts at milling operations appear puny indeed, in comparison.

Alfred H. Brooks, of the Geological Survey, who very early and with acute prophetic vision foresaw the probable presence of these ancient beaches in the coastal plain, seemed to labor under the impression that they were formed successively from the highest to the lowest or present beach, each representing a period of stability in the general uplift that took place in Quaternary time. He says, in his report of 1900, 'A Reconnaissance of the Cape Nome and Adjacent Goldfields of Seward Peninsula, Alaska', pages 80 and 81: "It has already been shown that the region has been gradually elevated during recent geological time. The coastal plain terraces, like the high benches already described, are made up of material that was deposited along the margin of the shore while the land stood at lower elevation relative to the sea than it does now. The successive benches mark a series of interruptions in the uplift, when the land stood at a constant elevation long enough to permit the accumulation of the material of which the terraces are

formed." And again, on page 90 of the same report, he says: "A question of interest is whether there may not be old beach placers in this region similar to those that are found in Oregon. It has been assumed that this part of the Seward Peninsula has, in comparatively recent times, been elevated to a height varying from 600 to 1400 feet. Attention has been drawn to benches which are believed to represent former shore-lines. It is a logical conclusion that during this period of uplift similar beach placers have been formed in the region, and a search for them should be a fruitful field of investigation. It has been suggested elsewhere that some of the escarpments in the coastal plain may mark former shore lines." In Bulletin No. 379, a report on progress of investigations in 1908, Philip S. Smith, of the Geological Survey, says, on pages 273 and 274: "About a dozen species of fossils collected from the submarine beach at this place (near Nome) by E. M. Kindle and the writer were submitted to W. H. Dall for determination. From their resemblance to fossils whose geologic positions have been determined, he stated that these forms mark, undoubtedly, the oldest horizon that has been found in the unconsolidated deposits of the Nome coastal plain. This coincides closely with the decision that had been reached by the writer on entirely independent grounds, namely, the relation of the gravels containing the fossils to the overlying deposits and the greater amount of decomposition that had affected the shells. No final statement can as yet be made regarding the precise geologic age of the fossils from the submarine beach, but there seems little room to question that they are at least as old as the Pliocene." Again on pages 277 and 278, he says: "From the present evidence it would seem that the earliest event recorded definitely, in the history of the region, is the formation of the 'outer submarine beach.' What the condition of the region was, prior to this incident, is not known, but it is probable that older coastal-plain deposits had been formed and were eroded by the waves to form this beach. After the outer beach had progressed to a certain stage, gradual depression with respect to the sea brought the shore-line at the level of the 'inner submarine beach.' The amount of this depression must have been about 14 ft. Still later, further subsidence of about 42 ft. brought sea-level to the elevation of the intermediate beach. The movement continued and the land sank with respect to the sea about 56 ft., so that the shore-line was on the level of the third beach. While each of the beaches was being formed by the sea, deposition was taking place on the sea floor, and sands and gravels brought down by the rivers and worn from the cliffs by the waves were covering the earlier beaches, thus producing a surface such as the sea floor of the present day might show, if it could be examined. After the shore-line had taken a position landward of the third beach, a change in the progressive depression of the land took place and uplift began. The result of the uplift was to cause more and more land to emerge from beneath the sea. The uplift seems to have gone on at first without any interruption, for there are no signs of long halts and the accompanying formation of beaches on the surface of the coastal plain. At length, however, when the shore-line was some distance to the south of the 'second beach' a period of relative stability ensued, and the sea gradually cut back into the coastal-plain gravels until a cliff, in places nearly 75 ft. high, towered above the beach. This feature can be more plainly seen in the vicinity of Rocker and Martin gulches, a little east of Nome. When this stage of cutting had been reached, an uplift of about 38 ft. brought the shore-line to a short distance seaward of its present position, and then in a period of stability the sea renewed its cutting on the shore and formed the low cliff which rises from the present beach." This is the more rational interpretation of the cycle of changes that have taken place in the geological history of the Nome coastal plain, and, if correct, will justify my statement that the old channel of Anvil creek probably once emptied farther south and at a lower level than the present beach. It was this old channel which brought the rich gold-bearing gravels southward from the Anvil hills, and their presence is evident in each successive shore-line from the third beach at Little creek to the present beach just west of the mouth of Snake river. It is on a line drawn between these points that all the beaches are richest. Moreover, between the shore-lines along this course, where the bedrock is of a slabby nature and makes good riffles for holding gold, many mines have been and are being worked.

While the bedrock floor of the coastal plain is slightly uneven in character, it is, broadly speaking, a gently-sloping plane from the foothills to the sea, along this line, and it is probable that this ancient stream as it made its way to the southward, following the receding shore-line, during the first uplift, played back and forth over a zone a half-mile or more in east and west extension, and thus left here and there the locally rich areas which mining operations have demonstrated to exist within this zone. It does not appear to have left a deeply incised channel south of the third beach, but this may be due in part to frequent changes of its course, after entering upon the open plain and in part to the cutting away of the channel rims by the waves, as the sea again invaded the land. There are, indeed, certain depressions having a north-south trend and low rims along the east side of Center creek for the last half-mile or so of its length, and even extending across Snake river to and beyond the submarine beach, where the bedrock has been carved away a few feet below the beach-level, and where a rim dipping to the eastward led Philip S. Smith to speculate on its probable cause. His conclusion was, that it was probably due to warping, but he admitted that his evidence was insufficient to form a definite conclusion. While these channel remnants have not been definitely connected with the northerly extension of the Anvil channel, they are best accounted for as a part of this old system. When the limit of the first elevation of the coastal

plain was finally reached, and subsidence began, this channel poured its rich gold-bearing gravels into each successive beach, during the time it was forming, and the grinding and sorting action of the waves milled and re-concentrated the material thus brought in. As the subsidence carried the shore-line to the landward of the third beach, the stream not only completely filled the rims of its old bed with gravel, but spread out to form a wide delta, 20 to 25 ft. thick, and being here near the upland valley which supplied the gold, made the rich placers worked by J. C. Brown and others, to which I have already referred. This old channel, no doubt, enriched the fourth beach to payable placers at the foot of the upland valley, but as subsequent erosion has carried away all traces of this beach in that vicinity, its gold has been scattered over the bed of the later stream as it once more followed a receding shore-line to the south.

BALATA

Balata is a variety of rubber which is used in the manufacture of belting and for the insulation of wires. The tapping of the balata trees is done with a cutlass, incisions being made not more than 1½ in. wide, about 10 in. apart, in a 'feather-stich' pattern up the trunks of the trees. The sap runs zigzag from cut to cut into a calabash at the base of the tree. The sap is collected from the calabashes into gourds and then it is taken to the camp, where it is poured into shallow trays that hold from 5 to 30 gal. The sap coagulates in these trays and the balata is taken off in sheets, dried, and despatched to town for transhipment. The laborers are paid by results, according to the amount of balata collected.

The following table shows the exports, in five-year periods, of balata from British Guiana since 1890.

Period.	Total for 5 years. Lb.	Average export per year. Lb.	Average value per year.
1890-1894	995,515	199,103	$73,400
1895-1899	1,682,265	336,453	100,600
1900-1909	2,386,655	477,331	162,750
1905-1909	3,278,683	655,737	353,350

Magnetic separation is based upon the fact that different mineral species possess different ratios of a physical characteristic called magnetic permeability; which means the ratio of their conductivity for magnetic lines of force compared to the conductivity of air. The determination of the exact permeability of minerals is exceedingly difficult, on account of the chemical differences in specimens from different localities; as well as the difficulty in securing sufficiently large specimens of the pure minerals. Investigators, however, have arrived at close approximations. It is found that magnetite is of sufficient permeability to ensure its easy separation from quartz, feldspar, apatite, pyrite, and other minerals, and that the permeability of pyrrhotite and ilmenite approaches the permeability of magnetite so closely that their separation from the latter is much more difficult.

Timber Treatment Plant at Rocker, Montana

Wood preservation, while important in its broad national aspect, is of direct personal importance to every user of timber which is exposed to decay or insect attack; for by lessening the cost of maintaining his fences, his mine timber, his telephone line, or his track, it means a direct saving in dollars and cents. The following is a description of a wood-preserving plant built by the Anaconda Copper Mining Co. in co-operation with the United States Department of Agriculture, Forest Service, at Rocker, near Butte, Montana.

The treating cylinder, 6 ft. diam. and 43 ft. long, is built to withstand a working pressure of 100 lb., and has a capacity of 350 cu. ft. or 6360 ft. board measure per run. It was planned to treat all the ties and bridge stringers for the Butte, Anaconda & Pacific railway, shaft-sets, and timber in the permanent openings of the company's mining properties at Butte and vicinity. Steam, electric power, etc., are furnished from the boiler and engine room of the old framing mill, where all 'stope' timber is framed, some 400 ft. distant. All the timber is shipped in by rail and unloaded in the storage yards, from which it is conveyed to the treating plant by means of small train cylinder cars run on 24-in. gauge tracks. After treatment the timber is piled on the loading platform ready for shipment. A tank for the butt treatment of poles is placed near the treating plant. Lodgepole pine poles given a butt treatment with creosote will last 18 to 22 years, as compared with 8 to 13 years for untreated cedar.

The following table shows approximately the relative cost of untreated cedar and treated lodgepole pine poles f.o.b. Butte. It is seen that in every case the treated lodgepole pine will cost less than the untreated cedar:

Length.	Top Diameter.	Cost: Untreated Cedar.	Cost: Treated Pine.
25	6	2.10	1.85
25	7	2.45	2.16
30	6	2.65	2.37
30	7	3.20	2.80
35	6	3.85	3.00
35	7	4.75	3.60

As an instance showing the relative saving by using treated timber, the following case is cited:

The cost of one complete set of untreated timber erected in a main drift of cross-cut is	$20.77
The cost of a similar treated set	28.02
Estimated length of life of the untreated timber	6 years
Estimated length of life of the treated timber	20 years

Figuring 5% compound interest, the annual charge for the untreated set would be $4.09, as compared to $2.38 for the treated, thereby an annual saving of $1.71 per set is obtained by using treated timber. However, in considering the practice of wood preservation the initial cost of the timber should not only be considered, but also the labor cost of replacing decayed material and the gradual increase in price of all kinds of lumber, poles, and ties.

Del Norte County Geology

By Oscar H. Hershey

Owners of mines in Del Norte county, California, will doubtless be interested in a geological map of that region. The map printed herewith is based on a rapid reconnaissance made in 1907, and, while not accurate in detail, shows the general distribution of the formations. The soft sandstones and silts of the late Tertiary formation underlying the 'Cresecnt City lowland' contain some thin lignite layers. The Franciscan sandstone and shale belt (perhaps including some Knoxville shale near the Oregon line) is not mineralized. Prospects are widely scattered in the great belt of serpentine and meta-gabbro that crosses the county from north to south. The Ora Anna is a gold-quartz vein in meta-gabbro. The Alta is the principal old mine of the Low Divide copper district. The country rock is serpentine. The Cleopatra is also a copper mine in serpentine. The Table Mountain is an old copper mine in serpentine. Many copper prospects are present in the belt near the Middle Fork of Smith river.

In the vicinity of Patricks creek there is a group of base gold-quartz veins in early Paleozoic igneous rock. The Monumental, working bodies of auriferous arsenopyrite impregnating altered basic rock, is the principal old mine in Del Norte county. Next in traversing the county from north to south is crossed an irregular belt of Galice dark gray and black slates and crushed sandstones, resting on a volcanic series and intruded by the serpentine-meta-gabbro series and by granitic rocks. The Weitchpec schists are mainly highly metamorphosed portions of the Galice formation. The Galice has been studied in Oregon by J. S. Diller of the U. S. Geological Survey, and shown to be of the same age as the Mariposa slates that follow the Mother Lode in the Sierra Nevada region. However, in Del Norte county the belt does not contain any important prospects so far as I know.

It is evident that the majority of prospects and mines in Del Norte county are in the serpentine and meta-gabbro areas, though the Paleozoic rocks of the Patricks creek district are also favorable. The Galice and Franciscan areas are practically barren.

Geological Map, Del Norte County, California.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A B C of Empire Drilling

The Editor:

Sir—In your issue of February 25, I note a letter by Fred J. Siegel, referring to the use of the Empire hand-drill. His conclusion that not rotating the casing and not starting the pipe plumb were the causes of its not remaining vertical, however, are wrong. The casing was rotated continuously during the operations and the casings were always tested by levels to make sure they were exactly plumb. The reason, as stated before, was that the gravel was loosely packed, and when a boulder was struck slantingly, the shoe would work around the side, thus throwing the whole pipe out of plumb.

Great Cobar Mine

The Editor:

Sir—I have had sent to me from Australia your paper of November 19, 1910. The part of the report you print to which I object is that a casual reader might assume that I was responsible for the plant that failed. Neither myself nor any of my officers had seen a plan of the furnace plant until some weeks after a considerable portion of it had arrived from America. During the years you say that the Great Cobar mine yielded handsome profits for the local owners I might inform you that I was the general manager, in fact was mine manager at Cobar and then general manager for all the Great Cobar Syndicate's properties for about five years before Great Cobar Ltd. appeared on the scene, and was then general manager for that company for two and a half years, and made for them £190,000 profit, the only profit the latter company has ever made.

Mining in the Ketchikan District, Alaska, in 1910

The Editor:

Sir—My attention has been called to an omission in the Press Bulletin which summarizes the mining industry of Alaska for the year 1910, issued by the United States Geological Survey, December 31, 1910. In this publication no reference was made to the fact that in September operations had been renewed at the Rush and Brown copper mine, located near Karta bay, Prince of Wales island. As the bulletin purported to enumerate all the properties in the Ketchikan district upon which any important work had been done during the year, the operations at the Rush and Brown mine should have been referred to. The only excuse that I can plead is that the Press Bulletin was prepared in considerable haste and that the omission was simply an oversight. There were probably other mining operations in Alaska of equal magnitude which did not receive mention, but in this case the omission was the less excusable because you had already recorded the fact of the renewal of operations at the Rush and Brown mine in your issue of October 29, 1910, page 588. It is my purpose to have the annual summary of the mining developments in Alaska, published by the U. S. Geological Survey, present a complete account of the conditions of the mining industry throughout the Territory. I shall be glad if mine operators and engineers will inform me of any omissions or errors which occur in these publications. The Press Bulletin issued about the first of January of each year is simply a preliminary statement to be amplified and in some cases, I regret to state, corrected by the more complete report published some months later.

Tank Versus Vat

The Editor:

Sir—For a long time past I have noticed that you consistently speak of 'cyanide vats' in describing cyanide plants. Not remembering ever having heard the word 'vat' used in and about cyanide plants, except by one foreigner, who puzzled me for some time as to what he was referring, I went to some pains to look up the matter and found that on page 40 of 'A Guide to Technical Writing,' the distinction is made that a tank is a receptacle for holding a fluid, while a vat is a receptacle for carrying on any process, such as leaching for example. In other words, a tank is a tank if you put a liquid in it and leave it there, but if you carry on any operation in it, it is a vat. The dictionaries confirm this distinction, but all the same I want to hand in a minority report which I think the great majority of engineers will endorse. When I went to High School the teacher used to tell me in rhetoric class that "use is the law of language," and unless my ears have deceived me the men who are doing cyanide work do not talk about 'vats.' What difference does it make if technically it is a vat—a cyanide tank is not exactly like anything that existed before cyanide practice began, and if cyanide men had chosen to call it a papoose, who is there to say them nay?

EVE—That is a park.

ADAM—Why do you call it a park?

EVE—Because it looks like a park!—'Extracts from Adam's Diary.'

Not long ago the editor of *The Engineering and Mining Journal* tried to make us believe that a smelter ought to be called a smeltery, but no one ever stopped long enough even to laugh at him. It riles me, Mr. Editor, to write you what I consider an interesting and valuable description of my cyanide tanks and then have you put me down in print as using vats. They may use vats in a brewery and a dye works, but I call for a show of hands from the men who are doing cyanide work. Do we use vats or tanks?

Mistakes of the Prospector

The Editor:

Sir—Under the above heading I wish to present a series of facts that although minor in detail are far reaching in effect, and tend to wreak incalculable injury to mining in general, and especially to prospecting. We know, that is, we all should know, that capital can not and will not invest great amounts of money on surface indications unless they are exceptionally favorable. What is the average prospect but a surface indication, and how many prospectors are financially and physically able to sink deep shafts, drive drifts, and block out ore in order to demand a good price? Very few indeed, and these grow old in their endeavor, and do not realize that a much smaller sum would have been of more benefit to them in younger days, if judiciously invested, than a large one now. We have here a number of men who have passed the three-score mile-post and have worked their claims for a number of years. They had several opportunities to sell, but no, they have fixed prices, as high as the ladder which Jacob saw in his vision, and cash at that, and now they are like X. Beidler's dogs, waiting. These dogs, when they had driven a woodchuck to his hole, would squat on their haunches around the hole, awaiting his coming out. So finally the Government took a turn one day and bundled the whole tribe of Indians on the train. When it entered the Big Horn tunnel the dogs squatted on their haunches and waited its return, but it never came, and today—their bones are bleaching on the plains. The prospectors should consider that if anybody paid them their price, say one-quarter cash, and the actual price should be $60,000, the buyer would have to expend an equal sum, if not more, before he would realize a cent out of the venture.

Another matter of serious import is, misrepresentation and overestimation of values. A case happened here some time ago where a prospector went to Los Angeles and while there exhibited specimens of unusual value which he had pilfered from a neighboring property. Several people became interested and sent two men out to examine. They could not find a trace of the ore which had been exhibited, on the ground, but found out from where it came. Common sense should tell a man that such action is foolish, dishonest, that it is certain to be found out, and will not only hurt him but the whole district as well. Next comes the fellow with imagination, as, for instance, a certain man stated a year ago that he had exactly a second Witwatersrand, quartzites, schist, reef, and all (but the trouble is that the conglomerate is lacking, and a few other things too numerous to mention). Next he electrified the country by maintaining that he was on the North Star lode, which is about 35 miles distant, in Tertiary eruptives, while his claims are in pre-Cambrian schists. I presume the next thing we shall hear is that the lode has cut the Huronian and Laurentian and is rooting around in the barysphere, looking for a point of least resistance. People should treat such effusions for what they are worth, and this case with a covert sneer. In conclusion, I will state that the worst and most pernicious evil is the knocker, and he is found among all classes, from the hotel man who meets you at the door with a hearty smile upon his face, and as soon as your errand is stated and inquiries made, exclaims, "Ach Gott! it's nothing there!"—to the fellow who has been sent to look up some promising properties, and who initiates his entrance into the community by a grand old debauch, thus wasting the money trusting friends have furnished him, and then reports adversely, to cover up his shortcomings. Lastly comes the prospector who with envious eye looks upon his neighbor's progress, and the one who holds his claims by the easy method of pencil and paper, re-locating every 90 days.

Much more could be written of the shortcomings of the pioneers of mining, but I believe that I have stated the worst features, and hope the near future may bring better results. To suggest a remedy is unnecessary, for it is within the domain of common sense and its construction devolves on the one most interested.

Quartzsite, Arizona, February 17.

Weight and Volume of Ore

The Editor:

Sir—The method used by Charles P. Brooks for obtaining the specific gravity of ore was given in your issue of February 18, in an interesting article on the weight and volume of ore. His method consists of the obtaining of the volume of an unknown weight of ore by burying it in a box of wheat or grain, leveling the grain off even with the top of the box, then removing the ore and getting its volume by measuring the volume of the box from its top to the top of the grain. I have used practically the same method on a smaller scale, but substituted water for the grain. I had under consideration the specific gravity of galena ore with a quartzite gangue and containing blende and pyrite. The ore was hard and practically impervious.

I made a water-tight wooden box, whose inside dimensions were four by four by fourteen inches. This box was filled to a depth of about seven inches with water and the distance from the top of the box to the surface of the water measured and recorded. The rejects from the sample, weighing about eight pounds, were then placed in the box and thoroughly stirred with a spatula to work out all of the air. Then the box containing the water and ore was weighed, and the distance the water had risen in the box measured. The weight of a cubic foot of ore was then calculated by simple proportion. The weight per cubic foot of a number of samples containing different percentages of lead was obtained and a curve plotted showing the volume per ton corresponding to the various percentages of gangue-insoluble. The curve was so regular that the probable error in using it in obtaining the weight of any ore of a similar character was practically negligible.

Boise, Idaho, March 8.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cinnabar is known to occur at a number of places in Nevada, and some very rich quicksilver ore has recently been found there.

Potash is chiefly derived from the salt deposits at Stassfurt, Germany. The amount which can be produced and sold each year is regulated by the Government in order to maintain prices and prevent exhaustion of the supply.

The barrel-chlorination process was installed at the Mayflower mine in Amador county, California, in 1887, but was not a success, for the reason that the process at that time was not well understood. This process is now successfully employed at many places.

One of the foremost dredge miners of California has retired from the dredging industry and is engaged in planting fruit trees on the area of cobbles and sand created by his dredges in the pursuit of mining. The success of this undertaking should point the way to others.

The chloride and sulphide of gold are unknown in nature, though occasionally appearing in the reports of promoters on mines of which they have not the slightest knowledge. Any mine containing 'large veins rich in either the chloride or sulphide of gold' should be approached with suspicion.

Metals which do not readily oxidize on exposure to the air are gold and platinum, and to a less degree silver, aluminum, copper, lead, and zinc. Tin resists oxidation even better than the last three, though ordinary tin plate oxidizes rapidly, the central part being iron or steel with an outside coating of tin, in which it has been dipped.

Press dispatches announcing the discovery of rich ore in new districts are usually of greatest importance to those causing such news to be published. Once in a great while the facts are understated, through no fault on the part of the reporters, however. In most instances these reports are grossly exaggerated, no matter how rich the new discovery.

An original locator of a mining claim who loses it through failure to comply with the laws requiring annual labor or improvements, can recover nothing from one who re-locates the claim, either for work previously performed or improvements made. Even mining and milling machinery that may be on the property at the time of re-location can not be removed, as the former owner would be a trespasser and may not enter the property to remove the machinery placed there by him.

Guards for machinery that are well designed and neat are all too rare, and shafts and spindles, low pulleys and belts, intaking sides of gears, narrow clearances between fixed and moving parts, couplings, projecting screws, nuts and pins, and numerous similar risks on moving parts of machines as designed, are best handled for protection by the machine builder. In any case the safeguarding of these when within the reach of the operator is usually obligatory upon the employer and always desirable. If absent from machines when delivered the provision of such safegnards naturally falls within the field of the mechanical engineer of the plant.

Mining methods introduced in the mines of the Rand are interesting to mining engineers everywhere, but these methods in many cases are not generally applicable elsewhere. Rand methods, for instance, would in very few cases be available on the Mother Lode of California. On the other hand, Mother Lode methods are unnecessary on the Rand, owing to the wide difference in existing conditions. The conditions under which mining is carried on on the Rand may be said to be nearly ideal. The ground usually stands well, there is little water, and political conditions are such that the cheapest mine labor in the world is available. If conditions on the Rand were the same as in Colorado and California, the mines would mostly be idle.

Some mines are famous for the fine grade of the gold they produce, rather than for the amount. Some are famous for both. The Pike's Peak mine, in Cripple Creek district, is said to produce gold 999 fine. Mount Morgan, the famous mine of Queensland, Australia, turns out gold 997 fine, that is, from the upper portion of the orebody, the gold from the deeper part of the mine being lower in fineness. The placers of Juarez, Lower California, near San Diego, California, produce gold which sells for $20 per ounce, but unfortunately there is not much of it. The San Guiseppi mine near Sonora, California, produced nearly pure gold. Any light-colored gold is low grade, due to the presence of silver, and a reddish tinge indicates an alloy of the gold with copper.

Mining has not been generally recognized as a public utility, though there is one Utah decision that points in that direction. Mining enterprises can not exercise the right of eminent domain, and therefore mining adits can not be driven at will through the property of others for any purpose. The only way to overcome this is by organizing the company as a mining and transportation company, becoming a common carrier, and getting a charter which permits the company to engage in business of this sort. However, the company is then subject to the laws controlling railroads and other transportation companies, which may defeat the object in view. The Federal statutes governing the location of tunnel sites is plain. No tunnel claim may exceed 3000 ft. in length, and no vein location may be made on any vein discovered therein, not previously discovered on the surface, or elsewhere, that shall exceed 1500 ft. along the course of such vein.

Special Correspondence

LAKE SUPERIOR COPPER MINING

Experience in Re-Treatment of Copper Mill Tailing. — Michigan Copper, South Lake, Indiana, and Ojibway.

Probably $500,000 has been sunk in the Lake copper district during the past fifty years in unsuccessful attempts at re-treatment of tailing from the copper mills. In the early days only high-grade ore was milled, and the first operators depended mainly for their product upon mass and barrel-work, these being the heavy masses, often of many tons weight—masses of more than 500 tons having been yielded by the Minesota and Phoenix mines; while the barrel-work comprises chunks of native copper from a few pounds up to several hundred pounds in weight. The early mills were equipped with gravity stamps, and lost money on ore carrying 2%, or 40 lb. of copper per ton. Tailing losses necessarily were high in the early days, but have shown a gradual reduction. The old sands from the Osceola, Franklin, and Quincy mines are very extensive, while the Calumet & Hecla sand at the mills in Lake Linden, on Torch lake, amounts to more than 40,000 tons. The older sands are the richest. Extensive experiments at the Calumet & Hecla, conducted for nearly ten years past, have led to the building of a large re-grinding plant, and this is operating on a profitable basis, making a net recovery of about 5 lb. of copper per ton from tailing treated, at a cost of about 25c. per ton, giving copper in the form of unsmelted mineral at a cost of about 5c. per pound, allowing for smelting, freight, and incidental expenses. Copper from the re-grinding plant of the Calumet & Hecla is costing only about 6c. per pound, and the building of the Calumet & Hecla plant to treat its old tailing adds an asset worth millions of dollars to the company.

The Michigan Copper Mining Co. has ceased all exploratory work, owing to lack of funds. There remains a considerable tract of mineral land in the southern limits of the property unexplored and of unusual promise, lying as it does in the horizon of the several Adventure and Lake lodes. Tributers are at work in the Calico and Branch veins in the abandoned mine opened on these lodes, but are not taking out a great amount of copper. In the exploratory campaign just closed, 33 drill-holes were put down and the greater portion of the property was thoroughly drilled in an effort to find copper ground of commercial value. Several promising copper-bearing lodes were disclosed and these will be given proper attention when the funds necessary to carry on this work are forthcoming. The South Lake Mining Co. is doing work preliminary to drilling what will be designated as No. 12 drill-hole. This hole is expected to afford data regarding dip and strike of the several lodes disclosed in previous drilling, and will serve to determine the proper pitch and location of the inclined shaft which will be sunk to develop these deposits. The South Lake property apparently contains several lodes of great richness, but it is overlain by a heavy overburden of clay, sand, and gravel as thick as 260 ft. in places. The Indiana Mining Co. has temporarily ceased shaft-sinking until a head-frame can be erected over the shaft. The shaft has attained a depth of about 50 ft., and is therefore within 60 ft. of reaching the lode. The head-frame, which is in fact a part of the steel shaft-house that will eventually be erected at this point, will aid materially in sinking the concrete and steel drop-shaft, in that it will facilitate the handling of material in and out of the shaft. The Ojibway Mining Co., is developing copper ground of exceptional richness on the 1500-ft. level, tributary to No. 1 shaft. Driving in progress on the several levels above continues to disclose commercial ore at all points, and the showing in this shaft is highly encouraging. The shaft is sinking just below the fifteenth level. In the No. 2 shaft, sinking has been carried to below the seventeenth level. The drifts in ground tributary to this shaft do not reveal copper showings comparable with those in No. 1 shaft, and they leave much to be desired in this respect. The uppermost openings at this end disclose very lean ground, but this condition seemingly passes with depth, so that in the deeper laterals the showing is much improved. A material betterment is also evident as the No. 2 shaft drifts approach the No. 1 shaft. The general character of the ground in both shafts is better at depth than nearer the surface and the improvement apparently is widening as new depth is gained.

SOUTH AFRICA

Rand Geology.—Bore-Hole Prospecting.—New Rand, Limited.

Some very peculiar views regarding the geology of the Rand have been published lately. The local mining weekly surprises its readers by publishing such heterodox views as that the Rand banket reefs were of igneous origin. From the same quarter a peculiar geological map of a portion of the West Rand illustrated by even more peculiar cross-sections has made its appearance. The geology of this portion of the West Rand is certainly somewhat complicated, but the map and sections add to rather than diminish the confusion. It does not seem to be generally known that the area shown on the map as likely to constitute valuable mining ground has been repeatedly bored and proved useless, despite the promising aspect of certain surface indications; an occurrence which seems frequently to happen outside the charmed area of the Rand, extending, say, from Randfontein to Springs.

The search for a new Rand in the Orange Free State continues, but the Consolidated Gold Fields have become tired of spending money in this direction and have ceased prospecting operations for the present. Dr. Corstorphine, one of our leading geologists, will have learned by this how disappointing a task it is to look for the Main Reef series outside the Rand itself. His report to the Consolidated Gold Fields on the probability of finding the Main Reef series in the Orange Free State was very guarded in some of its terms, but on geological grounds was decidedly cheerful. Here again a little enquiry would have shown that this area has been well prospected in the past for the Main Reef series without success, although there were certain indications on geological grounds that lead one to believe that it ought to be there. It is dawning on some of our geologists that the Main Reef series is not such a constant series as might be supposed on geological grounds, for in new territory its place seems to have been taken by red shales, perhaps the Doornfontein red shales, but whatever they are they seem to occur very close to the Main Reef horizon. Several companies are interested in this Venterskroon, in addition to the Consolidated Gold Fields of South Africa, but none as yet has met with any striking success, a considerable area remaining totally unprospected. Some of the prospecting operations have been ill-advised, one firm even going so far as to put down a bore-hole in a practically vertical diabase deposit where the depth to the Witwatersrand beds must be enormous, and quite incapable of proving anything when reached.

Perhaps the most interesting task is that undertaken by the New Rand Limited, a company with £200,000 capital, under the guidance of A. R. Sawyer, which is also looking for the Main Reef series some forty miles farther to the east of Vereeniging. No less than thirteen bore-holes have been put down by this company, but always the same disappointing results follow—the ground is either faulted or unexpected intercalations of igneous rocks intervene, reducing the information obtained by every additional hole to much below that anticipated. As this kind of thing has happened to the last four bore-holes and every bore-hole penetrates seven hundred feet of useless coal strata, it is difficult to understand why the holes are not put much farther apart in order to gain additional information by proving the newer ground and avoiding useless boring. No. 13 bore-hole was equally disappointing, although in settled country, and there is every probability of No. 14 bore-hole doing the same, as where the formation is covered by coal measures it is difficult to select the best sites for these bore-holes.

BRAZIL

Diamond-Bearing Deposits.—Minas Geraes.—Bagagem.—Agua Suja.

The discovery of diamonds in Brazil dates back to the year 1729 when the first recorded diamond was found at Tejuco, now called Diamantina. For over 150 years Brazil held first rank as a diamond-producing country, but the opening up of the South African river-deposits and pipes ruined the Brazilian mines, and at the present time only a few mines are being worked where formerly there used to be a great number. Of the many States comprising the Republic of Brazil, Minas Geraes is the principal diamond producer, but it is from the State of Bahia that the carbonado or black diamonds for drilling are obtained. The western portion of Minas Geraes forms a triangle, and it is within this triangle that the Bagagem and Agua Suja diamond deposits now described are situated.

Bagagem, once the centre of an important diamond-mining industry, is situated on a river of the same name, and it was from the alluvial deposits of this river that large quantities of diamonds, including the well known 'Star of the South' and 'Dresden' diamonds, were obtained. Agua Suja is a village on a small tributary of the Bagagem, and its diamond-bearing beds differ considerably from the other sources of the diamond in Brazil, as they represent, with the exception of the Boa Vista mine, near Diamantina, the only spot in Brazil where diamonds have been found in what appears to be a locally formed deposit. The Bagagem alluvial deposits which contain the diamonds consist of recent gravels as well as ancient terraces, the former consisting of loose pebbles and large boulders of granite, gneiss, and schist. The river terraces are composed of the same rocks cemented together in a ferruginous matrix, and rise to an altitude of about 100 feet above the present stream. Both deposits have been worked, the recent gravel being the richer of the two. Along the valley, however, barren alluvial deposits occur, and this would seem to indicate that the patches of rich gravel in the Bagagem have not been derived from one general source, such as the deposition of a great bed extending over a vast area, but from isolated areas in which the diamonds occur in place. The non-occurrence of diamonds in the Rio Santo Fe and other river valleys must be accounted for by the rivers not having intersected diamond-bearing areas.

The following is the history and description of the Agua Suja diamond-bearing beds. In the year 1868 a miner named Sebastian discovered a diamond in the red earth near the banks of the Agua Suja. This led to a rush and in a short space of time, many hundreds of diggers were at work. Though the red earth yielded a fair amount of diamonds, the soft boulder bed upon which it rested was found to contain diamonds in greater number, and the number of diggers increased to several thousands, with the result that the workings were opened up for a distance of about a mile, where the beds were found to terminate at both ends against the schist formation. The African diamond discoveries then occurred, interfering with the output, and later on the deposit was taken in hand by a French company that is the present owner. It is clear, on close examination, that the soft conglomerate bed locally known as 'Taua' is the diamond bearer, and may be taken to represent the true home of the diamond in Brazil. Among the varieties of rock composing this soft conglomerate the following are the most numerous: pyroxenite or 'Pedra Verde', 80%; augite porphyrite, 5%; granites, schists, etc., 5%; sandstone, 5%, and other varieties of rock, 5%. The cementing matter consists chiefly of a soft red clay with numerous small, highly rounded pebbles of augite-porphyrite, probably constituting one-fourth of the entire bed, and it is in this cementing matter that the diamonds occur, together with the minerals associated with them, which are garnets similar in every way to those found at Kimberley, ilmenite, olivine, magnetite, yellow and red jasper, topaz, ruby, tourmaline, and rutile.

It would appear that all the rivers in Brazil in which diamonds are found in the alluvial grounds derive their precious content from similar conglomerates to those described. In fact, the Brazilian diamonds originate from beds of the Agua Suja type; and, in further corroboration of this view, there is the fact that the diamonds in Brazil vary in quality in the different workings just as much as they do in the different South African pipes. Buyers can distinguish the diamonds in Brazil and can tell the particular field from which they have been derived, while the boring carbons all come from one small and distinct area. In a contribution to the *American Journal of Science* on 'The Genesis of the Diamond', Orville A. Derby, director of the Geological Survey of Brazil, describes the Agua Suja deposits as follows: "In only one Brazilian mine, so far as known, are basic eruptions a characteristic feature, and in this the association seems to be accidental rather than genetic. This is the Agua Suja mine in the Brazilian district."

It must be noted that the diamond-bearing bed is a thoroughly decomposed breccia in which both matrix and included pebbles are transformed into clay. The origin of the boulders can, however, be recognized as well as the rock to which they originally belonged. The granite and schists upon which the diamond-bearing bed rests are also recognizable as well as the masses of the sedimentary and later eruptive series. Fragments of opal constitute a peculiar feature when this mine is compared with others in the same region or other diamond mines of Brazil. Still more peculiar and characteristic is the great abundance of magnetite and magnetite rock which Mr. Hussack has succeeded in tracing to a special magnetite-perofskite type found near Catalas in the State of Goyaz. The elements pyroxene, perofskite, and magnetite suggest a type of basic eruptions such as has actually been met in the Jacupirangu district of the State of Sao Paula in genetic relations with various nepheline-bearing rocks, the whole constituting a typical volcanic series. The Agua Suja occurrence thus offers a certain number of analogies to those of the Kimberley district of South Africa which are entirely lacking in other Brazilian localities as far as they are known, even at Bagagem, which is the same river basin. Baur says: "A new diamantiferous deposit has been discovered at Agua Suja, about 12 miles south of Bagagem. The diamonds are here associated with blocks of rock identical with that which occurs *in situ* not far away, together with much magnetite, and also ilmenite, decomposed perofskite, pyrope, and rutile. Some of the minerals, more especially the perofskite and pyrope, have not hitherto been found associated with the diamond in any other Brazilian locality. This association of minerals recalls the mineral constituents of the 'blue ground' of Kimberley in South Africa."

It will therefore be seen that there are in Brazil diamond-bearing deposits similar to those so extensively worked in South Africa, but so far as proved it is similarity in content rather than in mode of occurrence, because nowhere, so far as we are aware, have any true diamond pipes been discovered. It is therefore probable that instead of being obtained from pipes, the diamonds found in these alluvial deposits in the river basin may have been obtained from diamond-producing vein-deposits or dikes in the immediate neighborhood. The pebbles of which these alluvial deposits are composed are not only semi-angular, but can be distinctly traced to their source in local rocks, and have not been transported from any considerable distance. If the diamonds had been derived from a great alluvial conglomerate, as some authorities believe, they would not vary in character; but it has been already shown that the diamonds vary in appearance so much that buyers can distinguish the stones produced from the different fields. This fact would seem to indicate that the stones came from local deposits similar to the Agua Suja, and not from any great alluvial conglomerate deposits; while the fact that some portions of the same river valleys are quite destitute of diamonds also goes a long way to establish the view that their source of origin is local and not general.

BUTTE, MONTANA

East Butte Copper Co. Makes Improvements. — Interest in Radersburg.—The Raven M. Co. — International in Competition With A. S. & R. Company.

The East Butte Copper Mining Co. has commenced a number of improvements. A number of dams will be constructed to hold the tailing which will be re-worked. A new dust-chamber is in course of erection, and a new smokestack 15 ft. in diameter on the inside and 150 ft. in height will be built. This work will be completed in about three months. The company is operating two furnaces, and plans are being prepared for the erection of a third, while a mechanical ore-feeding device is also to be introduced. When the improvements outlined are completed the company will increase its output, and can place copper on the market at as low cost as any, according to R. H. Goss, the president, who also says that the grade of ore being hoisted averages 7% copper.

Reports of the finding of rich gold ore at Radersburg have brought a number of Eastern capitalists into the district. Within the past two weeks a number of claims have changed hands at a considerable advance on old prices. The Keating Gold Mining Co. has one of the best properties. The value of ore shipped from the Keating to the East Butte smelter is $35 to $40 per ton, while some returns have run up to $75 and $96 per ton. The property is now being opened on the 600-ft. level. The Black Friday, owned principally by Cincinnati, Duluth, and Boston people, will soon reach a depth of 700 ft. Some excellent ore is being found. The Butte & Radersburg, situated about one mile south of the Black Friday, is on the same lode. Sinking there has reached a depth of 160 ft., from which level a drift will be run 100 ft. north and south on the lode. About two feet of good ore has been opened at the bottom of the shaft. If reports are to be believed, the treasury of the Raven Copper Mining Co. is about depleted, and, so far as known, there is not enough in sight to warrant the stockholders in paying another assessment, which the directors are said to have ordered. Counting an exchange of the old stock at 25c. per share, an assessment of 25c. and another of 10c., 60c. per share has already been contributed by the stockholders, which leaves 40c. still due to bring the cost up to $1, which is the par value. Those in authority ought to furnish some information to the stockholders as to the condition of affairs. The Anaconda Copper Mining Co. has purchased from the North Butte company the Emily and Millview claims, which are the western extension of the Berlin claim, and which run along the north boundaries of the Elm Orlu and Poser, of the W. A. Clark holdings, and the Butte & Superior claims, while to the south of them is the Badger State. This purchase is in line with the policy of the Anaconda company announced some time ago, to secure all valuable properties offered at a reasonable price. The price paid for this property has not been announced. The Butte-Alex Scott is shipping an average of two cars of ore per day to the smelter, and good returns are received. Extensive development is being done on the 1400, 1500, and 1600-ft. levels, and a large tonnage of ore is being blocked out. The Little Annie, a property situated in the Walkerville district, and owned by the Alex Scott company, is again to be operated after having been idle three years. Men have been put to work erecting a new head-frame, putting a hoist in position, and preparing for electrical equipment. The old inclined shaft is to be abandoned and a new one sunk; this work will be commenced at once. During the time the mine was operated a few years ago the ore taken out averaged from 7 to 9% copper.

The new Washoe Sampling Works, being erected by the Anaconda company to take the place of the building destroyed by fire several months ago, are nearing completion, and according to present calculations will be ready to receive ore in about two months. People who had thought a treaty of peace had been signed between the Guggenheims and the Amalgamated Copper Co., have changed their opinions, owing to the announcement that an extension is to be constructed at the plant of the International S. & R. Co., at Tooele, Utah, for the purpose of treating lead ores. The Guggenheims have had a practical monopoly of the lead industry. The International company's plant at Tooele is understood to be controlled by the Amalgamated interests, and this latest move is believed to be an intimation to the Guggenheim people that they have had a monopoly long enough. The fact that the International has secured enough ore to justify the erection of the addition is taken to indicate that the Guggenheims have lost or will lose a considerable amount of the lead ore they have been treating.

ST. PETERSBURG, RUSSIA

Iridosmium.—Increased Silver Production. — High Price of Platinum. —Precious Stones.

Pending final returns of the year's mining in Russia, a few statements are available respecting one or two very interesting departments of the industry. It is known that iridosmium is associated with platinum. One feature of the sale of crude platinum to the foreign syndicate has always been that although the ore was sold on the merits of its platinum content—usually 83 per cent metal—the more valuable although, of course, less abundant associated metals, osmium and iridium, were entirely lost to the vendors. The refiners, in the process of refining the ore, obtained these very valuable metals, say from two to three per cent of the weight, for nothing. Iridosmium is produced in the Urals on the Miassk Mining Estate, in Western Ekaterinburg Mining Circuit, in the Kyshtim Mining Works Estate, and in the Northern Ekaterinburg Circuit. Unfortunately, during the last few years, this metal has not been produced so freely as before. It is obtained from platinum ore or mixtures of osmium and platinum. According to statements just issued, 14.9 oz. of iridosmium were obtained from the Urals, Miassk circuit, 37.23 oz. from the Western Ekaterinburg district, making a total of 52.13 oz., or 31 zolotniks less than in 1909.* To show the falling off, it will be interesting to read the returns for the last ten years, as follows: 1901, 19 funts, 17 zolotniks; 1902, 11f.; 1903, 11f.; 1904, 11f., 86z.; 1905, 8f., 14z.; 1906, 3f., 39z.; 1907, 5f., 24z.; 1908, 4f., 13z.; 1909, 4f., 29z.; and 1910, 3f., 93z. This makes a grand total for the ten years of 1080 oz. So far as is known up to the present iridosmium is not found anywhere in Russia except in the Urals. For a long time it was considered unfit to be worked, as it required an exceedingly high temperature to melt it, nothing lower than 1600° C. Iridium sheets and wire are now made of it, as well as thermo-couples capable of measuring temperatures up to 1600° C.

It is somewhat different with silver, as instead of being a diminishing quantity, the returns show that its production is increasing with great rapidity. Particularly is this so in the Urals, where for a long time silver production had been practically negligible. Without going back to so early a period as when silver was first found in the country, we may say that its production had practically ceased by the year 1894. Subsequently the metallurgists began to recover silver from the gold ore at the Kyshtim works and also at the Blagodat mines, and for the last ten years silver has been an item of growing importance in the country, as much as 452 poods being the result of the year's working in 1909, including the Blagodat mines' 367 poods and the Kyshtim works' 85 poods. In the year 1910, the quantity of silver recovered from Kyshtim was 66 poods and from Blagodat 350 poods. Besides the foregoing, other districts have contributed a share, but not such a striking one, to the total production, as follows: Altai (Tomsk), 66 poods; Nerchinsk (Transbaikal Province), 4 poods; Karalinsk (Semi-Palatinsk Province), 5 poods. Thus, as can be seen,

*1 pood = 526.65 Troy oz.
1 funt = 13⅔ Troy oz.
1 zolotnik = 0.137 Troy oz.

the Urals, according to information up to date, constitute the Russian natural silver ground.

The platinum production in 1910 was greatly stimulated by the abnormally high prices reached in the course of the year. The effect of these prices was to cause the miners to work at high pressure; although such did not occur all over the field, which is represented generally in the following districts: Cherdin, Perm, Southern Verchotur, Northern Verchotur, Southern Ekaterinburg, Northern Ekaterinburg. The leading district is Southern Verchotur, the production of which in platinum last year amounted to 210 poods, 26 funts, 24 zolotniks, 78 dolis. The next district in importance was Perm, the production of which was 87p., 19f., 2z., 78d.; the other producing districts being in the order of their importance, Southern Verchotur, Cherdin, and Southern and Northern Ekaterinburg. The total of the production was 334p., 23f., 41z., 41d., which compared with the total of the preceding year marks an increase of 22p.. 2f. Now this is not a correct statement. It is no doubt a correct statement of the platinum produced and duly reported to the Government, but this metal is so easy to smuggle that a very considerable percentage of the production is taken out of the country without being reported at all. How much this amounts to, it would be impossible to estimate. Figures of experts differ, but it would make an astonishing addition to the total reported above. 1910 was not a record year. It was beaten easily by 1901 with 388 poods; 1902 with 374 poods; 1903 with 366 poods; and 1906 with 352 poods. It seems that an exceptionally fine area, the Urals, is not producing platinum as it used to do. Only one conclusion can be read out of this, namely, that the sands are being washed out and new deposits are not being discovered equal to the old ones that have been exhausted; or there is the bare possibility, although it has not even been suggested by experts, that a larger proportion is being smuggled away. It is generally acknowledged that, failing some fresh discovery, it is going to be hard work to get back to the old level of production in the Urals as far as platinum is concerned.

One of the minor mineral industries of the Urals is very seldom mentioned, perhaps more seldom now than in preceding years because it does not appeal to the imagination like platinum and has passed almost entirely under the control of foreigners, namely, the searching for and polishing of precious stones. These may be said to consist principally of garnets and emeralds. For many years this furnished occupation for numerous peasant families in the Urals who had to struggle on in ignorance of the proper methods of dressing the stones for the market. It has long been known that these stones found their way mostly to Paris and London, where they were ground. But an English company has settled down on the ground, and, possessing as it does the most important mines of the field, is able to attract practically all of the precious-stone business of the Urals that is worth having. It is complained that this company simply collects the stones and exports them in their rough state to be polished in London, thereby depriving the natives of the occupation to which they had been accustomed for many years. An agitation is being raised similar to that which has brought to the front the now almost certain Government monopoly of the platinum industry. It is held by local industrialists that official steps must be taken to save what remains of the precious-stone industry from the absolute domination of the English (Isumrud-Emerald) company. Of course, garnets are very plentiful, and some other precious stones have been found in the Urals, notably diamonds, but these have only been found in limited quantities, and can not be said to have interested the outside world at all.

DEATH VALLEY REGION

Notes on the Formation and Mining Prospects of the Funeral Range.

That portion of the west slope of the Funeral range extending northwest from the Keane Wonder mine toward Boundary canyon, will soon come into the greater prominence it seems to deserve. It is a region of the ancient schists and limestones, capped in the higher parts of the range by quartzite. The schists and limestones, especially the former, are in the most contorted condition imaginable, the distortion being due to a series of intrusive dikes and sills of eruptive rock. The most prominent of this series is perhaps a grano-diorite. A true diorite of a darker color is less frequent. A typical granite can be seen, as well as an eruptive gneiss of a schistose character. A quartz-monzonite and a monzonite-porphyry occur. The two most promising localities, and where actual extraction of ore is in progress, are in and near Smith's canyon, and the Keane springs. The former is the first gulch northwest of that in which the Keane Wonder mine and mill are situated. The latter is three miles farther northwest. Both canyons practically head at the summit of the range. Keane springs are about three-fourths of a mile west of the crest. In the same gulch, about 1½ miles from its mouth, on the east edge of Death Valley, are a number of springs which supply water for the small Clapp mill. A short distance below the camp at these springs a small stream of water passes over falls about 100 ft. in height and sinks into the gravel. A wagon can be driven to the foot of the falls. Smith's canyon is where C. Kyle Smith was killed some two years ago, in dispute over a mining claim, by John Cyty, who was acquitted and has returned and is now working the disputed ground. He has just purchased the Harding mill of three Nissen stamps at Leland, California, and is transporting the equipment to his millsite at the mouth of the canyon. There is a spring of water there, and the mill is to be erected and put in operation soon. He claims to have two feet of good ore. North of Clapp canyon, in a most rugged section, is the Hartford-Montana property, where Arthur Burns is working under a lease, and is extracting good milling ore which he packs over a rough trail to the Clapp mill. On the south side of Clapp canyon, at the edge of the valley, where the vein can be easily reached by wagon, are the seven claims owned by Frank J. Grace and Frank O. Sharrock. They have a vein that follows closely the bedding between two varieties of schist, that on the foot-wall side being of a brighter and more greenish tint than on the other. At varying distances from the foot-wall, and never quite touch-

Upper End of Death Valley.

ing it, so far as noticed, may be seen small outcrops of a dark diorite of greenish tinge. The vein has been traced for the length of three claims. For a distance of some 450 ft. are several openings, all showing free-milling gold ore. This vein averages three feet in width, and contains heavily iron-stained quartz. At one opening is a small amount of copper carbonate and sulphide. It is a promising prospect, and is under option now at a price understood to be $50,000, the first payment being due May 1. Not far away are other prospects of considerable promise belonging to F. J. Grace, J. M. Callahan, W. W. Wilson, and others.

TORONTO, CANADA

Construction Work. — Shortage of Power. — King Edward Mine. — Diamonds in British Columbia.

The winter roads to Porcupine which were threatened with an early break-up owing to mild weather, have become firm again with the prevalent cold snap, and greater energy is being shown by the mining companies in forwarding freight. Great quantities of machinery are going in, and the leading mines will shortly be well equipped. A total of 73 stamps will be in operation during the coming season. The Hollinger will have 30 stamps, the Dome 40, the Vipond 1, and the Preston East Dome 2. All these are already on the ground or on the way. The Bewick-Moreing syndicate has been very active in erecting machinery at its two camps, one in North Tisdale and the other near Pearl Lake. It has put in five large boilers, with compressors and hoisting machinery. All this activity is reflected on the stock exchange. There have been numerous new flotations, some of which probably will never advance beyond the prospectus stage, but the latest count shows 10 listed companies, the shares of which are being freely dealt in, headed by the Hollinger, which bids fair to be the Nipissing of the Porcupine boom. While this stock has made considerable advances, the others are much less buoyant. Prominent among recent flotations is the West Dome Mines, Ltd., capitalized at $3,000,000, which has taken over the Foster property, adjoining the Dome, lately acquired by F. Augustus Heinze, who becomes president of the company. The shares are $5 each, and the underwriting of 100,000 at $2.50 gives the company $250,000 for development. A plant comprising a six-drill compressor, three large boilers, and hoist has been ordered for immediate delivery. The Vipond has taken over the Airth claim adjoining it on the east. At the Hollinger, 1370 ft. of driving has been done on the 100-ft. level, the vein for the entire distance running from 5 to 8 ft. in width. On the 200-ft. level the vein is exposed for a width of 10 ft. in a drift from a winze. The Tisdale has installed its compressor-plant, and the No. 2 shaft is down 85 ft. The Pearl Lake has let a contract to sink three 100-ft. shafts. A vein has been discovered on the 48-ft. level of the Crown Chartered which is believed to be the Vipond free-gold vein. A 30-hp. boiler and steam hoist have been ordered. At the North Thompson, adjoining the Hollinger, a vein has been stripped for over 200 ft., and shows visible gold. A shaft is down 42 ft. on the northeast corner, from which a cross-cut is being run in high-grade ore. Among recent prominent visitors to the camp were G. von Polenz of Berlin, representing German capitalists, and William B. Ridgely, former comptroller of the currency of the United States.

Cobalt is still handicapped by the shortage of power, but relief may shortly be afforded by the organization of a merger of the power companies of the district which are being taken over by the recently incorporated Northern Ontario Power & Light Co., capitalized at $7,500,000. It is understood that mining interests are well represented in the new organization. The Crown Reserve will build a 40-stamp mill in case the proposed concentrator for the Kerr Lake district is not built. There are 50,000 tons of low-grade ore on the dump and in the stopes ready for the mill, and this is accumulating at the rate of 60 tons per day. The Nipissing and La Rose have declared their regular dividends. The Treasurer's report of the latter company shows $1,079,000 on hand, but the directors adhere to the conservative policy of small dividends and large cash reserves. Milton T. Culbert, manager of the O'Brien mine, died on March 14 in the hospital at Toronto, where he had gone for treatment for appendicitis. He had been ailing for about three weeks and was only 30 years of age. Floyd Weed, formerly of Colorado, has been appointed manager of the Bailey. The annual statement of the Beaver showed earnings of $106,856, and ore at smelters, in transit, and on hand to the value of $143,403. The net income was $131,170. The King Edward property is to be abandoned, as all efforts to find silver ore at depth have proved fruitless. The Temiskaming is making arrangements to erect 10 additional stamps, increasing the capacity of its mill by one-third.

R. W. Brock, director of the Canadian Geological Survey, announces that diamonds have been discovered in British Columbia. They were found in peridotite on Olivine mountain near Tulameen river. They are quite small—none larger than a pinhead—but a series of tests showed that they were certainly diamonds of good quality. Owing to their small size and irregular distribution, the discovery is regarded as of scientific rather than commercial importance. The finding of diamonds in Canada has frequently been reported, but this is the first definite official announcement of such a discovery.

SEATTLE, WASHINGTON

Alaskan Oilfields.—Amalgamated Development Co.— Character of Oil.

The next important oil developments on the Pacific Coast promise to be in Alaska. Five or six years ago there was a good deal of excitement over the oilfields in the vicinity of Katalla, to the eastward of the mouth of the Copper river, but petroleum in commercial quantities was never found. The reason now assigned for the fact that shipments were never made is that the most promising wells were deliberately choked by contending interests that were each seeking to gain sole possession. During last year, new interests quietly bought what is known as the old English property, where most of the early wells were drilled, and these new owners plan to make the first shipment of Alaska oil about May 1, or soon after. Steel tankage to contain 37,000 barrels of oil is on its way from San Francisco to the North, and this is to be followed by nine miles of 4-in. steel pipe to convey the oil to the harbor at Controller bay. A line of 2-in. pipe is partly laid, but this was found to be inadequate to handle anything like the flow of the four wells on the property. A refinery of limited capacity is being constructed near Katalla to refine petroleum for the Alaska market. The new owners find a most satisfactory yield of oil. One well on a measured test yielded 720 barrels per day, while the other three brought the total up to 2100 barrels. This measurement of the wells was taken in December, in the presence of two officials of the Interior Department. The largest tank, of 30,000 barrels capacity, will be placed in position at the harbor. Its capacity will about fill an ordinary tank-steamer. A tank of 5000 barrels and one of 2000 barrels will be placed near the wells.

The Alaska oil locations were made before Mr. Roosevelt, as president, withdrew all the coal and oil lands of the district from entry. Titles have not been called into question by the Department. The oil territory is a belt about 25 miles long and 6 or 8 miles wide, along the coast to the north and west of Controller bay. Numerous seepages occur, some yielding two or three barrels per day. The Indians told the traders of the oil fifteen years ago, and in a year or so the best locations were made. A number of Americans formed the Alaska Development Co., which leased its holding to a Canadian concern, called the Pacific Oil & Coal Co., backed by McKenzie & Mann, now building the Canadian Northern railway across upper Canada. In turn this company leased to an operating concern known as the Pacific Mines Co., Ltd., which was to pay a big royalty as soon as oil was developed in "commercial

quantities." The three-cornered arrangement brought about the friction. The new owner is the Amalgamated Development Co. Dr. Burls, a London oil expert, in conjunction with his partner, Sir Boverton Redwood, made a report designating the spots at which oil was most likely to be found. Oil in varying quantities was found on each of the four locations that he first marked. Then the strife between the different interests began, and the wells were declared to be valueless for commercial purposes. The Alaska petroleum is not expected to compete with the California product, as the California oil has an asphaltum base and is chiefly valuable for crude fuel-oil, while the northern oil has a paraffin base, and should be refined. It is two-thirds benzine and kerosene products. The following analysis of the oil from a Katalla slough well is from the report of G. C. Martin, on the geological and mineral resources of the Controller Bay region, issued by the United States Geological Survey:

Katalla, Alaska.

Distillation.	Per cent.
Below 150° C., naphtha	38.5
150 to 285° C., illuminating petroleum	31.0
Above 285° C., lubricating petroleum	21.5
Residue, coke, and loss	9.0

Almost all the United States is supplied with gasoline from the Pennsylvania, Ohio, and other Eastern wells, although there is some of this more volatile product from wells in Colorado, and a little from California. Gasoline-producing petroleum is not too plentiful, and the market is ready to receive a supply from new territory.

NEW YORK

Interest and Activity in Porcupine Stocks. — The Hollinger. — The Dome and Other Mines. — Comment on Copper Mines. — The Amalgamated.—Alvarado M. & M. Company.

The one feature of overshadowing interest in New York mining circles this week was the sudden activity in Porcupine stocks and properties. There has been, during all of the winter, much desultory talk concerning Porcupine, but there has been no real sign of any widespread market activity. Now all this is changed, and without tangible reason for it. Inquiries about properties, orders for the purchase of stocks, subscriptions to syndicates are pouring in from all quarters. Printing-presses are suddenly busy turning out maps, prospectuses, and literature concerning Porcupine. Options are being bought and sold, and it has come almost overnight, so far as New York is concerned. A week since there was not a Porcupine issue quoted on the New York Curb; now there are a dozen, headed by the Hollinger, all actively traded in, and the list bids fair to have daily additions. The leader of the list of newcomers in the market is the Hollinger, which has shipped, so far, some $78,000 worth of ore, and will be in readiness to start regular production with a 30-ton mill by June 1. The company is capitalized at $3,000,000, in shares of $5 par value. These are selling at about $9, giving the property a valuation of $5,400,000. L. H. Timmins, one of the group that controls the company, said in a recent interview: "Porcupine, to my mind, will be a greater gold camp than was South Africa in the past. Porcupine ores are the easiest in the world to treat." The Hollinger will begin producing, handling about 150 tons of ore daily, which is expected to average about $50, and from which an 85% recovery is expected. The Dome property, controlled by the International Nickel interests, and by officials of the United States Steel Corporation, is to have a 40-stamp mill in operation in August, but this company has decided to treat the tailing, which will bring the average of its ores down to something like $10. One of the important deals of the week was the taking over of an option upon a 120-acre tract by interests connected with the Proprietary Mines Company of America. The ground is known as the North Dome and has an extraordinary surface showing. The deal was made by P. Kirkegaard, formerly general manager for the Deloro smelter at Deloro, Quebec, who bought the ground last fall. The price to be paid is said to be more than $100,000. Part of the Davison property is said to have been under option at $160,000, and to have been turned over during the past week at just twice this figure. Unquestionably, the figures given out will stand a heavy discount, but there is absolutely no question that the Eastern markets have suddenly awakened to the fact that a new gold camp is to be exploited, and that the public, which has been bored to extinction by all the devices put out to attract attention, is beginning to take an active interest.

The copper situation remains for the greater part unchanged. Copper-mining shares have lost place as market leaders. The starting of the mills at the Ray Consolidated and the Miami is looked upon apparently as a calamity rather than an achievement. The two companies are eventually to add 140,000,000 lb. of copper to the annual production of the country. Ray Consolidated is to turn out 100,000,000 lb. at an estimated cost of 8½ to 9c. per lb., while Miami is counting upon a production of 40,000,000 lb., to cost not more than 9c. Ray Consolidated belongs to the Guggenheim string of coppers, and will add its output to that handled by the Guggenheims as selling agents. Miami ore and concentrate will be sent to the Greene-Cananea smelter, and the product will be sold by the Amalgamated Copper Co. as successor to the United Metals Selling Co. The Amalgamated has sent out notices to the shareholders in the United Metals Selling Co. that it has purchased a controlling interest in the United Metals Selling Co. at $246 per share, and that it stands ready to purchase any and all other outstanding stock at the same price if offered any time before June 1 next. There has been some sharp criticism of the Amalgamated's action in issuing $12,500,000 of notes to take over the United Metals, suspicious noses having detected the odor of an 'inside' deal, whereby the Amalgamated company paid $12,500,000 for the privilege of handling its own copper. As a matter of fact, Amalgamated gets all of the long-time contracts which were held by the United, as well as $7,000,000 in cash and bills receivable, and 40,000 shares of International Smelting & Refining; these items alone make up enough in the way of book value to cover the price paid without leaving very much in the way of commissions to be taken down by any 'insiders.' There will be some important changes in the handling of copper metal, now that the United Metals is to be eliminated. When the late Henry H. Rogers became a factor in United Metals, he made his son-in-law, Urban H. Broughton, general manager, while Leonard Lewisohn secured the position of European sales agent for his son-in-law, Sir Charles S. Henry. It is more than likely that the foreign business will be placed in the hands of Henry R. Merton & Co., of London, who control the lead business abroad, and who are now very important factors in the European copper market. The present correspondent of the firm in this country is the American Metal Company.

The Alvarado Mining & Milling Co. is making a bond issue of $1,000,000. This company is in control of the Palmilla mine at Parral, Chihuahua, Mexico, originally operated by Pedro Alvarado.

General Mining News

ALASKA

COPPER RIVER

It is stated at Seattle that the Guggenheim-Morgan syndicate is to withdraw from all mining interests in Alaska, except as to the Bonanza copper mines at Kennicott. Its efforts, aside from the operation of this mine, will be directed to transportation, both steamship and railroad.

JUNEAU DISTRICT

The report of the Alaska United Gold M. Co. for the month ended February 15, 1911, is as follows: Ready Bullion 100-stamp mill operated 30 days, 13 hr., 38 min., having crushed 19,132 tons of ore, and saved 380 tons of concentrate. Estimated gross value of free gold recovered, $21,533; gross value of concentrate, $16,515; total, $38,048. Total realizable value of product, $35,553; operating expenses, $30,069, leaving a net profit of $5484. Construction expenses, $2007; yield per ton of ore milled, $1.99. The 700 Ft. Claim mill of 100 stamps operated 30 days, 17 hr., 4 min., having crushed 16,062 tons of ore and saved 280 tons of concentrate. Gross value of free gold, $21,540; concentrate, $16,172; total, $37,712. Total realizable value of product, $35,817; operating expenses, $24,702; net profit, $11,114. Construction expenses, $1590; yield per ton of ore milled, $2.34. Development work performed, 783 ft. on Ready Bullion, and 257 ft. on 700 Ft. Claim. Stock of ore broken, 2799 tons in Ready Bullion, and 10,876 tons in 700 Ft. Claim.

PRINCE WILLIAM SOUND

An area of about 7000 acres has been located on the Valdez flats as placer claims by those who believe this ground is sufficiently auriferous to make it profitable for dredging. It is stated that some of these claims are to be tested by a California dredging company. Much of the same area was staked ten years ago with the same object in view, but the field was not tested. The Amalgamated Development Co., according to statements accredited to Charles O'Connor, has a partly developed oilfield at Katalla, situated on Controller bay. It is claimed the company has put down six wells, three of which are yielding 1200 bbl. of petroleum per 24 hours. A dock is being built on Controller bay for the company's use, and a shipment of 20,000 bbl. of oil is to be made.

ARIZONA

COCHISE COUNTY

The Commonwealth M. Co., controlled by A. Y. Smith and associates, has built a cyanide plant for treating a tailing dump at the Commonwealth mine. The plant, which has the capacity of 100 tons per day, is equipped for the all-slime process of cyaniding, and is ready to be operated. The property is situated at Pearce.

GILA COUNTY

One 500-ton section of the concentrator of the Miami Copper Co. has been in operation since March 15, and the other three sections are expected to be operating some time this month. The design of the plant provides for two more sections, the foundations for which are built, but the equipment is not in position. The new mill was designed and constructed under the direct supervision of H. Kenyon Burch, the company's mechanical engineer, acting under the authority of B. Britton Gotzberger, general manager, and J. Parke Channing, consulting engineer. Concrete and steel were used to a great extent in building the plant. The foundation and floors are of concrete, containing about 15,000 cu. yd. of structure; and the mill building, sampling plant, and circular ore-bins are of steel. Practically the only way in which wood was used was in making the launders. The coarse-crushing plant consists of two No. 7½ gyratory crushers, and two sets of 54 by 24-in. rolls, the ore in passing from the crushers to the rolls being sized by four 10 by 4-ft. manganese-steel trommels. The ore, reduced to 2-in. size, is passed to the sampling plant by a 300-ft. belt conveyor, thence to four cylindrical steel bins, each 30 ft. diam. by 30 ft. high, set 24 ft. above the ground on concrete foundations. Equipment for automatic weighing is provided, the ore passing by gravity from each bin to the mill section opposite it. At the head of each section is a set of rolls by which the ore is ground to about ⅛-in. mesh. This is followed by classification over 22-mesh screens, the oversize being pulverized in Chilean mills having 30-mesh screens; the latter product unites with the screen undersize and this material is classified, the coarse passing to sand tables, and the fine to slime tables. The steam-electric power plant is housed in a steel building, 240 by 70 ft. in size, the steam being generated by four 600-hp. water-tube boilers, using oil as fuel. Included in this plant are three Nordberg engines, each direct-connected to a 1000-kw. electric generator; and two Nordberg air-compressors. The mill machinery is operated by electric motors distributed throughout the plant.

YAVAPAI COUNTY

Electric power has entirely supplanted steam power at the Humboldt smelter and at the Bluebell mine, both being operated by the Consolidated Arizona Smelting Co. The two properties use 1040 horse-power.

CALIFORNA

AMADOR COUNTY

The monthly dividend paid by the Bunker Hill Con. M. Co., on March 15, amounted to $10,000. The clean-ups at the mill during February were over $19,000. As the mill capacity has been increased, the output probably will be greater from now on. The property is in Amador. An electric hoist is being put in position at the Hardenburgh mine. The Amador Queen mine, which has been idle twenty years, is now an active property. It has a 1000-ft. shaft, but little lateral development. Its location is in Hunt's gulch. The Zeila mill of 40 stamps is not operating at quite full capacity. There seems an abundance of ore, but there are some obstacles in the way of getting it to the mill fast enough.

ELDORADO COUNTY

The Hope M. Co., operator of the Landecker gravel mine at Placerville, has 16 men at work in the mine and mill, and the force is to be increased. One air-drill is employed prospecting, and three drills are in use opening and blocking out the gravel in the channel. In this locality work is progressing at the Rising Hope, and Carpenter-Kumfa gravel mines; and the Bendfeldt, recently bonded to two Goldfield miners, is to be in operation by April 1.

INYO COUNTY

(Special Correspondence.)—J. E. Clark, a representative of the Bamberger and other interests of Utah, is opening a high-grade gypsum deposit near the old 'China ranch,' about four miles from Tecopa. He has brought in three carloads of machinery and lumber from Schurz and Rhyolite, Nevada, including hoists, crushers, gasoline engines, and other things necessary for operating. He has a contract with selling agents in Los Angeles for a daily extraction of 100 tons for use in plaster and cement. He is expecting to make other contracts for its sale as a fertilizer or neutralizer of alkaline salts in southern California soils. The T. & T. R. Co. will build a spur to the mine, and the product will be crushed on the ground, but shipped raw. A recent visit to the Skidoo mines, controlled by E. A. Montgomery, brings to mind again what mining men of nerve will do to win gold from mother earth. The claims embraced in the company's holdings are at a long distance from a railway. The ore could not be shipped, and water was not available near at hand for milling. After preliminary development, water was brought to mine and millsite through a pipe-line 24 miles in length, heading at large springs on the north slope of Telescope peak, at an elevation of between 8000 and 9000 ft. The elevation at the mill is between 5000 and 6000 ft. The 10-in. pipe is strong and expensive. The cost of getting some of it into position was enormous. The bill for wagon haulage

alone from the railway at Johannesburg to nearest road at the pipe-line was $75,000. The pipe-line cost nearly $300,000. Pressure is reduced at two or three points, so that when the water is delivered to the Pelton wheel at the mill its pressure is about 300 lb. per square inch. This water-wheel, with the assistance of one or two gasoline engines, runs the machinery at the mill and mine. The crushing machinery of the mill comprises two jaw-crushers of the Blake type, two 5-stamp batteries of 1050-lb. stamps, built by Hendy, and one 5-stamp battery of about 1300-lb. stamps, built by the Union Iron Works. The latter 5-stamp battery was bought and erected by lessees about a year later than the installation of the former two, and was afterward sold to the Skidoo Mines Co. The ore is mainly free milling, but in some places streaks of galena, copper, and iron pyrite occur. Below the apron-plates are three Deister tables. These collect during the month a limited tonnage of sulphide concentrate, worth about $450 per ton. Tailing goes direct to the dewatering and percolation tanks. The earlier tailing, in the tailing ponds, is from time to time elevated and run through the extra cyanide tanks. The ore is collected on the tunnel levels, and trammed in trains of mine cars by mule-power direct to ore-bins in the upper part of the mill. About $550,000 was expended on this property before any return was had. This amount came from the sale of 400,000 shares of treasury stock to Mr. Montgomery at $1 per share, and a further loan by him of $150,000. The first unit of the mill has been in operation about three years and the whole mill for nearly two years, though there have been many stoppages from breakage of pipe and other causes. There has been a total production to date of over $500,000. The loan of $150,000 has been repaid, and there have been two dividends of $50,000 each in addition, with probably over $100,000 now in the treasury. The ore mills from $11 to $16 per ton, with higher-grade streaks. The veins are strong and persistent on both strike and dip, with grade of ore holding up well on the lower levels. A large amount of ore is partly exposed, and the mine has undoubtedly a long life.

Skidoo, March 25.

NEVADA COUNTY

The Kate Hardy mine has passed to J. W. Morrell of San Francisco, and W. M. Beggs of San Jose, at a price said to be $80,000, in accordance with the terms of a bond given two years ago by Tyler Dudley. If the mine is not sold again within the next few weeks it is probable that Morrell and Beggs will operate it, and put in a number of improvements, including a 10-stamp mill. Ore of the value of $20,000 was mined during two months last year, but the mine has not been operated steadily. The Red Lodge mine, now in possession of an Idaho company, and situated near Washington, is being developed by two adits, by one of which great depth will be attained. The lower adit was started close to the South Yuba river, and was only recently commenced. It is reported that the Ironclad Gold M. & M. Co., having the Ironclad mine at Rough and Ready, is to re-open the property within the next two or three months. The holdings comprise 70 acres, situated close to Grass Valley; the equipment consists of a mill, power-plant, hoisting engine, and pumps.

SIERRA COUNTY

The Dragon Fly gravel mine is being operated by Squire & Simmons, who put in a power-plant whereby pumps are brought into use to keep the workings free of water, thus enabling them to take out the gravel to bedrock. The property is situated on the middle fork, near Engle ranch.

TRINITY COUNTY

(Special Correspondence.)—A gold-bearing lode, ranging 3 to 4 ft. wide, has been cut at a depth of 60 ft. in the Venica mine, near Lewiston. The ore assays from $15 to $20 per ton, and is partly free milling. The property is under a long-term lease to Collins, Paulsen & Collins, of Lewiston, and they have decided to install a gasoline hoist. During February the Headlight mine produced bullion valued at $18,200. It is expected that the March yield will be considerably in excess of this. The Headlight is situated near Carrville, and is owned by the Trinity Gold M. & R. Co. The final payment of $45,000 on the property was made a few weeks ago. The property comprises a hill of ore, about 400 acres of the overburden having been stripped off by hydraulicking. The ore runs about $3 to $4.50 per ton. It is understood that mining costs in February averaged 60c. per ton, and milling costs $1.10. It is expected to materially lower mining expenses shortly, as the advent of warm weather will permit the mining of the great deposit by the glory-hole method. The company is composed largely of Los Angeles people. David Goodale is manager. Developments at the No. 4 adit of the Bonanza King mine, near Trinity Center, have been progressing during the winter. The power-plant has been rebuilt, and the mill placed in condition to operate. It is planned to commence production at an early date. The Bonanza King was formerly the greatest producer of high-grade ore in the county, and originally was the property of the Treadwell brothers of Alaska. It is understood that a fair reserve of medium-grade ore has been developed. Several properties in the Lewiston district are preparing for a busy season.

Weaverville, March 24.

TUOLUMNE COUNTY

(Special Correspondence.)—Within a few days the Pennsylvania shaft of the Carlotta mine will have been unwatered and sinking commenced. It will be sunk 200 ft. deeper, as will also be the Carlotta shaft, and both will be connected by a level. The property was lately bonded to John Oleson, of San Francisco. A. B. Dodd, of San Francisco, and S. J. Silva, of Oakland, have purchased the Contention mine, in the Knight's Creek district, the consideration being $40,000, one-fourth of which sum must be paid before the extraction of ore is begun. The property has been developed to a considerable extent, and the outlook is good. It is being equipped with a 10-stamp mill. Development is to be begun at the Fleming mine by Walter Smith and associates, who have purchased some machinery for the property. Rich ore has been uncovered at a depth of 80 ft. in the old Tarantula mine, near the Rawhide, which has been bonded to George Stayton. A deep shaft was sunk on the property by former operators, but it does not follow the vein, and no cross-cutting was ever done. It is stated that the Jumper mine, at Stent, has been sold, and that R. S. Rainsford, for many years in charge of the Argonaut mine, in Amador county, has been made general manager, while Neil Cochrane has been retained as superintendent. The North Fork Mining Co. has sold a 2-stamp mill to the owners of the Gianelli mine, who will erect it on their property near Arastraville. It is reported that a London company will re-open and operate the Golden Gate mine, situated one mile southwest of Sonora, which has been idle for about fifteen years.

Tuolumne, March 20.

(Special Correspondence.)—The unwatering of the Spring Gulch mine is again in progress, after an interruption of several weeks caused by an accident, in which the skip was lost. At the Somerset, in close proximity to the Spring Gulch, rich ore is being taken out. Both properties are bonded to W. B. McCubbin and George Ash. The face of the adit, being driven at the Mt. Eden mine, south of Tuolumne, by W. D. Deming and George Wilds, shows 3 ft. of quartz that will give good returns in gold, and the owners are encouraged by the results of their work. A steam-hoist is being put in position at the property of the Springfield T. & D. Co., preparatory to sinking the incline shaft to the gold-bearing deposits, thus making possible the extraction of gravel at a cost much less than the present. The Jumper mine, near Stent, which was recently sold, was purchased by the Golden Rule Mines Co., of Maine. This company also bought the Golden mine, an adjoining property, from J. A. Smith. It is said to be the intention to sink the Jumper shaft several

hundred feet deeper. The Keltz mine is to be operated again by H. H. McIntyre and associates, of New York. The Kanaka mine, owned by Mrs. Agnes D. Parr, of London, is to be operated again. Some necessary repair work will be started at once. L. E. Parr, who will have charge of the mine, has arrived at the property. It is expected that operations will be resumed at the Rising Sun mine, at Arastraville, with J. E. Conde as superintendent. The property is owned by D. A. Porter and others, of San Jose, but is to be operated by Mr. Fancher and associates, of the same city, to whom it was bonded some time ago.

Tuolumne, March 26.

COLORADO

GILPIN COUNTY

The Gunnel mine, near Central City, is now thoroughly drained through a connection recently made with the Newhouse tunnel. A 200-ft. raise was driven from the tunnel to a blind level which had been driven from the base of a winze, the latter having started on the 1100-ft. level of the Gunnel. The drill-hole by which the connection was made let the water through with great force, and, while the miners were thoroughly wet, they escaped without injury. When the connection is enlarged to the size of the raise, the mine workings will be well ventilated. The distance from the portal of the tunnel at Idaho Springs to the Gunnel raise is 21,968 feet.

LAKE COUNTY (LEADVILLE)

The *Carbonate Chronicle*, Leadville, states that the Dinero and Sugar Loaf tunnels, which have been driven into Sugar Loaf mountain, have opened a fissure vein a mile in length, of an average width of 5 ft., the ore in which assays $50 per ton, and that these developments have proved the vein to a depth of 500 ft. The Siwatch cross-cut, now in 2700 ft., is soon expected to tap another great fissure of that part of the district. Thus it is seen that Sugar Loaf region is being developed by three important adits. The fissure veins of this mountain contain copper ore, and the making of great copper mines is anticipated.

The operators of the Wolftone and Castle View, on Carbonate hill, have connected the workings of the two properties to facilitate the extraction of zinc-carbonate ore from the latter. J. C. Hersey is shipping low-grade zinc ore from the dumps of the R. A. M. mine to the Western Chemical Works at Denver. An additional furnace has been brought into use at the Arkansas Valley plant of the A. S. & R. Co., making 5 of its 7 furnaces in operation. This is considered an indication of an increase of Leadville's production of silver-lead ores. Ores are also received at this plant from other counties, especially from Summit, Chaffee, and Pitkin.

PUEBLO COUNTY

The A. S. & R. Co. has all of its 7 furnaces in blast at its zinc-smelting plant, situated at Blende, near Pueblo. The zinciferous ores smelted are received mostly from Leadville, Silverton, Rico, Ouray, and from Chaffee and Clear Creek counties. A force of 400 men is employed at the plant.

TELLER COUNTY (CRIPPLE CREEK)

Lessees on the 400-ft. level of the Gold Dollar mine have opened a shoot of ore not previously known, and are breaking ore of a width of 10 ft. and which is said to assay 2 to 3 oz. gold per ton. The ore consists of calaverite in quartz. J. Carr has a lease on the Lonaconing mine of the El Paso Con., and expects to sink the 350-ft. shaft 200 ft. deeper. He is overhauling the hoisting and compressor plant. The Roosevelt drainage tunnel is discharging 10,000 gal. of water per minute. On this enterprise $550,000 was spent, but it is expected to result in lowering the former water-level to a depth of 400 ft., and render accessible a vast area of mineralized country, and relieve the operators of the expense of pumping. In anticipation of a much larger tonnage of mill ore being produced, several old plants are being overhauled to make them ready for the treatment of ore.

IDAHO

LEMHI COUNTY

The property of the Ima Con. M. Co., near Salmon, has passed under a 7-years lease to C. H. Huffy and J. Nolan. One condition of the lease is that the lessees are to build a 10-ton concentrating mill, and have it ready to operate by next September, and to increase its capacity annually thereafter. A. C. Fralik of Boise is at his mining property, near Shoup, which is to be further developed and equipped this season. Considerable tonnage of ore is blocked out, and it is probable that a mill will be erected next summer. The ore consists of gold quartz, which is suited to amalgamation and cyanidation.

OWYHEE COUNTY

The Banner M. Co., which has a group of mineral claims situated on Florida mountain, adjoining the Trade Dollar mines, at Silver City, has a large extent of developed workings, and a Nissen 4-stamp mill, having spent $160,000 on development and equipment, the latter including a transformer-house for electric power. It is reported that the ore blocked out is sufficient to keep the 30-ton mill operating a year. The ore is rich in gold, and is largely free milling. Peter Steele, one of the stockholders, and a practical mining man, has had charge of the property from the first.

SHOSHONE COUNTY

(Special Correspondence.)—B. M. Francis, in charge of the Rex mine, near Wallace, is shipping eight cars of ore per month, and expects to treble this output in a short time. Two more shifts of miners will be put on as soon as the mill is ready to run to its full capacity. It is now being used only to treat the ore taken out of the raise in the 500-ft. level. When completed the mill will have the capacity of 300 tons daily. The shaft is now down to a depth of 900 ft., and work is in progress on the east and west drifts of the 700-ft. level, and in the raise from the 500-ft. level. Sixty-five men are at work at the mine, and 22 in the mill.

Wallace, March 25.

NEVADA

EUREKA COUNTY

The Cortez district is close to the western border of this county, and Mt. Tenabo is a conspicuous landmark of that region. Its situation is about 35 miles south of Beowawe. Several mining properties in this district were highly productive in silver and lead from 1865 to 1890. One of these, the Garrison, is credited with having yielded an output worth $9,000,000. The group contains 33 patented claims, and there are 15 miles of workings. There are said to be good reserves of low-grade ore exposed in the mine at present. The Cortez Metal Recovery Co., which in 1908 erected a cyanide plant to treat certain oxidized silver-bearing tailing on the dumps of the Garrison, has operated with success. The Rossi mine, situated on the southwest slope of Mt. Tenabo, was likewise a big producer in early days, and has developed bodies of silver-lead ore in contact veins. It has been acquired by a company organized by T. C. Parker, of Battle Mountain, and financed at Des Moines, Iowa, and the mine is to be re-opened. A few miles away is the new property of the Tenabo M. & S. Co., controlled by Salt Lake people, who are preparing for further development. It is said there is now exposed about 8000 tons of ore that samples $13 per ton, and close to 17,000 tons assaying $3.50 to $4 per ton.

The Buckhorn mine, owned by George Wingfield, and being developed under direction of F. J. Siebert, is said to have a large tonnage of profitable ore blocked out between the 300-ft. level and the surface. It is stated that $350,000 has been spent in development and equipment. The property is not far from the Cortez district.

HUMBOLDT COUNTY

(Special Correspondence.)—The Edmonds-Schloss lessees on the Mayflower mine, at National, report some of the

richest ore ever found in the camp. The vein is 2 ft. wide, with 4 in. of talc and white quartz, the latter yielding ore of remarkable richness. The entire 2-ft. vein is said to carry milling ore of high grade. The find was made in a 105-ft. winze, 320 ft. from the portal of the adit. The approximate vertical depth at which the vein was opened is 335 ft. It is planned to sink the winze 20 ft. deeper and run drifts both ways on the lode. Joseph Schloss, one of the lessees, is from San Francisco. The National Mines Co. has declared its third dividend for the present year, making a total disbursement of profits of 35% on the capital stock for the first three months of 1911. The last dividend is at the rate of 10%, amounting to $80,000. This makes a total of $495,000 paid in dividends since last July. The production of the company and that of lessees on its estate for 1910 was approximately $1,750,000. The company is capitalized at 1,000,000 shares, but only 760,000 shares have been issued. The Cole-Bullis lease on Nineteen-Ten ground, now owned by the parent company, is proving one of the richest blocks of ground in the Barret Springs district. The vein is 3 ft. wide and most of the ore is of shipping grade. Some of it assays $200 per ton. At present seven tons is being extracted daily, most of this being incidental to development. Stoping will commence shortly. Shipments are being made to sampling works of the Western Ore Purchasing Co. at Hazen. J. M. Blood is superintendent. The Bi-Metallic reports the discovery of a new vein of rich ore. This property is about to make its first shipment to Hazen.

Winnemucca, March 23.

LYON COUNTY

The mines at Silver City are producing, many of them being worked by lessees. The McTigue mill has started up, and the three cyanide plants are being put in condition for the season's work. The Nevada Mining, Reduction & Power Co. has three shifts of miners at work on the Hayward mine, and is tramming the ore to its mill at Dayton.

The Mason Valley Mines Co., which is erecting a smelting plant at Wabuska, under direction of Jules Lebarthe, intends that its initial plant shall consist of two blast-furnaces for copper smelting, each 44 in. by 25 ft.; two stands of converters, a sampling mill having the capacity of 100 tons of ore per hour, and it is probable that one reverberatory-furnace will be built. Recently four electric locomotives were ordered for use in moving charge and slag cars. Transformers are being built, and the transmission line from the Truckee river to Wabuska is being established. This plant is to be operated partly on ore from the Mason Valley mine, and partly on ore from the mines of the Nevada-Douglas company. It is estimated that the former mine has exposed 1,074,635 tons of ore averaging 3.95%, 92,000 tons running 2.38%, and 100,000 tons assaying about 1.9% copper.

MINERAL COUNTY

The Rawhide Queen Mines Co., which has a 10-stamp mill, with concentrating-tables, at Rawhide, has purchased from the Pacific Tank & Pipe Co., San Francisco, complete equipment for a cyanide annex to the plant, consisting of two Trent agitating-tanks, two Dorr thickeners, an Aikens classifier, an Oliver continuous filter, tanks, zinc-boxes, and piping. It is learned that in the stamp-batteries cyanide solution will be used, that the sulphide will be recovered on the tables, and the tailing is to be cyanided. E. W. King is at the head of this company, as well as the Rawhide Coalition Co., the mill superintendent being H. S. Chapman. J. H. Barrett is one of the directors. The annex is to be ready June 1.

UTAH

BEAVER COUNTY

(Special Correspondence.)—During this month the Moscow has shipped three cars of ore, and two more are ready for shipment. February shipments amounted to two cars. These shipments netted about $1000 per car. Practically all of it was taken from a 150-ft. winze that was sunk below the 400-ft. level. The management is considering sinking a new shaft so as to catch the vein at a point about 1000 ft. on the dip, and much nearer the ore on the 550-ft. than the present shaft. On the Horseshoe Fraction a vein carrying 66% lead and 20 oz. silver per ton has been opened.

Milford, March 25.

JUAB COUNTY

(Special Correspondence.)—The item of interest in Tintic district has been the development on the Victoria. The orebody has been penetrated 40 ft. without reaching the opposite wall. The ore which is being sacked samples from $1200 to $1500 per ton. About 100 sacks have been filled, and it is hoped to make up one carload of ore of this grade. Directors of the Colorado have posted a dividend of 6c. per share, amounting to $60,000, making a total to date of $2,390,000. Grand Central is confining most of its work to developing, and a statement was recently made that 200 tons are being developed for every ton shipped. The cave recently opened in the Beck Tunnel is being explored, and it seems to be of greater extent than was first estimated. There is ore in a part of it. Shipments for the past two weeks have been slightly above the average, having been 175 and 170 cars, respectively. Iron Blossom and Centennial Eureka each shipped 46 cars last week, and the week before Iron Blossom shipped 46 and Centennial Eureka 42. Despite the increase in tonnage, Iron Blossom, much to the disappointment of the stockholders, passed the dividend that it was expected to declare this month.

Eureka, March 27.

SALT LAKE COUNTY

(Special Correspondence.)—John MacDonald, formerly of Utah Copper and later of Ray Con., is now in charge of mine operations at the Montana-Bingham. Mr. MacDonald developed the underground workings of the Utah Copper and, previous to that, of the Golden Gate. The Silver Shield has opened a 4-ft. vein of good ore in the winze on the main level. This makes two parts of the mine from which ore is being shipped, 150 tons having gone out within a week.

The Majestic Copper Mining & Smelting Co. has brought suit against the Miners' Smelting Co. and F. Augustus Heinze, to recover $20,000 alleged to be due as rental on the Majestic smelter at Milford since January 1, and interest from that date. The case brings to light an interesting deal. Mr. Heinze organized the latter smelting company and then obtained control of practically all of the stock. He also bought 150,000 shares in the Silver King Coalition and with the influence thus secured obtained a contract from the latter company for the smelting of its ores. The contract specified that Mr. Heinze must own or control a smelter in Utah, so the Majestic was leased for that purpose. The Silver King contract was sublet to the A. S. & R. Co. at a good profit, and the Majestic smelter was never started up. The owners now claim that the Miners' Smelting Co. has defaulted in its payment due in accordance with the terms of the lease.

Salt Lake, March 27.

SUMMIT COUNTY

(Special Correspondence.)—The extent of the recent discovery in the Silver King Con. has not yet been proved. The ore has been penetrated toward the walls in several different places, but each time it spreads into the bedding planes, so that there seems to be justification for the report when the find was made that it is one of the greatest in the history of Park City. Shipments for the past week were 1850 tons, with Silver King Coalition leading.

Park City, March 27.

TOOELE COUNTY

(Special Correspondence.)—The West Dip company, at Mercur, has shut down for an indefinite period. This company has been operating the Daisy Combination and has been treating about 65 tons daily in the mill, using the cyanide process.

Mercur, March 25.

(Special Correspondence.)—The Dry Canon district, north

of Ophir, is waiting for good weather which will put the roads in condition so that shipping may be resumed. Shipping was suspended the last of December, since which time the ore has been accumulating awaiting the time when the roads should become passable.

Ophir, March 24.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—J. W. Lloyd, manager of the Knob Hill, has also taken charge of the Trade Dollar, San Poil, and North San Poil, for the San Poil Consolidated Co., which has a bond and lease on each of those mines. The San Poil and the North San Poil are both producing a good grade of ore. On the 200-ft. level of the Trade Dollar a raise is being carried up from a point northeast of the shaft, and the ore being stoped samples about $20 per ton. About 150 tons has been broken and is ready to ship. The machinery on the mine is inadequate for hoisting the ore and waste required of it. The company intends increasing the force, and contemplates installing an air-compressor and an electric hoist. The compressor is to be at the San Poil mine, and air will be piped to the Trade Dollar for power-drills. Electric power will be drawn from the auxiliary plant of the North Washington Power & Reduction Co. The ore now broken will be shipped to the smelter before the new machinery is installed, and, for that purpose, a trestle will be built from the Trade Dollar dump, 100 ft. across the gulch, to a spur of the railroad.

The ore-shipments from the Surprise mine during February aggregated 36 carloads, averaging a net value of about $2000 per car. It is expected that the March output will be considerably larger. The third section of the North Washington Power & Reduction Co.'s mill is under roof, and the framework of the sampler will soon be under cover. A tramway will connect the sampling works with the main sections of the mill. It will be sustained by heavy pedestals, sites for which have been blasted out of solid rock. The first carload of machinery for the mill has been delivered, and the balance has been shipped.

Republic, March 24.

MEXICO

CHIHUAHUA

(Special Correspondence.)—The Veta Colorado Mining & Smelting Co., operating near Parral, is about to commence operations, and, to meet the demands of the new mill, has installed a number of electric generators and motors. The electrical equipment for the mines was first provided and comprised a 200-kw. generator with exciter, switchboard, and transformers; also two 75 and one 50-hp. motors for hoisting, as well as six pump motors, including two of 150 hp. each for operating station pumps, and one of 40 hp. This first generator is operated by a Hamilton-Corliss tandem compound engine. Subsequently, three additional 380-kw. generators were installed, with a corresponding number of exciters, switchboard, and lightning-protection apparatus. This additional generator capacity was necessary to supply power for the 40 or more motors distributed throughout the new mill and cyanide plant. This, in connection with the former electric equipment purchased for the mine, makes in all over 50 motors, having a combined capacity of between 1500 and 2000 hp. All of the electric apparatus was supplied by the Westinghouse Electric & Manufacturing Co. of Pittsburg, represented in Mexico by the Cia. Ingeniera, Importadora y Contratista S. A. With all of the machinery installed and in operation, this plant will be one of the largest and most modern among electrically operated mines and mills generating their own electrical power. A complete lighting system has also been installed. The Compania Industrial Mexicana of Chihuahua contracted with the Veta Colorado people for much of its mill machinery and construction work. Bernard MacDonald is general manager for the Veta Colorado M. & S. Company.

Parral, March 20.

GOLDFIELD CONSOLIDATED

In his report for February, J. F. Thorn, general superintendent, gives the following figures.

During the month of February, 1911, the total production was 23,675 tons, containing $973,730.78, or an average of $41.13 per ton, of which the whole was milled, with an average extraction of $38.59 per ton, or 93.84%. The total net profit was $719,325.04, or $30.38 per ton.

Development Work: 4220 feet of development work was performed during the month of February.

Operating Costs: The total cost of mining, development, transportation, milling, office, and general expense was $8.31 per ton, distributed as follows:

Mining:		
Development	$1.34	
Stoping	2.20	
		$3.54
Transportation		0.08
Milling		2.47
Marketing		0.48
General expense		0.42
Bullion tax		0.53
Construction		0.79
Total cost of operation		$8.31

Some work is being done on the old Reilly shoot, near the south end of the Combination No. 1 claim, which promises to open quite a tonnage of $15 to $20 ore. No new discoveries of any importance have been made in the Mohawk mine, but quite an area has been added to the new orebodies mentioned in last month's report. In the Red Top, Clermont, and Grizzly Bear mines there have been no new discoveries. In the Laguna some very good ore has been found on the No. 2 south level, and the indications are that this portion of the mine will produce quite a large tonnage of $15 to $20 ore. While no new orebodies of any great importance have been discovered during the past month, the known orebodies have been extended to a considerable extent, and the mines as a whole are looking exceptionally well. The production for the month of March will be approximately $900,000, or a net profit of about $700,000. During the month practically three days were lost on account of a break in the power-line somewhere in the White mountains.

AMERICAN MINING CONGRESS

The directors of the American Mining Congress, the permanent headquarters of which are in Denver, have selected Chicago as the meeting place for the 1911 session, which will be the fourteenth annual meeting of this body. The exact date has not yet been selected, but it will probably be some time in October. The official call for the convention will be issued shortly, authorizing the appointment of delegates to the meeting. It is probable that this will be the last session to which outside delegates will be appointed, as the directors have for some time been working out plans for the abolition of the delegate system, and permitting only members of the American Mining Congress to participate in the proceedings. The Mining Congress is agitating the adoption of workmen's compensation laws by the various coal-mining States with the object of providing a fund, by a small tax on coal production, to furnish indemnity for the victims of mine disasters and a pension for aged mine-workers. Recently a committee of the Mining Congress drafted a bill for a law of this character which is now being submitted to the legislatures of many mining States for their consideration. The Mining Congress is also working for more efficient inspection and regulation of coal and metal mines with a view to decreasing the loss of life in mine disasters; the standardization of electric practice in mines, the general revision of the mineral-land laws, and other matters. These and other problems will be discussed at the Chicago meeting.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

GELASIO CAETANI is at Rome.

ALBERT BURCH is at Goldfield.

MARK B. KERR was in San Francisco.

H. S. CHAPMAN was in San Francisco recently.

P. L. EBERHARDT, of Wallace, Idaho, is in San Francisco.

EDGAR A. COLLINS will leave in April for London and South Africa.

JOHN B. FARISH, of Denver, was at the St. Francis hotel, San Francisco.

P. A. WICKHAM was in San Francisco, and has gone to Alamos, Mexico.

A. J. MCCONE, of Reno, was at the St. Francis, San Francisco, last week.

CARL O. LINDBERG, of Spurr & Cox, Inc., visited San Francisco this week.

L. J. MAYREIS has returned to Collahuasi, Chile, from a visit to the United States.

FRANK KLEPETKO has been examining the Ferrobamba copper property in Peru.

DOUGLAS WATERMAN, manager for the Gigantic M. Co., in Salvador, is in San Francisco.

H. F. REID is lecturing at the University of California on 'The Mechanics of Earthquakes.'

JAMES E. CHAPMAN is engineer for the Guanajuato Con. M. & M. Co., Guanajuato, Mexico.

CHAS. E. BASCOM, of the Broderick & Bascom Rope Co., St. Louis, Mo., was in San Francisco.

C. M. FASSETT, of Spokane, who has returned from the Orient, was in San Francisco last week.

VICTOR G. HILLS is consulting engineer and manager for the Scheelite Mines, Ltd., in Halifax county, Nova Scotia.

C. B. NAREMORE has resigned from the U. S. Geological Survey to accept a position with the Associated Oil Company.

W. H. WEED is at Arispe, Sonora, but will go shortly to Cumpas to examine the properties of the Transvaal Copper Company.

ROBERT GORDON, mine superintendent and engineer for the Montezuma Mines of Costa Rica, Central America, has returned to the mines.

F. H. HILLMAN, who made an enviable record as manager for the Standard Oil Co. in Illinois, has been transferred to California, and has established headquarters at Bakersfield.

W. C. MADGE, formerly metallurgical engineer for the Yampa Smelting Co., sailed March 22 on the *Lusitania* for London, where he will design a smelter for an English company operating in Russia.

S. E. BRETHERTON has returned to San Francisco from Shasta county, where he was looking after the development work for the Bully Cave company, near Winthrop, and the Afterthought company, at Ingot.

T. E. DICKEL, recently foreman of the cyanide plant at Minas del Tajo, Rosario, Sinaloa, Mexico, is to take a similar position with the North Washington Power & Reduction Co., at Republic, Washington.

C. W. PURINGTON was at Chita, Siberia, lately for the Russo-Asiatic Bank. Mr. Purington has resigned as manager for the Orsk Goldfields Ltd., though he remains connected with that company in a consulting capacity.

C. H. MUNRO will sail from San Francisco on the *Korea*, April 18, to spend the summer at the Koichan Mines, of which he is now general manager for the Orsk Goldfields Ltd. Mr. Munro will be accompanied by W. H. LANAGAN, who will be assistant manager, vice D'ARCY WEATHERBE, resigned.

Obituary

THOMAS RICKARD, who died at his home at Berkeley, California, March 25, following heart failure and a fall from his bedroom window, was a mining engineer well known and well liked throughout the West. He was a son of Reuben Rickard, one of the pioneer mining engineers of California and Nevada, and a nephew of Thomas Rickard of London. Edgar Rickard was his brother and T. A. Rickard his cousin. Thomas Rickard was born in France in 1869 and graduated from the University of California in 1887. He lived in Nevada, practising his profession for a year after leaving college, and then returned to San Francisco, where he took an interest in the firm of Parke, Lacey & Company, sellers of mining machinery. In 1901 he joined J. O. Harron and Alex McCone in buying out the older firm, the name being changed to Harron, Rickard & McCone. He was vice-president of this concern at the time of his death. Mr. Rickard was a man of wide interests, but found time to be active in public affairs, having served as mayor of Berkeley, as member of the Chamber of Commerce, and as trustee of the California Institute for the Deaf and Blind. He was prominent in lodge and club circles. He was a man everybody liked, and in a quiet, unobtrusive way he did his part in helping the many with whom he came in contact.

Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

JOPLIN LEAD AND ZINC PRICES

The highest price paid for zinc sulphide ore in Joplin district during the week ended March 18 was $45 per ton, the base price ranging from $37 to $42 per ton of 60% zinc. Zinc silicate ore sold on a base of $20 to $24 per ton for that running 40% zinc. The average price of sulphide ore was $39.60; zinc silicate, $22.30, and all grades, $38.36. The highest price for lead ore was $56 per ton; the average of all grades, $54.38. Most of the ore shipped for the week was from the stock purchased the week before. The metal shipments for the week ended March 18 were 11,914,740 lb. zinc, 2,119,370 lb. lead; for the 11 weeks ended that date, 109,768,040 lb. zinc, 19,179,290 lb. lead.

THE NOVA SCOTIA STEEL & COAL CO. has increased its dividend from 5 to 6%. Its profits for 1910 were $1,140,504, as against 907,949 for 1909, the increase being partly due to the re-financing of the company, whereby the interest on its bonds was reduced from 8 to 5½%. The company has $493,787 cash in hand. The value of current assets is $2,351,326, an increase of about $348,000, while current liabilities have decreased from $999,109 to $555,039. The position of the company in regard to current assets is therefore nearly $800,000 better than last year.

TABLE OF CONTENTS

EDITORIAL

CONTRADICTING rumors occasionally industriously circulated, we announce that the *Mining and Scientific Press* is not for sale; neither is there any intention of removing its headquarters. Over a half century ago, with the whole field free from competition, the founders of this paper chose San Francisco as the place of publication, and they chose wisely. The city is now, as always, a great mining centre with close ties to the whole Western mining region and with a growing influence in the countries that border the Pacific, the greatest field remaining to be developed. We give the mining news of this territory, and serve the mining men of the world. Having survived earthquake and fire, good times and bad, for fifty-one years, we feel that we have a right to this as our home.

THE AMERICAN-JAPANESE commercial treaty has been formally ratified and most cordial relations between the two governments prevail.

ANOTHER notable Swiss tunnel was completed on the last day of March when, after five and one-half years work and the expenditure of twenty million dollars, the Loetschberg tunnel on the route from Milan to Berne was completed for the nine miles of its length. For speed of tunnel-driving the palm goes easily to American engineers, but for ingenious methods of coping with unusual difficulties the Swiss tunnels will long remain famous.

MRS. ELLEN H. RICHARDS, who died at Boston last week, was a notable example of the eminence to which a woman may attain in scientific work. As a member of the teaching staff of the Massachusetts Institute of Technology for over thirty years, as a member and officer of various learned societies, and in varied public services, no less than in the gentler duties of the home, her achievement was great, and her passing leaves profound regret in many hearts.

APPROPRIATIONS by the State for experimental work in metallurgy are urged by the *Herald-Democrat* of Leadville, Colorado, which points to the immense quantities of low-grade ore that would be made available if processes could be improved. That smelting of precious metal-bearing ores has reached as high a state of perfection as can be expected has recently been stated by so good an authority as Mr. Franklin R. Guiterman, but it is doubtless true that in the broad field of research connected with ore-dressing and hydro-metallurgy, there is room for helpful work in the laboratories at the State Universities and the School of Mines.

CONCENTRATES, one of the long-established departments of this paper, is evidently widely read and appreciated. A number of the country newspapers publish a column each week taken from this department, carefully crediting it to the *Mining and Scientific Press*. Others are not so scrupulous. A contemporary technical publication that makes a great parade of virtue used nearly a dozen items from this department in one recent issue, without a line of credit.

THE MASSACHUSETTS INSTITUTE of Technology celebrates its fiftieth anniversary in Boston this week, and will mark the event by a 'Congress of Technology' at which the sober pursuit of science will be varied by lighter diversions. The list of speakers for the technical session is long and one that includes the names of men who have been significant factors in the progress of the last half-century. A year the senior of the Institute, we extend to her our congratulations upon her fiftieth year of successful work, our admiration for what she has accomplished, and our sympathy with the ideals she is striving to realize.

RAILWAYS in the United States have adopted a policy of frank publicity, and it will, we believe, be greatly to their advantage. The recently established 'Bureau of Railway Economics' publishes monthly bulletins showing revenues and expenses in different geographical regions. This bulletin is sent free to the press with the statement that "while of course you are at liberty to make use of the information, it should be understood that this offer is made entirely without request or suggestion that the bulletin be made the basis of published comment." That breathes the right spirit. With increasing control of railways through commissions, there is the greatest possible need that the public be given exact facts promptly. Complete understanding usually leads to complete agreement.

PROTEST has been made to us by a Slavonian miner against the phrasing of our correspondent's account of the labor troubles at the Homestake. He writes a manly and dignified letter protesting that the Slavic people in America are misjudged and indicating clearly that he, at least, has studied American history to advantage, and has acquired much of the American point of view. It is easy to overlook the good qualities of those whose language and customs differ from our own. A few decades ago the Irish immigrants suffered from the same prejudice that the Slavs have now to meet. Today the Irish are more vigorously American than many who come from earlier stock. When, following the troubles of 1848, many Germans came to the United States, even university graduates were judged uncouth, and set to digging ditches. We trust that the Slavs may prove their worth as successfully as the Irish and Germans have. In the meantime, it may comfort our friend to learn that we know at least one engineer who pays premium wages for Slavonian labor.

WHAT has become of the plans for a new building at Washington to house the United States Geological Survey and related Bureaus? The conditions under which the geologists write their reports may be illustrated by the fact that in one room, eight by fifteen feet in area, with two windows, five persons work. Under the circumstances, we are not particularly enthusiastic over the twenty-two pages of the Sundry Civil Bill on which are listed appropriations for post-offices from Aurora, Nebraska, to Ypsilanti, Michigan.

CONSERVATION in its legal aspects has given rise to much controversy. At the first White House conference Mr. William J. Bryan applied the phrase 'twilight zone' to that borderland between State and National authority within which land-grabbing corporations were assumed to find the greatest scope for future activity. There has been a general belief that the shadows lay deep over this territory and that it was big with strife and evil. We are glad to present a more cheerful picture in the admirable summary of the limits of State and National authority as regards conservation, in the form of an address delivered by Mr. Curtis H. Lindley at the dinner given by the Commonwealth Club of San Francisco to Mr. Theodore Roosevelt. To say that it is the best statement of the situation yet given the public is but to echo the opinion of the thoughtful students of conservation who heard or have read the address. Its brevity leaves no room for anything but the analysis itself; arguments for or against are not given. It is impartial and authoritative, and an excellent illustration of the public service that a great lawyer can render by making clear to laymen the fundamental legal principles applicable to a public question of wide moment.

Alaska and the Public Lands

Alaska and its problems have been much discussed in the last few years, though not all that has been said is either true or helpful. The discussion has, however, served to focus attention, and to that extent has prepared the way for better conditions. Alaska has suffered from having no authorized spokesmen, and multiplicity of counsel has confused the issues. We present elsewhere the report of the Alaska Committee of the American Mining Congress, prepared, after nearly two years work, by men familiar with the country and having an interest in its future. Amid all the confusing and frequently belligerent briefs that have been filed, this one impresses us as particularly sound and judicial. It will well repay careful study. We are in substantial agreement with the conclusions and recommendations of this committee. That Alaska needs better administration rather than more law, that the coal lands should be opened, that existing titles and claims should be promptly adjudicated, that a land court is desirable, that a leasing system is applicable, and that both laws and regulations should encourage rather than discourage the prospectors, we have repeatedly urged.

It is all too easy to ask and even to secure new laws; and it is much too difficult to secure effective administration of law anywhere in the United States. If that be so where population is dense and customs are established, it is but natural that in the Far North, a land of wide extent, of scant population, and of many transients, poor administration should be common. Added to the inherent difficulties of the situation, is the circumstance that Washington has kept tight hold of too many things. It has been too often true that a permit or paper had to go to Washington for approval before an improvement could be undertaken; which at times meant a season's delay. Local officers of all ranks should be given wide authority and then rewarded or punished as they used or abused it. In Government service, shirking responsibility and passing decisions up to a higher official is common. It makes life easy for the subordinate, but hard on the ranking officers and on the public. A few mistakes might well be borne in the interest of prompt transaction of business. Appeal on reasonable grounds or in matters of magnitude should, of course, always be open.

That the coal lands are the key to the future and that the solution of the problem of their disposition is Alaska's most pressing need, will be generally conceded. Fuel is at the basis of civilization, and Alaska undoubtedly contains a great reserve of high-grade coal available to dwellers on the Pacific Coast. At present the abundance of California oil relieves the situation, but in the end reliance must be placed upon Alaska's resources of coal, and perhaps petroleum. Even now there is a market for a certain amount of coal, estimated by Mr. A. H. Brooks at approximately a million tons per year. With great fields easily available, locomotives in Alaska burn imported coal. It is not so important to place the blame for this as to find the remedy, and for that the people look hopefully to Mr. Walter L. Fisher, the new Secretary of the Interior. He has the confidence of the public and will doubtless find a way to speedily adjudicate the numerous conflicting claims and allow the opening of such lands as are really subject to patent. Looking farther afield, we note with interest that the committee found but little objection to the application to coal lands of a leasing system, provided that it was made equally applicable to public coal lands in the Western States and Territories, and that the revenue be used locally. Both of these contentions we believe sound; at least to the degree that the bulk of the income, after paying expenses of administration, should be devoted to local needs. In some cases the amount available would be more than could be used to good advantage, as in certain parts of California where the portion of the tax on railroads collected by the State but returned to the counties, is enough not only to do away with any local taxation, but to support county governments of unusual extravagance. The plan adopted in connection with the Reclamation Service has merits. Under existing law every cent derived from the sale of public lands must be spent in the public-land States. A large part, fifty-one per cent, must be spent on reclamation projects within the State or Territory where it originates. The remaining part may be temporarily diverted to some other public-land State where the amount available is smaller or the need greater, though it remains as a credit subject to ultimate repayment for use where it originated. When the law passed, Oklahoma, for example, had small need for irrigation, but a large fund, since the public land there sold promptly. Wyoming had large needs and but small funds. Part of Oklahoma's surplus could therefore be diverted temporarily to Wyoming to advantage.

The most significant point, however, should not be overlooked, that money derived from sale of Western lands is spent in the West and not in the East. Those who have attempted to make capital out of a supposed desire of Eastern conservationists to profit from the West, have too frequently overlooked this point. The same principle has been applied by the Forest Service when a part of the income from sale of timber is directly paid to local governments; the remainder is used for building trails, fighting fire, and for other similar purposes to the benefit directly of the States and Territories in which the National Forests are situated. This same principle should be recognized in any leasing system applied to the coal lands of Alaska and the West, or indeed to any of the public lands. If this be done, and if the system be framed so as to give proper encouragement to the prospector, we see no reason why it may not be advantageously applied to both oil and coal lands. Local officials must have the authority necessary for prompt transaction of business, the bulk of the revenue must be available for local needs so long as they are acute, and the legitimate prospector must be recognized and rewarded, or any system of leasing will be unpopular in the West as well as in Alaska.

Since the foregoing was written, the United States Circuit Court at Seattle has handed down a decision in the Alaskan coal land cases now on trial, which appears to sanction some of the methods which have been employed in securing large areas of the coal-bearing lands belonging to the public domain. Until full details of the decision have been received generalization upon it is worse than useless, but it is to be hoped that further confusion and legal entanglement has not been added to the already too great mass of it. The execution of laws should be just, simple, and direct. An injury will be done to our commonwealth if the coal lands of Alaska are allowed to pass into the control of big corporations without some adequate return being made. But it must not be overlooked that if the methods employed in preventing their passage under such control are so involved and unwieldy that as a net result the development of the lands is unduly hampered and delayed, injury will also accrue. Recently there has been much talk of 'efficiency' in the administration of railroads. It ought not to be too much to hope that the infection will spread and that the execution of laws may be conducted more with regard to the attaining of substantial justice and less with regard to legal intricacies.

National and State Authority in Conservation

By Curtis H. Lindley

*Whether there is a doubtful zone between National and State authority in conservation may only be determined by considering the State's relationship to the National Government in regard to the public domain within its borders; the areas over which State laws are dominant; the powers of the Federal Government acting within these areas—first as a sovereignty exercising governmental functions, and second as a landed proprietor, owning and controlling the disposition of the land which constitutes the basis of its conservation policies. In submitting what follows, I may explain that the generalizations may in some minor phases be subject here and there to exceptions, owing to difference in environment. I am dealing with the situation as I understand it to exist in the State of California.

With reference to other States, while the differentiation may be slight, there is no time to explain, elaborate, or note exceptions. The heart of the subject may best be reached by a process of elimination. We may state the following as postulates—principles which, I understand, have been established by the highest judicial tribunals, both State and National.

1. In the beginning the Federal Government owned none of the Western lands; nor did it ever own nor has it since acquired any 'public land' in the larger sense within the present boundaries of the thirteen original States or those carved out of them. Tennessee and Texas also fall into this category.

2. The first cession of territory to the Government came from the original States, and vested in the United States, roughly speaking, the area extending westward to the Mississippi. The terms of cession created a public domain which was to be the theatre of future States, and was to be held by the National Government in trust for all the people. Each State carved out of this territory entered into a compact that it should never interfere with the primary right of disposal of the soil, or subject the land to taxation so long as the title remained in the Federal Government. The Constitution of the United States, as ratified by the States, contains the following brief clause with reference to the public lands: "The Congress shall have power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States, and nothing in this Constitution shall be so construed as to prejudice any claims of the United States or of any particular State." Subsequent additions to the public domain were acquired through treaties of cession and purchase, and States subsequently created out of the added areas were admitted into the Union under like compacts and under the aegis of the Constitution.

3. The States, as such, acquired no right of property in this domain by virtue of their sovereignty except lands underlying tidal waters and navigable streams, such rights being subordinated to the public right of navigation, which is under the control of the National Government. Whatever other property the States acquired on admission or subsequently, came through donations by the National Government for educational and other purposes, such as sixteenth and thirty-sixth sections in each township for schools and lands granted for agricultural colleges, universities, and like purposes. In the exercise of what may be termed its agrarian policies, the National Government has sold into private ownership lands to actual settlers and other purchasers, and has donated large areas to aid in the construction of railroads, wagon-roads, and other internal improvements. The residuum, until recently a rapidly disappearing quantity, is the 'Public Domain', subject to national conservation.

4. Within the States, the Federal Government is to be considered in a dual aspect. (1) Landed proprietor, holding the public domain in trust for all the people; and (2) a sovereign exercising such powers and governmental functions as were granted to it by the States upon subjects defined in the Constitution; such, for example, as the right to regulate commerce between the States, the control of navigation, and others not necessary to enumerate.

5. Under the Constitution and compacts between the States, the Congress of the United States has the absolute control over the public domain. It determines all questions of policy with regard to its disposition. It may reserve it from sale; donate it; lease it; and prescribe such terms as it may see fit for privileges granted on or over it, the same as any other land-owner. With this policy the State has no concern, and can not interfere.

6. With the exception of such small areas as are occupied by the National Government for purely governmental purposes, such as post-offices, customs offices, etc., as to which the State has in express terms surrendered its sovereignty and ceded it to the National Government, the State exercises what may be loosely called the 'police power' within its entire boundaries. All ordinary State laws passed in the exercise of its political jurisdiction are operative over the public domain, provided such laws do not contravene the compact between the State and the National Government—that is, do not interfere with the primary disposal of the soil, and do not impinge on the constitutional power of Congress to deal with the lands as it sees fit.

7. For purposes of this analysis, we must consider the State solely in its sovereign capacity and not as a land-owner. In California, at least, by a process of rapid elimination, the State has ceased to be a land-owner. Such landed property as it may still own, and which has escaped the pernicious activity and piratical vigilance of 'land sharks' and speculators, is purely negligible.

8. National conservation, as we understand it, is

*Address at dinner given to Mr. Theodore Roosevelt by the Commonwealth Club, San Francisco, March 27, 1911.

a policy of primarily placing the remnant of the public domain, other than that portion of it which is purely agricultural in character, in a state of reservation, and subsequently dealing with it or its natural resources in such a manner as will economically yield the best results to all the people. Its principal aim is to obtain a maximum economic production at a minimum of waste: to prevent individuals or aggregations of individuals from securing monopolies: and to exact some equivalent for the privileges granted. It may be asserted, and is claimed with some degree of plausibility, that in assuming to prevent intrastate monopolies, the Federal Government is exercising a State function. But as I understand it, this is simply the result of a policy, and flows incidentally from the right to dictate terms upon which privileges on the public domain are granted: a right with which the States can not interfere. Where a right exists, the motive with which it is exercised, in a legal sense, is of no moment. As before noted, in the initiation and administration of measures designed to carry these policies into effect, the State has no voice, and so long as the Federal Government carries out these measures without infringing on the rights of private property, which it had previously sold, there is no one to complain. If it becomes necessary to utilize, injure, or destroy private property for the use of the Federal Government in the carrying out of its policies of national conservation, the Government must condemn the land under State laws, the same as any public utility corporation would be compelled to do.

9. These generalizations are subject to an important consideration which involves that department of conservation which deals with the use of water in the running streams; that is, the reclamation of desert lands, Federal irrigation projects, and the development, transmission, and use of hydroelectric power. As to this field of activity, the State assumes a position of importance. So far as re-forestation of denuded public lands, the management of forests, the sale and disposal of timber, and the terms under which rights temporary or permanent may be acquired in public lands containing coal, oil, phosphates, or other minerals which may be included in the conservation policies, are concerned, the State has no function whatever to perform.

10. Running water is not, in the usual sense, subject to ownership. Rights are essentially usufructuary. As to the use of water flowing over the public domain, the Federal Government, at an early period of the development of the West, adopted the policy of sanctioning the appropriation of water for beneficial purposes and its diversion from the natural channels for mining, irrigating, and other industries. The policy had its inception first in recognition of local rules and customs, subsequently crystallizing into positive congressional enactments. So that it has come to pass that while the National Government through its ownership of the land has the right to use water passing over it for the benefit of the lands riparian to the stream, which right is purely relative in connection with private owners on the same stream, and has the right to insist, like any other proprietor of lands, that the State shall not deprive it of such rights, or interfere with the navigability of the streams, yet if it desires increased privileges in connection with its conservation policies, it must acquire the appropriative right, the same as an ordinary individual. In other words, the National Government is committed to the policy that as to rights to be acquired in running water, other than those inherent in the ownership of the land itself, the State laws, rules, and regulations are controlling. In this regard, the Federal Government occupies the same status as an individual, or private corporation.

11. Federal control over the potentialities in running water arises, not out of its ownership of the water, but out of its ownership of the land either over which it flows or over which it must be conducted. Taking for illustrative purposes, the hydroelectric feature of the conservation policies, while the right to use the water must be acquired under State laws, there can be no diversion or use of it on or over Government land without the consent of the United States. In this way, the Government is in a position to dictate the terms and conditions under which privileges and easements over the public domain shall be granted, and to exact something in the nature of a royalty for these privileges. The State has no concern with this; has no right to inhibit, or control it. If it be asserted that this attitude of the Government is inimical to the State's interest: that it retards development and paralyzes industries (and such assertions are made), the State can not complain. The Government is simply dealing with its own property in its own way under the authority granted by the Constitution and compact with the States. If there is to be a change in policy, it must come through appeals to Congress.

12. This brief analysis would seem to sanction the deduction that with regard to national conservation there is no 'twilight zone' in which National and State sovereignty overlap, or interlock. These two sovereignties revolve in concentric orbits without serious danger of collision or damage.

13. If I were called upon to suggest the possible duty of the State, I should say that it would lie in the direction of sympathetic co-operation, adjusting its water legislation and policy so as to coördinate with the Federal Government. Theoretically at least, it is the function of the State and not the general government, to prevent all monopolies which do not enter into interstate commerce. But as many streams are interstate, and electricity is an article of commerce which may be transmitted from one State into another, State control over the industry could not be universally effectual. State co-operation with the National Government in other lines has been brought about; for example, in the construction of a débris dam to restrain the detritus from flowing from the watershed of the torrential streams of California to the valleys below, a shattered hope of the hydraulic miner that this would enable him to resume the interdicted industry; also in dredging the Sacramento and San Joaquin rivers to improve navigation. Just what may be the attitude of the State as to sympa-

thetic co-operation in national conservation measures will depend on the Legislature, which, under our representative form of government, is supposed to express, for the time being, at least, the will of the people of the State.

14. It is quite apparent that the State is, like the general government, in control of one of the essential factors in the hydro-electric industry, which factors should be united in a common purpose. This situation in no sense involves a conflict in the exercise of sovereign powers. Each sphere of control is defined and recognized by both State and Nation. The State may emulate the example of the Government and impose conditions under which water may be appropriated and used commercially, for power purposes. And there looms up the probability of being compelled to satisfy two sovereigns instead of one, which suggests in turn, the possibility of burdensome and deterrent conditions. It would seem that in this direction there is room for discussion as to plans of coördination. These plans must be carefully worked out by those familiar with the complexities of the situation. Mere unenlightened opportunism, however well meant, will not accomplish very satisfactory results.

In other times and in other nations, the national domain has been the plaything of tyrants. In the American Commonwealth, it has fed the appetite of greed; has been preyed upon by the pillaging landgrabber and annexed by the fraudulent land pirate. That there still remains enough upon which to focalize a national sentiment, and around which to build a national hope, is due solely to those men who had the great foresight to take the initiative, and the magnificent courage to deliver the message. Among these patriotic citizens the name of him, who like Abou ben Adhem, leads all the rest, is that of the distinguished guest of the evening.

The New Randfontein Mill

A recent occurrence of note is the starting of 300 stamps in the huge mill recently erected on the Randfontein property, which claims to be the biggest reduction plant under one roof in the world. The mill has 600 stamps, supplemented by 16 tube-mills, and the necessary sand and slime plants. Taken altogether, it is an imposing structure. There are already 400 stamps on the Randfontein property, so that the new mill will bring the number of stamps available up to a thousand. It will be readily understood that to keep all these stamps supplied the ten mines in operation on the property will be fully employed, and to bring the ore reserve up to the mark some effort will be required. At present the ore reserve represents two years milling, which according to modern Rand practice is below ordinary local requirements. When all the stamps get fully at work at Randfontein, it is confidently expected that the property will be not only the premier producer of Transvaal, but also of the world.

Construction Work at Nevada Hills Mine

The Nevada Hills Mining Co., operating at Fairview, Nevada, is sinking a new shaft, erecting surface equipment, and building a 20-stamp mill and cyanidation plant. The 3-compartment shaft is being sunk between the original Nevada Hills vein on one side, and the Eagle and other existing veins on the other side. Both vein-systems are to be tapped by levels from the 600-ft. station of the new shaft. At the surface has been erected a 77-ft. steel head-frame, in close proximity to which a 150-hp. electric hoist is being placed. In each of the two hoisting compartments a 2-ton skip is to be operated, by which the material to be hoisted will be dumped into a 2-compartment bin at the top of the mill—one compartment for ore and the other for waste. Ore is to be drawn from the bin to a Hercules Blake crusher, 20 by 12 in.; the crushed ore is then to be elevated to the top of the mill, descending thence by gravity through automatic weighing machines to the sampling plant, and finally discharging into the 600-ton steel bin above the stamp-batteries. The milling processes comprise crushing in four 5-stamp batteries, of 1250-lb. stamps, table-concentration, and pulverizing in tube-mill; this is followed by cyanidation in connection with continuous agitation, decantation, and filtration, the final solution to be delivered to the zinc-dust precipitating-plant within the refinery building. The process is continuous throughout, and the cyanidation plant is to have some new features not used in general practice. The mill buildings are steel, the foundations being of reinforced concrete; the buildings are being covered with asbestos-lined corrugated iron, making them fireproof. The mill machinery, mine hoist, air-compressor, and shop machinery are to be operated by electricity, for which transformer houses are being built. The mill, which will have the capacity to treat 125 tons of ore per day, is provided with a steam-heating system, and is expected to be in operation by about June 10. The mill and mine plant were designed by J. B. Fleming, who is directing the construction work. W. H. Webber, who had charge of the property for the former company, is general manager for the present company, of which George Wingfield is president.

Low-grade gold mines are worked successfully in many parts of the world. Some of the Victorian mines in Australia have recently issued reports that are worthy of notice. The New Moon Co., Bendigo, treated 13,800 tons of quartz, assaying 4 dwt. 10 gr. per ton, for the six months, and a reduction in working costs to 15s. 1¼d. per ton, as compared with 16s. 3d. per ton for the previous term, enabled the company to pay dividends amounting to £2400. The Birthday Tunnel Co., Berringa, has been conspicuous for economical management for some years, and after a period of misfortune is just making headway again. The 24,398 tons of quartz crushed during the past six months yielded 2846 oz. of gold—an average of 2 dwt. 8 gr.—and was so handled that the company was able to reduce the bank overdraft.

Alaska and Its Needs

The Alaskan Committee of the American Mining Congress, consisting of Henry R. Harriman, John L. Steele, and Maurice D. Leehey, has presented a vigorous report, of which an abstract is printed below. The report is of especial interest at this time in view of the announced determination of the new Secretary of Interior to pay especial attention to Alaska.

Your Committee has sought to emphasize the fact, which they now report to this Congress, that Alaska is now suffering, and for the last two years has acutely suffered, not so much from a lack of adequate mining laws on the books, as from an uninformed, though well meaning, long-distance attempt to administer these laws. While the representatives of our Government have been, for the most part, intelligent and able men, they have been so restricted in authority and hampered by red tape and cumbersome regulations, that for the past two years, with a few notable exceptions (and these

Map of Alaska.

largely of the placer industry), the extensive, and largely intensive, development of Alaskan resources has been at least at a standstill. Alaska can be put in a most healthful and enviable position if she can be given a helpful administration of existing laws, in the spirit in which they were enacted. Such a policy once adopted toward Alaska, would necessarily bring with it the prompt and intelligent amending of laws which are susceptible of amendment, and the enactment of new legislation, as it may be required. The men in charge of the administration of the law should be granted needful authority to locally administer the laws which now exist, with full knowledge of the spirit and intent of that law, and questions which would not deserve serious attention of a town council, should not be referred to Washington to pursue a tedious course through various bureaus of the department, before appropriate action can be taken.

If the Federal Government and people at large desire to see Alaska develop, and her important resources made tributary to the National and commercial needs of the States, then let them pattern somewhat after the policy of the Dominion Government, which is making such marvelous strides by a policy of encouragement to settlers and prospectors, granting the local officials full authority to deal promptly and fearlessly with local conditions that arise. Let these officials understand that every proper act will be promptly approved, successful administration rewarded by promotion, and every blunder by prompt dismissal. Let our prospectors understand that our Government, like that of Canada, desires to see her resources developed along lines that will secure the greatest good for the greatest number of persons, and let capital be safeguarded, but duly warned that monopoly and commercial oppression in any form will not be tolerated, and Alaska will promptly respond by pouring her treasures into the lap of the American people.

While this Committee has been studying somewhat closely, and would have been glad to have presented to this Congress, if desired, a more technical analysis of existing laws, it is our firm belief that the vital question in Alaska at the present time is not a matter of technical construction and amendment of existing statutes, but one of high administrative policy to be adopted at this critical point in her history. This, then, is our report to the American Mining Congress: **Alaska's present need is a new administrative policy rather than additional legislation.** Let this statement be received in no sense as a reflection. Alaskans are not inclined to quarrel with the past. Their faces are set toward the future. We believe that the time has now come, with the fund of information which now for the first time is available to the Federal Government, when such a policy can be correctly announciated. A vigorous, intelligent, and helpful administration of existing laws, will early solve the present problems of the coalfields, the railroads, the forest reserves, and the fisheries of Alaska, and will indicate from time to time further legislative steps. It will be better for Alaska to be given a helpful and intelligent application of inadequate or even inappropriate laws, than to continue in the present condition.

Both the President, Mr. Taft, and Mr. Roosevelt have endorsed the general proposal of a leasing system for coal lands. We recognize the popular demand at this time for some such system, and are not opposed to its adoption, if it can be made uniformly applicable to unappropriated coal lands throughout the United States as well as Alaska. There are now in Alaska, unappropriated and reserved by executive order, 1000 out of 1200 square miles of known coal area, as distinguished from large districts which have not been visited by the prospector, and that there are within the United States, exclusive of Alaska, according to the report of the President, 95,515,000 acres of coal lands now withdrawn by executive order. A general leasing plan, therefore, if brought to a successful solution, would be applicable to 80% and we believe fully 90% of the known coal lands in Alaska.

The belief seems to have gained ground that Alaskans have objected to a leasing plan for the reason

that they do not wish to subject the coal to a fixed royalty, or tax, per ton. This is not in any sense the case. Not only have the Alaskans no objections to the imposition of a reasonable tax per ton upon coal exported, but they have gone so far as to publicly suggest such a fixed revenue, on condition, however, that the proceeds be applied to the construction of needful roads in the mining districts, the building of school houses and other expenditures in Alaska. We have found a well-rooted objection to taxing the products of Alaska for the benefit of the States, and it would seem that this objection is well grounded in the principles of true conservation in the opening up of a new country.

For two years this Committee has conducted hearings and personal investigations, and has been made intimately conversant with a large majority of pending coal entries in Alaska. The claimants have spent in the aggregate fully a million and a half dollars and years of effort in prospecting and developing the coal resources of Alaska. They are for the most part men of moderate means, and they are entitled to be given the patents which the law of the location promised. There should be reasonable restrictions, of course, but the present claimants should be given such title as will enable them to raise the necessary development funds by selling bonds based upon their title. Of the million and a half dollars which we estimate has been so raised and expended by these men, and their friends and associates in the States who have backed their efforts, we do not include a single dollar coming from any source which could in any way be criticized or made a subject of suspicion or innuendo.

In ascertaining the sentiment of Alaskans on the proposed leasing system, the Committee has been surprised to find that those interests which have in the past been freely charged with a desire to monopolize the coal lands of Alaska, are today fostering, and in some cases advocating, the adoption of a leasing system. This Committee is in no way opposed to any of the interests operating in Alaska. We believe that the investment of large capital should be encouraged. It is, however, a fact, that for the last fifteen or sixteen months the leasing plan has been openly favored by certain of these interests. Human nature and the desires of 'big business' are sometimes selfish, and we sound a note of warning lest, taking advantage of a present popular clamor for the leasing system, and with less expense to themselves, by ignoring the rights of the discoverers, a monopoly of production of the Alaska coalfields may not be more readily brought about under a leasing system than by a rigid enforcement of the anti-monopoly clause of the Act approved May 28, 1908. We submit, that to force at least a large number of Alaska coal claimants to accept leases to the lands to which the law entitles them to receive patent, will absolutely confiscate their holdings. And further, if they, the men of Alaska, be eliminated, your Committee is firmly convinced that the result will be to give the control of the Alaska coalfields to the transportation companies and their proteges, and that such companies, now existing, and yet to be formed, without being obliged to recompense or reimburse the men who have discovered and opened up these fields, will be able to effect a monopoly of production of the Alaska coalfields, more sweeping and ironclad than would be possible under a rigid but helpful enforcement of the Act of May 28, 1908.

We find that Alaskans generally are endorsing the recommendation of the President and of the Secretary of the Interior for the creation of a Land Court. They have come to recognize this as the proper method for the determination of contests to which the Government is a party. The officers of the General Land Office should no longer be forced to act in the treble rôle of detective, prosecutor, and judge. We submit that the claimants to Alaska coal lands and mineral lands are entitled to have their rights determined as speedily as possible, and by an impartial tribunal. The proposed Land Court could promptly distinguish between valid and fraudulent entries, and do justice to the claimants, and at the same time provide a fuel supply for Alaska, the Pacific Coast, and the American Navy.

A percentage of the Government Agents who have been called upon to make important reports upon Alaskan matters have actually visited, in Alaska, the subject-matter of their reports. We write it down as an axiom that wherever an agent of the Government has actually visited in Alaska, the subject of his investigations, be it coal, fisheries, or otherwise, has met on the ground the men whose business he was inspecting, and has informed himself as to the actual facts and conditions surrounding the case, that his report has been broad and liberal in its character, and helpful in its results. On the other hand, the reports which have handicapped and injured Alaskans, and which are largely responsible for current misinformation on Alaskan subjects, have been written in the 'wilds' of Seattle, and amplified by men who have braved the hardships of Washington, D. C.

Recommendations.—(1) The new policy, and the helpful and intelligent enforcement and amplification of present laws, including the law intended, as its title states, 'To encourage the development of coal deposits in Alaska.' To aid in this, we believe in the creation of a Land Court, as proposed. We believe that such a tribunal can determine these questions uninfluenced by popular clamor, and its decisions will be readily adopted by the people at large. (2) We feel that the most urgent demand of Alaska is for the opening of her coal properties. While, unquestionably, transportation throughout Alaska is the greatest present necessity for the mining industry, coal must be provided before we have the transportation facilities. (3) No policy for the development of Alaska will be well founded or can long endure which does not recognize as an essential principle the rights of the discoverer and of the pioneer; that while Alaska invites, and must make attractive, the investment of large capital, she must at the same time make an equal appeal to and equally safeguard and encourage the pioneer and prospector.

El Oro Steel Spud

The problem of making a spud that will stand the heavy strains incident to dredging in hard ground is one that is extremely diffieult to solve. The first spuds were sticks of wood. These long since proved inadequate, and are now only used on the smaller boats or for stepping ahead. Spuds built up of structural steel have been in use in California for some years. As the size of the boats

built has increased, the problem of building from stock material has had to be abandoned, and now specially rolled plates and beams are demanded.

In general, spuds are now made of steel beams set side by side and covered by plates. The whole is riveted together, and a possible element of weakness is that it has been customary to use many small rivets; this necessarily involving many holes in the plates. A spud of this construction is exceedingly difficult to repair, since there is no opportunity to work inside, and it must be torn to pieces. W. S. Noyes of the El Oro Dredging Co. has recently designed a box spud. The accompanying figures show the construction in such detail that but a few additional words are necessary. In making this

spud heavy plates and relatively few units were used, and the centre is left clear except for bulkheads, as shown. The steel point is round for a distance of 8 ft. up; rather more than the usual height. Since the point is buried in the mud, it is obvious that it must be round to reduce torsional strains as the boat swings. Indeed, a round spud would have advantages in this connection, but it would impose difficulties in regard to guides and

wearing surfaces. Where the steel point and the plates join, the contact surfaces were carefully machined and every precaution has been taken to secure an exact fit. This spud was built at the Indiana machine-shops from plates furnished by Cambria Steel Co. An interesting incident in connection with its construction was the first use of an oxy-acetylene blow-pipe in the California dredging fields. A long flaw being discovered in one of the cover plates, the blow-pipe was called into service and melted a strip of new metal into the plate with surprising speed and success.

MINERAL LANDS CLASSIFIED

During January 470,664 acres of public land was appraised as coal land by the U. S. Geological Survey, at a value of $10,835,848, and 447,383 acres was classified as non-coal land, making a total coal appraisement of 14,119,447 acres, valued at $635,959,358, and a total non-coal classification of 34,298,900 acres. At the minimum price allowed by law, the price the lands would have brought but for this appraisal, the lands thus far classified as coal land would have a value of only $216,960,426. The 470,664 acres of coal land appraised during the month, valued at $10,835,848, and restored to entry, would have brought at the minimum price only $5,621,532, involving a loss to the Government of $5,214,316. One coal-land withdrawal of 468,107 acres was made during the month in Colorado, and five restorations were made in Colorado, Montana, New Mexico, Utah, and Wyoming, aggregating 1,369,849 acres. The total area withdrawn as coal land on February 1 was 80,547,481 acres. Two withdrawals of oil land were made during the month, with a total area of 392,154 acres, and one restoration of 189,710 acres.

Simple Methods of Making Ditch Surveys

By JAMES W. PHILLIPS

*The first miners were gravel-miners. They put in ditches to carry the required water, though few, if any, knew how to figure the flow of water. A crude method of measuring water flowing through orifices under a head was developed, and the amount of water was the area in square inches of the orifice, regardless of its shape. The gravel-miner wanted to get water to the place where it was needed, and the possibility of washing the ground away was the only thing that prevented him from running his ditches in a straight line if possible, instead of following a grade. In many instances tunnels were cut and straight flumes put across valleys. Following the first miners, and practically at the commencement of the hydraulic-mining era, there followed a generation of men, many of them surveyors and engineers, who used the following adaptation of the Eytelwein formula for open ditches:

$$v = \sqrt{(9000\ rs + 0.012)} - 0.11$$

or the following adaptation of the Poncelot formula

$$v = \sqrt{\left(\frac{9000\ as}{p}\right)} - 0.11$$

and for pipes the following adaptations of the Hawksley and Poucelot formulas:

$$v = 48\sqrt{\frac{dh}{1 + 54d}}$$

in which v = mean velocity in feet per second; a = area of cross-section of water, in feet; p = wetted perimeter in feet; r = hydraulic mean radius in feet = a ÷ p; s = sine of slope = h ÷ l; h = fall in feet in any length; l total length in feet on the slope; d = diameter of pipe in feet.

The foregoing formulas were printed in many handbooks given away by firms dealing in tools and machinery used by miners, and also in miners' pocket-books. They seldom appeared, however, in the forms here given, but were painfully expressed in words like rules in arithmetic, with worked-out examples. They were used by a great many men who would have been scared by the sight of a formula. A tremendous amount of practical data has been stored in the heads and notebooks of the older miners, but the engineer of experience in this line of work is better equipped than the practical man without scientific education.

As the mines grew larger, and the operations were conducted on a mammoth scale, the engineer was employed to run the ditch-lines and do all the work that called for education and skill in the handling of water. When the larger mines were finally shut down by the court, a large number of engineers had to seek other employment, and many of them engaged in irrigation, but found it hard to come down from grades of 10 ft. to the mile to that

*Abstract from 'Hydr[illegible] Auriferous Gravels,' *Jour.* West. Soc. Engi[illegible]

many inches sometimes. The classic experiments of Hamilton Smith on the flow of water in pipes were made for hydraulic miners, and the engineers employed from early in the '70s to the time the work was stopped were men of whom the State might well be proud, and were a credit to their great profession. With the engineers employed by the larger companies, as with the engineers employed today, the favored formula has been the Chezy; that is,

$$v = C\sqrt{rs}$$

with the factor C computed by the Kutter formula, or the following modification of it, which is close enough for practically all use:

$$C = \frac{42 + \frac{2}{n}}{1 + \frac{42n}{\sqrt{r}}}$$

using the following values of n: planed boards, n = 0.010; common boards, n = 0.012; rubble, n = 0.017; earth, n = 0.025.

In surveying for a line, flumes and abrupt turns should be avoided wherever possible. It is always well to hit a hill hard in going around a point, so there will be a good outer embankment. There should be a good roadway along all ditches, and on the lower side all obstructions, bushes, etc., should be removed in order that the lower bank, made by fill, will be solid. A number of hints might be given, but they are all summed up by saying that the ditch should be in as firm ground as possible and constructed so it will not destroy itself.

Many of the older generation of miners have damaged the appearance of much of the country because of the steep grades on their ditches, and many abandoned ditches have become ravines. The modern engineer and ditch-builder pays some attention to the character of the material through which the ditch runs. Careful attention to the following table of safe velocities, given by Sir John Neville in his Hydraulic Tables, is recommended for mean velocities:

0.42	feet	per	second	in	soft alluvial deposits.
0.67	"	"	"	"	clayey soils.
1.00	"	"	"	"	sandy and silty beds.
2.00	"	"	"	"	gravelly earth.
3.00	"	"	"	"	strong gravelly shingle.
4.00	"	"	"	"	shingly soil.
5.00	"	"	"	"	shingly and rocky.
6.67	"	"	"	and over, in rock.	

A limit of about 15 ft. per sec. is set for first-class masonry and wood, the bottom velocity being about two-thirds to three-quarters the mean velocity. The Dubuat formula for bottom velocity is as follows:

$$v_b = v\,11\sqrt{rs}$$

in which v_b = bottom velocity in feet per second; v = mean velocity in feet per second; r = mean hydraulic radius; s = sine of the slope.

In the reconstruction of these old ditches to meet the requirements of hydraulic mining, I have always had to [illegible] observance of the character of the material through which the ditch runs, and a careful stepping down of the grade at intervals of from one-eighth to one-fourth of a mile, would reduce the initial cost of construction as well as of maintenance. Throughout this section a grade of 6 to 12 ft. to the mile is as much as should be used.

The pioneer miners were a resourceful body of men, and many difficult problems were solved by them in the construction of their tunnels, ditches, and other engineering works of magnitude. Miles of ditch-grades were run with only a buckskin thong with a rock tied to it for a plummet, attached to the apex of an A-frame made of three small spruce poles. I remember, when, as a lad of eight years of age, I drove grade-pegs upon a ditch-survey run by my father, assisted by my brother, through five miles of the roughest country in northern California, with one of these 'instruments of precision', and how in veneration I stood upon the brink of a deep canyon, the precipitous sides of which precluded a measurement with chain or tape, and witnessed the chief of party triangulate the distance across with accuracy and dispatch, and establish the grade with this simple contrivance with as much ease as the present day engineer would accomplish it with his transit and stadia, or with the gradienter attachment.

The A-frame is made as follows: Construct with any light material an A-frame with the legs extending 2 ft. below the cross-bar, and having a span of from 10 to 12 ft.; at the apex drive a nail and hang a plumb-bob from it with line sufficient to permit the plumb-bob to hang below the cross-bar. This instrument is adjusted over two pegs as follows: Drive two pegs in the ground at a distance apart equal to the distance spanned by the legs of the frame; place the frame upon the pegs and note the position of the plumb-line at the cross-bar; reverse the frame and note the second position of the plumb-line between the two positions already noted, and drive the highest peg down until the plumb-line covers this midway mark on the cross-bar; the tops of the two pegs will then be at the same elevation. Several methods are used for graduating the cross-bar to permit of grades being run, and one method is to rest the ends of both legs on the pegs after their tops have been brought to a level. Then one man at one end will raise the leg he holds to certain heights measured on a rule he holds on the peg, while another man will mark the position the string occupies on the cross-bar and will mark it on the grade. Thus falls of 1/16, 1/8, 1/4, etc., of an inch per station will be obtained, the stations being equal to the spread of the triangle, or base of the A-frame. It is not claimed that the A-frame originated among the pioneer miners of California, but it was used by them to lay out some of the longest ditches and tunnels constructed in the early days of mining in that State.

Borax is used in the enameling industry for making kitchen and sanitary ware, about one-half of the output being so used.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Arizona Copper Belt M. Co.

The Editor:

Sir—In the prospectus of 'The Arizona Copper Belt Mining Company' of Wickenburg, Arizona, there is a sheet containing a wholly unauthorized letter over my signature; I have never been in Arizona, much less examined any properties there. The whole appears to me to be a very scurvy trick of what is probably a 'wild-cat' company, and if it is allowed to pass unnoticed, may react seriously against me. In a letter to the president of the above company, I have demanded that the objectionable letter be withdrawn, and, as one of your subscribers, I shall consider it a great favor if through your columns you can help me refute their false statement.

R. W. GROO.

Bingham Canyon, Utah, March 26.

Suppressing a Government Report

The Editor:

Sir—In connection with the subject to which attention was drawn by Louis Lane in your issue of March 4 and in addition to your own comment thereon, it may be well to record a few additional facts.

When field-work was done in the Bullfrog district by the geologists of the U. S. Geological Survey in the winter of 1905-6, permission to examine the Montgomery-Shoshone mine was refused, and this unusual attitude on the part of a mine's owners was noted in the preliminary account of the district published in 1907 (Bull. U. S. Geol. Survey No. 303, p. 52). Anyone contemplating the purchase of stock in the mine might have drawn the obvious conclusion from this refusal and been warned in time. In March, 1908, Henry Krumb made a report on the condition of the mine. His results, which were decidedly unfavorable, were not only printed, but were widely commented upon in the mining journals. Here again, one might have supposed, would have been ample warning for the intending investor. It was not until July 1908 that opportunity to study the Montgomery-Shoshone mine was granted to a Government geologist, and the final report on the district appeared as U. S. Geological Survey Bulletin No. 407, early in 1910, the interval of time between the completion of field-work and the publication of the report being shorter than is generally required for the preparation and the publication, through the Government Printing Office, of an illustrated scientific report that must take its turn with many others. Finally, as is very truly suggested in your comment, the Government geologist who sought access to mines in order to evaluate them or to cry prompt warnings to investors would soon find himself barred out from his field of activity. The fact that a geologist of the Federal survey can almost invariably secure free access to a mine is due to the confidence of the owners that the objects sought are chiefly scientific, that the data obtained will be used in reaching conclusions of value to science and to the district as a whole, and that information imparted and received in confidence will not be divulged. The owners know, too, that although the geologist will not connive at misrepresentation, he will not go out of his way, on the other hand, to pass judgment on management or finance.

F. L. RANSOME.

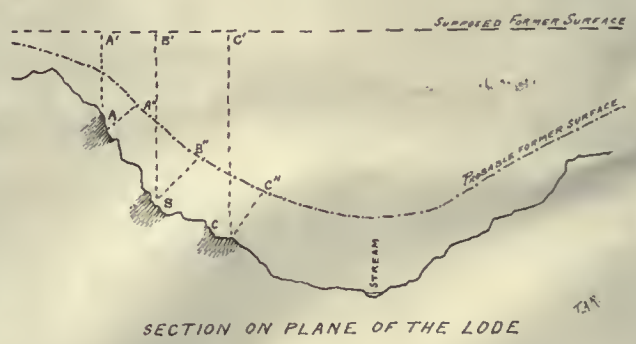
Washington, March 9.

Ore-Shoots

The Editor:

Sir—I have just been reading the suggestive article by Mr. W. H. Storms in your issue of October 22. My discussion of it may seem belated, but you will, I trust, deem the perennial interest of the subject sufficient to warrant the publication of even these late remarks.

In that article Mr. Storms draws upon his wide experience among the mines of the Mother Lode, in California, and lays stress on the inference to be drawn when a gulch is seen to cross the strike



SECTION ON PLANE OF THE LODE

of a vein. He argues that such a depression in the surface indicates the existence of disturbed ground likely to terminate an orebody. Hence if you are following an orebody you may find it die out or end abruptly at the fault whose zone of shattered rock gave erosion the chance to make a gulch. But if you look at the occurrence from the opposite side of the supposed gulch and you are prospecting a promising vein that yet does not carry any continuous orebody, then, on reaching the fault, you may hope for more favorable conditions on the other side of it, and, provided the faulting is not so confusing as to make it impossible to trace the vein on the far side, you proceed more hopefully to search for ore beyond the fault. Speaking broadly, we may say that no rules will fit all cases, because the study of ore deposits has not yet reached the dignity of an exact science, but such suggestions as Mr. Storms offers are of the greatest value in stimulating intelligent observation. To the mine superintendent any change of rock or structure is unwelcome when he is in pay-ore, and conversely any change will seem promising when his drift is in barren ground. Old miners have

fancies, for which they can give no reasons, but that are nevertheless the expression of a life-long experience. It is a rule-of-thumb ratiocination, but it is well worthy of respect. Thus the idea that water is a good sign is confirmed by scientific reasoning. Most ore deposits are formed by the action of water circulating along the clefts, fractures, and fissures made by earth-movements. Water was the medium of migration whereby the valuable metals have been concentrated in orebodies. The presence of water in a vein suggests a favorable agent. Where the rock is so hard and tight as to prevent the passage of ground-water, it is likely to have been similarly opposed to the free circulation of thermal waters at an earlier period. Moreover, when the workings of a mine continue to be wet to a great depth, it argues the existence of fairly open ground and conditions favoring the passage of descending waters, which, in many cases, are the agents of secondary enrichment. The Butte lodes, with their chalcocite at 2000 feet in depth, constitute a remarkable example. When, on the other hand, a lode becomes so dry as to be dusty when broken, the condition is unfavorable to persistence of ore, and particularly to such secondary enrichment as is due to descending waters. A mine that is dusty is below the zone of ground-water and therefore beneath the horizon in which chemical interchanges have free scope. Another fancy of the miner is, as Mr. Storms says, a fondness for a vein that has a gouge streak. Gouge is clay or rock crushed to a clay-like consistence. It is the product of movement and the accompaniment of faulting. Apart from its testimony to a line of weakness and a plane of dislocation, the gouge serves as a barrier to the free passage of waters, either those of today or those that may have deposited the ore. This means that the impregnation of the rock encasing a water-way is limited or restricted by the gouge, so that enrichment is prevented from being spread over too great a width. To the miner the intensity of mineral concentration by Nature measures the difference between pay-ore and worthless rock.

Before closing I venture to offer an observation, the correctness of which I have tested in many mining regions. It is this: Depth of ore deposition is not to be measured from an imaginary horizontal former surface, but from a line approximating that of the present-day contour. For example, if ore is found at A, B, and C, it should not be assumed that these represent the stumps of ore-shoots that, before erosion, extended to A′, B′, and C′, the three equivalent points on the horizontal surface of a remote geological period. On the contrary, I would measure the persistence of the ore from a former surface not much unlike that of today, as at A″, B″, and C″: in other words, I would infer that the concentration of mineral now constituting an orebody has been effected in late time and in a period during which the contour of the surface was possibly different from that of today but not wholly unlike. Therefore, I would measure persistence at right angles to the surface of the hill. I would not argue because the ore at C is 500 feet lower than at A, that therefore the orebody A will continue at least as deeply as the level of C. On the contrary, I would hasten to ascertain whether the orebodies extended into the mountain, as measured from its slope, and until I had proved that they did so I would be sceptical, believing that the enrichment is associated with conditions that exist to their maximum degree near the surface. An example in point is afforded by the silver-lead veins of Grand Clos, in the Hautes Alpes, France. There ancient workings disclosed several parellel lodes in which a series of orebodies had been stoped for a short distance into the steep side of a canyon. The faces of the stopes showed ore, which, I believe, was poorer than that previously extracted. An English company was formed to work these mines, and all went well for a short time, but the grade of the ore decreased as the stopes penetrated the mountain; finally, the yield becoming below the economic limit, all work was stopped. In this case the evidence amply corroborated the idea that the enrichment diminished in a line at right angles to the present surface, and not vertically. This note may prove suggestive. Personally, I have always demurred strongly to the inference, common in flamboyant prospectuses, that because some rich ore is found at the bottom of a hill and some more near the top of it, this proves the continuity of the ore for a depth measured by the difference of altitude.

T. A. Rickard.

London, March 15.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—In the issue of the *Mining and Scientific Press* of February 18, R. P. McLaughlin, in referring to the influence of gulches crossing ore-shoots, says, "Concerning the supposed rule of ore-shoots in relation to gulches, which generally has failed of application at the various mines and prospects that have been under my observation," etc. Mr. McLaughlin would confer a great favor upon all of us if he would kindly state the whereabouts of the exceptions to the "rules." A number of engineers and geologists have questioned the correctness of my theory, but with a single exception, that of Charles Janin, none of them have attempted to state where the exceptions of which they have knowledge may be found. In previous communications on this subject I have given numerous instances where ore-shoots terminate upon reaching a gulch or depression at the surface, and I think it but fair to those interested in the discussion for any who disagree with my "theory" to state where these exceptions may be found, that all may be better able to determine the important question, whether the "rules" have wide application, or whether, when an instance is found which fits the "theory," it is merely a coincidence.

William H. Storms.

Berkeley, California, February 22.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Silver added to gold in small amount forms a green alloy which is employed by manufacturing jewelers.

Copper-matte can be successfully made in either blast-furnaces or in reverberatories. The latter type of furnace is generally used for the treatment of fine ore and concentrate.

Burning oil, gasoline, alcohol, or other burning liquid should be extinguished with sand, soil, or even flour. Never throw water on a blazing liquid, for it is likely to cause the flames to spread.

Black manganese oxide has a market value if the cost of mining it and getting it to market is not greater than it will sell for. First-class ore is worth about $10 per ton at San Francisco, California.

Potash may be derived from organic sources, as from wood ashes and sea weed. The giant sea weeds of the California coast contain potash salts, but no experiments have yet been made to recover them on a commercial scale.

Copper sulphate in water in small quantity will destroy organic matter in it. Reservoirs that have become foul by growth of algae and other organisms have been purified by means of a weak solution of copper sulphate.

Outcrops of siliceous iron ores which show no sign of copper at the surface sometimes develop into valuable mines. The Iron Mountain copper mine of Shasta county, California, was one of that kind. The siliceous iron outcrop was first worked for silver, no copper being seen in the ore.

Oro City was the original name of the camp where Leadville now stands. It was a rich placer-mining district twenty years before it became famous as a silver camp. The present outlook is that Leadville will have many more years of profitable existence. It has been an important producer of silver, lead, and zinc ores since 1877.

A patent was obtained by W. D. Johnston in 1893 for the use of barium peroxide as an accelerator in the dissolution of gold in cyanide solutions. The process never became popular for the reason that other and less expensive methods of accomplishing this were introduced, among them being agitation by compressed air.

Abandonment of water rights has been defined by the Supreme Court of California, which has held that "the failure on the part of A to make any beneficial use of water for a period of more than five years next preceding the commencement of an action by B claiming adverse rights, results in the forfeiture of A's rights held by appropriation."

Innovation in underground methods has been as much a feature of mining practice the past few years as the numerous changes in metallurgical treatment of ores. The methods which a few years ago were considered the best, as indeed they were, have been abandoned in some districts for those that are newer and better, because less expensive, safer, and in some cases easier than the old methods.

Side-marks on the reels of hoisting-engines are the only safe indication of the position of the cage or skip in the shaft. No hoisting engineer will trust wholly to the needle of the indicators which form a part of most hoisting outfits, being operated by gearing; for these are only roughly approximate at best, a small fraction of an inch on the indicator equaling a foot or more in the shaft. Serious accidents have resulted from failure to provide side-marks on the hoisting-reels, which indicate accurately the position of the skip.

White-lead (lead carbonate), may be precipitated from a solution of sodium hyposulphite containing lead by means of soda-ash, the lead falling as a flocculent white precipitate. When the lead has completely settled the solution may be decanted to another tank, and if it contain silver it may also be recovered by addition of either sodium or calcium sulphide, which throws down the silver as sulphide. The refining of this precipitate is often a most difficult metallurgical operation, and when such is found to be the case it is the better plan to ship the silver sulphide, after drying, to a refinery. It will be found more economical to do so.

Chuckblocks in stamp-mills are intended to keep the height of discharge as nearly uniform as possible, the principal object being to prevent sliming of the ore. Where sliming is objectionable, those ores which have a natural tendency to slime should be crushed with the use of chuckblocks. As the die wears down, the high chuckblock is replaced by a lower one, thus preventing to some extent the sliming which would take place if the change were not made. In some mills the chuckblock has a copper plate attached to its inner edge; in others it is fixed to a permanent block inserted below the chuckblock. The former practice is generally considered the better.

Amalgamation-plates in front of a stamp-battery should be free from the jar and vibration due to the falling stamps, as the shock appears to have a tendency to disintegrate the amalgam, thereby causing loss. It has been demonstrated, however, that an amalgamated copper-plate on a Gilpin county 'bumping-table', or on a vanner, from which the belt has been removed, will hold passing particles of gold better than a plate that is stationary. In the latter case the machine was given the usual vibratory movements, only the 'travel' being out of use. A small piece of copper plate placed on the spreader of a vanner directly beneath the feed-pipe, will accumulate gold if there is any present, and free, in the pulp.

THE MINES COMPANY OF AMERICA

The Mines Company of America, which operates the Dolores, El Rayo, Creston, and La Dura mines, in Chihuahua and Sonora, Mexico, made an operating profit on each property for 1910, as follows: Dolores, $423,943; El Rayo, $374,267; Creston, $218,294; La Dura, $41,329, making a total operating profit of $1,057,834 from the four mines. After deducting general expenses, there remained a total net profit of $1,012,898. There was effected during the year a noteworthy reduction in operating costs. Those of Dolores were reduced from $15.57 per ton in 1909 to $12.58 per ton in 1910. El Rayo costs decreased from $10.21 per ton in 1908 to $6.23 in 1910; Creston costs fell from $5.91 to $4.74. By the use of additional equipment now being provided at the different properties, a still further reduction in costs is anticipated. The estimated valuations of the ore reserves of the four mines are as follows: Dolores, $1,875,288; El Rayo, $889,300; Creston, $1,750,860; La Dura, $1,108,060. The operations and development of these properties are under direction of George A. Schroter, consulting engineer.

PHOSPHATE ROCK IN MONTANA

Mention was recently made of the discovery of beds of phosphate rock on the Oregon Short Line railway, about 30 miles southwest of Butte, Montana. Analyses of samples from these deposits show the material to be of good grade, and the evidence obtained indicates its occurrence in beds of commercial quantity. The deposits are described as resembling those of the southwestern Idaho and western Wyoming fields, from which phosphate has been shipped for several years. The nearness of the phosphate beds to the Washoe smelter at Anaconda, where sulphide ores are reduced, is important, for the smelter produces great quantities of sulphurous acid fume which now goes to waste through the smokestack. As is known throughout the country, the ranchers and some experts have contended that such fume destroys vegetation and is a detriment to the raising of cattle; and it was sought to compel the smelting company to condense or otherwise dispose of the acid fume. Now a use is found for the sulphuric acid. The reduction of the phosphate rock by means of the acid would be a means of utilizing what has long been a waste product at the smelter.

TWO NEW COPPER PRODUCERS

Much attention is focused upon the two Arizona copper properties which last month started their new concentrators and began their records as producers. The Miami, situated in the Globe district, has a normal mill capacity of 2000 tons of ore per day, and is operating on ore that assays about an average of 2.65% copper. The concentrate product is to be smelted at the plant of the Cananea Consolidated Copper Co. at Cananea, Sonora. It is estimated that there will be a recovery of 35 lb. of copper per ton of ore, at a cost of 9c. per pound. The estimated Miami ore reserves are given at 20,000,000 tons, and the prospective annual production of copper is 40,000,000 lb. It is probable that the mill can be operated in excess of its rated capacity. The Ray Consolidated, having an estimated reserve of 80,000,000 tons of copper ore in its mines at Ray, near Kelvin, has a mill capacity of 6000 tons per day, and it is probable that this can be exceeded. The Ray mill and power-plant are at Hayden, situated on the Gila river, a short distance east of Kelvin. This company must bear the expense of transporting its ore 15 to 18 miles, which is the distance from Ray to Hayden. However, it is not intended that its concentrate shall be shipped, as the Ray company is engaged in building a smelting plant in close proximity to its mill. Ray ores, according to sampling and assaying, have a copper content of 2.17%, and the estimated extraction of copper is given at 34½ lb. per ton of ore. The prospective output is estimated at 100,000,000 lb. of copper per annum at a cost of 8½c. per pound. The plants of the two companies began operating at about the same time, and have hardly reached their rated capacities as soon as this, though both mills are reported as operating satisfactorily. The copper turned out by the Ray company will be marketed by the Guggenheims under a favorable contract; that of the Miami company will be handled by the Amalgamated company, which is considered to have control of the United Metals Selling Co. Both companies have plans matured for building additional mill units, and greatly increasing the capacity of each plant.

THE NEW ALVARADO MILL

The Alvarado Mining & Milling Co., owner of the Palmilla mine, situated three miles from Parral, Chihuahua, has completed and put in operation its 60-stamp mill and cyanide plant, and we give herein a brief description of the equipment and its arrangement. The mill and power-plant are separated from the mine by several thousand feet, requiring the use of a surface gravity tram-line, and an aerial tramway for conveying the ore from the mine to the mill. The ore is carried over the surface tramway in 5-ton cars which are discharged into loading-bins at the nearest terminal of the aerial line of buckets, the latter having the capacity to deliver ore at the mill-bins at the rate of 30 to 40 tons per hour. The ore is discharged by gravity from the receiving bins, passing over six grizzlies to three 9 by 15-ft. Blake crushers, thence by plunger feeders to three 19-in. belt-conveyors, the latter delivering the crushed ore to three battery-bins, each of 800 tons capacity. The ore passes from these bins by gravity through Challenge feeders to the twelve 5-stamp batteries, the mortars being of the El Oro type, and the stamps of 1160 lb. each. Each battery is driven by a 30-hp. motor, and the stamps make 102 drops per minute. The mortars are set on a concrete foundation extending the length of the battery floor. The pulp discharged from the mortars is passed through cone-classifiers to Deister sand-tables, the tailing from the latter passing to four Dorr classifiers which separate sand from slime. The sand product of the Dorr machines is then pulverized in four 5 by 22-ft. tube-mills; the tube-mill pulp is carried by three 10-in. bucket-elevators to three cone-classifiers, the oversize being returned to the Dorr machines for reclassification, the slime passing to Deister slime-tables, by which it is re-concentrated. The tailing from the slimer is then passed to six dewatering cones, each 16 by 18 ft., the clear water flowing to two 15 by 30-ft. tanks, and is pumped thence to storage-tanks for use in the batteries again. The slime from the dewatering cones is pumped to Pachuca tanks, of which there are 12, each being 15 ft. diam., and 47 ft. deep. After the aeration and cyanidation takes place in the Pachuca tanks, the slime is passed to Butters filters of 180 leaves, divided into two sections, each section having three hoppers, with a 13 by 13-in. Wheeler discharge valve for each hopper, through which the clear solution passes to the precipitating department.

The power-plant contains five Babcock & Wilcox water-tube boilers, each of 250 hp.; a Nordberg cross-compound, two-stage air-compressor, with the capacity to deliver 1800 cu. ft. of free air per minute; four cross-compound Corliss engines, three of which are direct-connected to that number of Allis-Chalmers generators. Each generator is a 3-phase, 480-volt, 600-ampere, 60-cycle machine. The electrical equipment, including transformers, providing for the delivery of power to all parts of the mill and to the Palmilla mine, is the most complete that can be devised. The Allis-Chalmers Co. supplied the generators and electrical equipment, while the Minneapolis Steel & Machinery Co. constructed the power-plant. The Alvarado M. & M. Co. is under the management of John I. Long of Parral. The mill was designed by Bernard MacDonald, consulting engineer for the company. The construction work of the mill was under direction of T. H. Gracey.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

Gold Production for January.—Associated Mine.—Bullfinch Sampled.—Golden Horse-Shoe Mill.—Boulder Perseverance.—Automatic Pulp-Distributers.

The January gold output of Western Australia was valued at $2,535,000, some $165,000 less than the yield for the same month of 1910, while dividends amounted to $490,000, against $560,000. Development and general work has proceeded along the following lines: The contemplated shut-down of the Associated for a month to re-skid the main shaft and overhaul the mill has taken place. The shaft was fitted with jarrah skids 6 by 3½ in. for 2000 ft. in depth in a little over two weeks, working three shifts with two men in each of four gigs, and four winches. Skips to hold about two tons each are being made at the mine, and should soon be finished. Advantage was taken of the shut-down to do a little development work and fill up stopes from the waste dump. The main hoist was overhauled, as was also the mill engine and condensing plant; while the low-pressure turbo-generator was completed along with its new switchboard. The new No. 7½ type K, Gates crusher is ready, and the milling, roasting, grinding, and treatment departments were thoroughly overhauled. Motors are installed for driving every part, there being over thirty of them. The new plant has been started, and so far is doing well, the usual little adjustments being necessary. Treatment costs should eventually drop to $2.40 per ton. At the No. 7 level of the Associated Northern, the company has been diamond-drilling east and west, but without cutting profitable ore.

The Bullfinch has been thoroughly sampled by the management, with the following interesting results, although no estimates of reserves are announced: No. 1 shaft: average 7 ft. worth $172 per ton, with rich ore on each side; the west drift at 100 ft. is in 73 ft., averaging 9 ft. 3 in., assaying $250 per ton; good ore in the end and average value of $172 per ton for whole drift. No. 2 shaft: at 60 ft. average width 8½ ft., worth $77 per ton, with good ore on each side; lode 21 ft. wide at 67-ft. depth. Water shaft, 275 ft. southeast of No. 1: from sinking on crosscut and short drift, width 16 ft., worth $26 per ton at 60-ft. depth; now sinking in good ore, which is supposed to be a continuation of the main lode at No. 1 shaft. The prospecting shaft 500 ft. west of No. 1 is being sunk in ironstone ore at 23 ft., worth $11 per ton. It is a large body and is improving with depth. Work on the other lodes in an ore channel 200 ft. wide is not sufficiently advanced, but is promising. In connection with the notorious Chaffinch mine, the late manager and two Melbourne mining men have been charged with conspiracy to defraud the public. It is a peculiar business, and at present one fails to see how the charge is to be proved. The railway is now open to the Bullfinch field; so, within about three months, the field has been provided with the telegraph, railroad, and water supply. The last commodity is being sold now at $1.20 per 100 gal., rather a difference from the former price of $7.20 per 100. The Golden Horse-Shoe has its new milling plant at work, comprising 170 stamps, more Wilfleys, tubes, and pans, and a tailing-wheel 60 ft. diameter. The Great Boulder Perseverance is gradually increasing its profit, although only treating $6.45 ore. It is a great pity that the Great Boulder is not able to find any length of payable ore at 2800 ft. It is not for the want of energetic exploration by drill, driving, and cross-cutting. The South Kalgurli has opened ore at 1500 ft., and work at 1800 ft. is in progress. The affairs of one of our former big producers, the Westralia Mt. Morgans, 180 miles northeast from Kalgoorlie, are being wound up. Development work has failed to reveal more ore. To date 588,880 tons of ore has yielded $6,340,000; and $1,500,000 has been paid in dividends. A modern 60-stamp mill, of 1600-lb. stamps, and a complete cyanide plant ran successfully.

In the January *Journal of the Chamber of Mines*, W. R. Degenhardt discusses the automatic pulp-distributers in use at the Sons of Gwalia and Lake View & Star, for feeding pans and Wilfley tables in those mills. In the main, they consist of distributers which equally divide the pulp into as many launders as there are pans. I have had experience in feeding pans from mixers, from which a pipe ran to each pan, and the feed was even; but with mixers discharging direct into a launder with a gate for each pan, the result was very unsatisfactory. An interesting distributer at the Bunker Hill & Sullivan mill was described by Gelasio Caetani in *The Mining Magazine;* and the Kiddy distributer was described recently in *The Engineering and Mining Journal.*

NEW YORK

Interest in Porcupine. — Concentration of Copper Refining. — Chino Bond Issue.—Lumber in Mexico.— Consolidated Gold Fields Expansion.—Calumet & Hecla Merger.

The possibilities of Porcupine as a mining camp; the possibilities involved in the attitude of the public; the possibilities in the way of promotion enterprises, are absorbing the entire attention of the Eastern mining markets. Railway shares and the industrial issues traded in on the New York Stock Exchange have aroused no public interest for many months. It is not at all surprising, therefore, that a show of interest throughout the country should be immediately, almost instantly, followed by a flood of promotions. 'The Porcupines' have already achieved something of a market triumph in that all the activity is centred in these issues. The trading in these stocks in the open market has grown to such proportions that there is some talk of the formation of a new mining exchange to be organized under the Canadian laws, to handle

Map of Eastern Canada.

Porcupine stocks exclusively. It is not as yet known whether such a move can obtain the sanction of the New York Stock Exchange authorities or not. There is no question but what the Stock Exchange houses are about as hungry for business as are the outside curb brokers. The leader is Hollinger; a large interest in this company is said to have been taken by Bewick, Moreing & Co., with the result that London has been buying the stock, thus making an excellent market on this side, where it has been easily advanced to $10.50. The company has a capital of $3,000,000; 600,000 shares of a par value of $5. On the basis of the market for this week, the property would have a valuation of $6,000,000. The Dome property is organized as a close corporation; bids have been made in the open market of $80 for the stock, which would be giving that property a market value of something like $16,000,000. The day is counted wasted that does not see a new issue added to the list, and the activity of the

traders can only be likened to a bunch of ravening, half-starved dogs at feeding time. It has been many a weary day since the outsider has come into Wall Street, and the few who are venturing now are fallen upon with an enthusiasm that stops short of murder only. One of the well-known brokers of the Street was asked what he thought about the future of the market in Porcupine issues. His response was: "They will sell 'em the ice-fields 'Doc' Cook traveled over going to the pole if the people will keep on buying." The one absorbing problem at the moment is whether the present movement is the first lift of a great flood-tide or just a ripple that will pass as quickly as it came. The supporters of the camp are all pointing to the investment of English capital, by the Bewick-Moreing people, the Consolidated Gold Fields of South Africa, the MacArthur-Forrest company of Glasgow, and others, as being indicative of great possibilities.

Coppers are for the time neglected. The International Smelting & Refining Co. is extending its activities. The Raritan plant of the company is to handle the blister from the British Columbia Copper Co.; the Miami blister will also go to the Raritan plant for refining, after being sent from the Miami to smelter at the Greene-Cananea. Perhaps this forms as patent an illustration as any of the concentration already accomplished in the making, handling, and selling of copper. Ores from British Columbia and from Arizona alike pay tribute to the Standard Oil interests as represented by the International Smelting & Refining Co. In truth, this element is also the predominant reason for the lack of interest in the general stock market and is the main cause of the public interest manifested in a possible new goldfield. The individual very naturally prefers to get into a field where individuals can still play a part, and to avoid commitments in a field where the domination by large interests is as complete as it has come to be in railways and the larger industrials. In copper, the centralization of interests can only be likened to the movement that took place when the iron-ore and steel-mill interests were gathered into the present steel trust. The various steps are now being made without attracting much attention. Butte & Boston is soon to be wound up, and, like the Boston & Montana and the Trenton, will cease to have a separate corporate existence. There are some enormous vital economic problems to be worked out in the future as to centralization of control of great natural resources. More has been heard recently perhaps in regard to timber, lumber, and coal than in regard to copper, but there is no more striking example of the elimination of the individual and the concentration of ownership than the present situation in copper.

The final financing of the Chino Copper Co. has been arranged for by the issuance of $1,000,000 in promissory notes, maturing July 1 next, at which time there will be a $2,500,000 bond issue made which has already been underwritten by Boston interests. The note issue is made necessary by reason of the fact that the charter of the Chino Copper Co. forbids any increase in the capital stock or the incurring of any indebtedness in excess of $1,000,000 within a period of two years from the date of the organization of the company, which was June 9, 1909.

The disturbance in Mexico has ceased to frighten the Eastern investors. It is believed in the East now that within a few weeks tranquility will be fully restored. In the meantime, it may be said that the so-called revolution has not apparently interfered with the operations of the active mining companies.

The American Finance & Securities Co., which owns, through its subsidiary, the Guanajuato Mines & Reduction Co., the old Valenciana property at Guanajuato, Mexico, credited by history with being the greatest single precious-metal mine in the world, is about to embark in the lumber field. The company is now offering to the public a $4,000,000 bond issue, the proceeds to be used in the purchase of a tract of timber land on Vancouver Island.

Mr. John Hays Hammond is to become once more prominently identified with the Consolidated Gold Fields of South Africa, Ltd. This company has recently increased its capital by the creation and issuance of $6,250,000 of second preferred cumulative 6% stock. The proceeds of this stock issue are to be utilized mainly in the mining enterprises recently undertaken on this side of the water. Mr. Hammond is to head a staff of consulting engineers to act for the company and to have headquarters in New York.

The management of the Calumet & Hecla is considering the erection of a second plant for the treatment of old sand. The new plant is to be equipped with tube-mills, and it is thought a higher recovery can be effected than is obtained now by the first plant which is treating the tailing from the mill. The hearing on the restraining order preventing the merger of the Calumet & Hecla and the Osceola has been adjourned from Grand Rapids to Detroit, Michigan, and is now proceeding before the United States District Court.

LONDON

Hodgkinson Patents.—Soda Deposits in East African Protectorate.—Transvaal Mining.—Mysore Gold Mines.

Some sensational paragraphs have recently been published in the English and American papers relating to a new process for refining salt, invented by James Hodgkinson, of Bowman, Hodgkinson & Co. Announcements in the American daily papers of new discoveries are usually exaggerated, and it is advisable to state the facts of the case. In the present case Mr. Hodgkinson's invention relates to an improved method of refining brine, and it is reported in America that United States capitalists have paid a million pounds for the rights. There is not much profit in salt-refining, and Mr. Hodgkinson would be delighted to part with his invention for so large a sum, just as Lord Lansdowne would be glad to sell an old oil painting for £100,000 to any millionaire in America that wants it, or as the shareholders in the White Star Line were pleased to sell their shares through J. Pierpont Morgan for four times their real value, when they had the opportunity forcibly offered them. The Hodgkinson English patents have been provisionally acquired by the Salt Union, but they will not be bought until the value of the process has been proved.

In various parts of the world natural deposits of soluble salts are found. The deposits of potash salts at Stassfurt, Germany, are perhaps the most renowned, and those of borax in California are of hardly less importance. An unusually large deposit of natural soda has been found in the British East Africa Protectorate, at Lake Magadi, not far from the Uganda railway. A company has been formed in London for the purpose of working it, under the auspices of H. Samuel & Co. of 'Shell' oil fame, and Wernher, Beit & Co., and £1,250,000 in cash has been raised for the purpose of building a branch railway and the necessary plant for treating the soda. The deposit consists of trona or urao, sometimes called sesqui-carbonate of soda. This salt is composed of two molecules of bicarbonate, one of monocarbonate, and three of water. It has been found from time immemorial in Egypt and other parts of north Africa, and more recently in Hungary, India, and Western America. It has generally been formed by the evaporation of sodium carbonate solutions, and as it is taken away more is deposited. The deposit at Magadi is so extensive that there is every reason to believe in its commercial value. The method of treatment will be to heat it to a dull red, thus expelling water and forming soda ash. This treatment will not only produce a readily salable product, but it will expel all the water and part of the carbonic acid, and so reduce the bulk and weight of the material shipped. The heat required for this treatment will be supplied by oil fuel. Unlike many deposits of the kind, that found at Magadi is practically free from admixtures of other salts, such as sodium chloride and sulphate.

The gold mines in other parts of the Transvaal than

the Rand have given much trouble to English investors. A good example of this is the Lisbon-Berlyn Company which was originally formed in London in 1885 to acquire properties in the Pilgrim's Rest district. This company has been reconstructed no less than five times. The last time was in 1906, when the control passed to the Hamilton-Ehrlich group. E. T. McCarthy was then made consulting engineer, and a drastic reorganization of mining and milling methods was made. The old properties, Lisbon and Berlyn, were abandoned, and the work concentrated on the more recently acquired Frankfort property. The deposits are found in bedded form intercalated between dolomite and shale. There are two principal beds, the Theta and Bevitt's, the latter 250 ft. above the former. Their outcrops have been traced for a considerable distance, and the amount of ore must be immense. The ore is oxidized at the surface, and as the drifts go in, pyritic ore is found. So far the treatment of the oxidized ore only has been considered. The old plant was in a dilapidated condition, and it was decided to build an entirely new one on modern principles. The new plant was completed in November, and the old plant was kept running until the end of June. The new mill contains 20 stamps, amalgamating tables, tube-mills, cone-classifiers, sand vats, and Brown agitators, otherwise Pachuca vats. The capacity is 3000 tons per month, but so far it has not been possible to treat more than 1300 tons per month on account of lack of water. To make up for the deficiency of water-supply, a gas power-plant has been ordered and should be ready for use in May. The recovery in January was 86%, which is a great improvement over the results obtained in the old plant. In spite of the drawback of short power, profits have been made since the starting of the new plant amounting to £3948 during the four months, November to February, inclusive. Mr. Hunter, the manager, estimates that the ore blocked out on September 30 amounted to 19,615 tons, averaging 9.8 dwt. The amount of development work done during the year was 8115 ft., and 2.6 tons of payable ore was uncovered for each foot of work done. Prospecting has been renewed at the Lisbon and Berlyn properties, and a number of rich leaders have been found on the former. Probably the company will not work these, but they will be let on rent or royalty to tributers.

In a recent issue I gave a history of gold mining in India, and I recorded that some of the old mines were now in as productive and promising a condition as ever. John Taylor & Sons, the managers of the mines in the Kolar district of Mysore, do not publish anything but official news, and any Stock Exchange speculation that takes place is due entirely to outside influence. Just recently adverse rumors have been circulated about the premier mine of the district, the Mysore. Of course, a mine that has been a regular producer for 25 years and is down 4000 ft. may be supposed to have, by the law of averages, an expectation of life that does not warrant the present quotation of 10s. shares at £5 10s., although the year's dividend has been 115%, the reserves sufficient for 4 years, and the developments satisfactory at a greater number of points. It is well, under the circumstances, to quote the report for 1910, so as to show that adverse reports are mere inventions. During 1910 the largest yearly amount of ore was treated, and the largest yield produced since the commencement of operations, and though the deepest workings are 2800 ft. vertical from the surface or 4000 ft. on the incline, the ore reserves and the development results are as satisfactory as at any time in the history of the mine. These facts are naturally a cause of great gratification to such old believers in the Kolar district as Captain McTaggart and General Beresford, and, of course, to John Taylor & Sons. During 1910, 246,425 tons of ore was crushed in the stamps, and 201,056 oz. bullion recovered by amalgamation; in addition, 190,530 tons of tailing was cyanided and yielded 27,631 oz. The total production of gold was worth £895,467, which was £600 more than during 1909. The yield since 1884 has been £12,575,989. During 1910 the working cost was £355,489, royalty to the Mysore government £47,910, income tax £25,131, depreciation £8503, and expenditure on plant, etc., £73,524. The dividend absorbed £350,750, which was at the rate of 115%, and £40,000 was placed to the reserve fund. The actual amount of profit was apparently less than that for the years 1904 to 1907, but it must be remembered that nowadays all expenditure is charged against revenue instead of as in former times special expenditure being provided for by the issue of new shares. For some years the grade of the ore has been slightly diminishing, but improved methods of mining and extraction have more than counterbalanced the fall in contents. In fact, the costs per ton during 1910 were 4s. less than those for 1909. During the past year, 32,383 ft. of development work has been done, and the ore reserve has been increased by 87,803 tons, standing on December 31 at 1,100,453 tons. The report by the superintendent, Arthur Gifford, shows that the developments continue to be satisfactory. The equipment of the new vertical circular shaft, Edgar's, sunk for the purpose of facilitating operations in the northern part of the mine, has been completed for some time, and the surface plant is now being erected. It is proposed to sink another vertical shaft with circular cross-section at the southern end; the present shaft is not convenient for hauling, and the winding engine has come to the limit of its capacity. The new shaft will be 16 ft. diameter and is to be sunk to 2400 feet.

MEXICO

Transportation of Ores Interrupted. — Smelting Operations Curtailed. —Mines Short of Blasting Powder.—Electric Power in Jalisco.— Mining Operations in Hostotipaquillo. — The Mazapil Copper Mines.

Railroad communication with Chihuahua from the south, interrupted by Mexican rebels a few weeks ago, has been re-established, and if it can be maintained the Chihuahua smelter of the A. S. & R. Co., the Santa Eulalia mines, and other concerns will not be forced to shut down. The smelter was running short of fuel, and the mines of fuel and explosives. The Mexican Central line between Chihuahua and El Paso continues out of commission, and due to this interruption and to traffic interruptions on the Mexico Northwestern, the El Paso smelter, also an A. S. & R. Co. plant, has been forced to curtail operations. Rebel activity at the Naica camp in Chihuahua, and the traffic interruption south, have affected both the San Luis Potosi and Torreon smelters, by stopping shipments from the lead mines of the Compañia Minera de Naica. The latter has been unable to close its old contract with the San Luis Potosi plant, or to start deliveries under its new 300,000-ton contract with the Torreon plant. The company has been supplying an average of 4000 tons per month to the San Luis Potosi smelter, and has still to deliver about 2000 tons. When the rebels became active in Durango, some time ago, the Government extended its order against transportation of explosives to the railroad lines in that State, and as a result it was recently announced that the Velardeña smelter and mines of the American Smelters Securities Co. would be closed April 1. Later, however, it was stated that the Government had consented to allow shipments of dynamite, and the threatened shut-down probably will not take place. Mine operators of the Parral district of Chihuahua are in need of dynamite, and early shipments will be necessary to enable them to continue operations. The question of supplies has become serious in some of the Chihuahua mining camps, forcing companies to suspend work. Recent rebel activity along the Nacozari railroad, in Sonora, has caused apprehension among the mining companies dependent on that line for supplies and the transportation of their products. These include the Moctezuma Copper Co., and the Lucky Tiger Mining Co. The occupation of Cananea has been threatened by the rebels, but so far no attack has been made. The cutting of railroad communication with Cananea would force the

Cananea Consolidated to cease operating, through inability to secure fuel oil. The Mexican Congress has suspended certain constitutional guarantees for six months, making all classes of rebel depredations subject to summary punishment. José Ives Limantour, the finance minister, has returned to Mexico from Europe, and interesting developments are expected. President Diaz has announced that big tracts of land will be purchased and divided by the Government, and sold on easy payments. The mobilization of American troops near the frontier has caused much speculation and some uneasiness.

The transmission of power over the new line of the Chapala Hydro-Electric Co., of Guadalajara, has been commenced. The Amparo Mining Co., of the Etzatlan district, and the El Favor Mining Co., of the Hostotipaquillo district, of Jalisco, are receiving current. The Amparo company has a credit on its power contract of ₱63,000, the contract specifying a penalty of ₱100 per day for failure to deliver power from July 1, 1909. Under a similar provision, El Favor will be credited with ₱50 per day from October 1, 1909. In the Hostotipaquillo district a pole-line has been built from the El Favor camp, where the tower-line ends, to the reduction plant of the Virginia & Mexico Mine & Smelter Co., of Richmond, Virginia, and the company's mines were shut down last year. The plant will be operated under a lease by the Espada Mines Co., and an aerial tramway will be built to deliver ore. Pole-lines will be built to the Casados, Amajac, Mololoa, Mirador, and other properties in the district. Ore shipments, resulting from development work in the Casados mine of the Consolidated Mining Co., run from ₱15,000 to ₱20,000 per month. Work is in progress on a 150-ton reduction plant. The Amajac Mines Co. is completing the remodeling of the old Amajac reduction works, and will have a 75-ton sucton plant in operation within a few months. This company has developed 50,000 tons of ore in the Trinidad property, and will build an aerial tramway to give the mine connection with the mill. Work has started on a 15-stamp concentrating and cyaniding plant for the Mirador Mining Co. The power contract of the Amparo company calls for 700 hp. at ₱100 per horse-power-year, and a big saving in operating costs is certain. In 1910 Amparo earned profits of ₱637,000, and paid 12% on its capital of $2,000,000.

To avoid, it is said, possible forfeiture of the concession, the Franco-Español Bank syndicate, financing the projected railroad across the northern part of the State of Zacatecas, has purchased all rights of the Madero interests. Gustavo Madero, a brother of Francisco I. Madero, interested the French in the project, and obtained from the Zacatecas government a guarantee of 5% on the money invested for 20 years. It was recently announced that work would be commenced April 1, but the present trouble in Mexico may delay construction. The line will extend from Camacho, on the Mexican Central, to Mazapil, with a branch to the Bonanza mining camp. According to the plans, the Bonanza line will eventually be extended to Gomez Farias, on the National. The line will be of much importance to the mining industry in northern Zacatecas. It is stated that the same French interests may take over Coahuila coal properties owned by the Maderos. The Mazapil Copper Co., the most important of the mining concerns of Zacatecas, in 1910 earned about 20% on its capital of £300,000. The company is continuing its policy of devoting a large part of its earnings to betterments and extensions. The Santa Rosa Mining Co., recently launched in London by the Exploration Co., Ltd., to operate the Santa Rosa properties in the Mazapil section of Zacatecas, is proceeding with plans for a reduction plant at the mines. Under an option, the Exploration company spent a large sum in development work, and a few months ago took over the mines. The Clement-Williamson interests were the former owners. In February the Cananea Consolidated Copper Co. produced 3,906,000 lb. of copper, 98,424 oz. of silver, and 468 oz. of gold. The copper production was 300,000 lb. greater than in January, and the heaviest of any month since last July.

JOPLIN, MISSOURI

American Zinc, Lead & Smelting Co. Secures Rich Leases. — Recovery of Slime Key to Profitable Mining. — Open Pit Mining at Galena, Kansas. — Zinc and Lead Notes.

The biggest deal in the history of the Missouri-Kansas-Oklahoma zinc and lead district is pending, the American Zinc, Lead & Smelting Co. having taken over 640 acres of the Charles B. Guinn land, in the sheet-ground district northeast of Webb City. The lease carries with it an option to buy the fee within a year. The expansion of the American company's holdings is considered convincing evidence that this colossal company, the largest operating in this district, has found it cheaper to mine its own ores than to purchase them in the open market, despite reports that operations in the thin sheet-ground districts, where the ore-content will not run more than 4% of the material milled, have been at a loss. The American company, working in ground that is recognized as the thinnest regularly producing area in the district, has made the largest ore returns of any of the companies. The Guinn leases carry virtually the same grade of thin sheet-ore. Big producing companies now operating on the Guinn land are the Hea Lead & Zinc Co., the Ground Floor, the Ice Plant, the Osceola, the Electrical, the Home Run, the Holdout, and others. All these companies operate large plants, ranging in capacity from 200 to 500 tons per shift. Several of the companies work a number of mills. The total production from this property has been well up toward the top of the Webb City lands. The production coupled with that from the present big mines of the American company will bring the aggregate to approximately 1,300,000 lb. of zincblende and 800,000 lb. of lead ore weekly, and this is a very conservative figure, especially the blende, which, under favorable circumstances, could easily aggregate 2,000,000 pounds weekly. H. S. Kimball, president of the American company, and J. H. Polhemus, general manager of the mines, have gone to Wisconsin with the view to considering the erection in this district of an electrostatic separating-plant similar to the ones now working in the Wisconsin zincfield and in the Western zinc district.

At the mill of the Oronogo Circle Mining Co., operating on the Granby Zinc & Lead Co.'s property at Oronogo, especial attention is given to the recovery of slime, and a new process, by which even greater recovery may be made, is receiving attention. After the tailing has been dewatered over a revolving screen, it passes onto a second revolving screen and then to the third. The first revolving screen has been in use several months and has proved successful. The two additional screens have just been erected, and the percentage of slime saving is being watched with interest. The screens are of 1½-mm. mesh, are 4 ft. in diameter and are 3 ft. long. At intervals of 10 in., wooden sections or paddles are inserted, these are 6 in. wide and run the length of the screen. They may be removed and new ones slipped in place promptly. These dividing partitions prevent the tailing from slipping when it is precipitated on the surface of the slowly revolving screen. Troughs, passing through the screens, receive the slime-laden water that passes through. At the first trough, the one passing through the revolving screen installed a number of months ago, the saving of the slime is about 70%; through the second revolving screen about 22% of the slime passes, and through the third screen 8% passes, thus making the total recovery 100%, according to the estimates of the company. This slime-laden water passes into settling-tanks. From the first tank it passes into a second, then into a third, from which it is permitted to flow into the sludge-pond. After passing through the third tank it is clear, yet despite this fact, a small percentage of slime escapes, and an occasional cleaning of the sludge-pond becomes necessary. The plant is equipped with ten sludge-tables.

Zinc ore, which outcrops in lodes, and which comes to within 5 ft. of the surface over the greater portion of the lease, is being mined from a 5-acre tract of the Wind-

sor land at Galena, Kan., by the Galena-Open Cut Mining Co., a new concern composed of Niagara Falls capitalists, which has just been incorporated. The tract has been mined in the old-style manner of driving for more than 30 years; ore has been worked down to the 100-ft. level in the early-day mines. The new company has opened a pit, 100 ft. across and 50 ft. deep, and has erected a concentrating plant with a capacity of 200 tons per shift. Everything from the surface down is shot in and milled. An inclined tramway leads down to the level of operations. When it becomes necessary to go deeper the company intends to take up a stope 30 ft. high.

Tailing-mills are handling the product of the old mines of the Alba district, which was considered the phenomenally rich quarter of the district a number of years ago. Few of the mines are now operating, but the reworking of the tailing is netting a profit to the operators. The ore of the Sitting Bull mine, on the Brinkerhoff land, at Toms Station, north of Joplin, is showing the almost unbelievable record of running 60% zincblende, mill recovery, and the tailing is not well cleaned at that. The ore is found at 187 ft., and occurs in a veritable mud-hole, requiring the closest kind of timbering. It is the richest recovery ever made in the district from a mine of any size, but, due to the pockety formation of the ground, no assurance is felt by the operators that it will long continue so rich. Prior to mining this land, Jess Short, the superintendent, sunk a drill-hole in the centre of a hog-wallow. Other holes were sunk near-by, and all showed more or less pay-ore.

GLOBE, ARIZONA

Drill Work at Arizona Commercial.—Opening Summit Vein at 600 Ft. —The Miami Mill. — Inspiration Development. — The Live Oak, Warrior, Superior, and Boston.

Recent drill prospecting at the mine of the Arizona Commercial Co. has disclosed high-grade ore below 1000-ft. depth. This is in line with the predictions of those familiar with the property, based upon the evidence of extensive leaching in the upper levels of the mine, presaging a zone of secondary enrichment beneath. The diamond-drill passed through 14 ft. of 16% copper glance at a depth of 1000 ft., and cut into a body of 11% sulphide ore at about 1200-ft. depth. The drill did not penetrate the latter, being withdrawn after boring into the sulphide 10 ft. The contract of the drilling company had expired, and as the Arizona Commercial management had decided to sink immediately and explore that section with drifts and cross-cuts it was decided not to resume drilling until the 1000-ft. level is opened sufficiently to install the air-drills there. At the summit mine cross-cutting has been commenced at the 600-ft. level, to open the Pasquale vein 500 ft. west. If the size of the vein and the grade of the ore at this depth are similar to those above, where the vein contained chalcopyrite sampling 30% copper, and widened from 10 in. at the 200 to 4 ft. at the 400-ft. level, the Summit will become one of the best copper properties in the Southwest. The 30% ore occurs in a streak within an 8-ft. vein carrying 16% copper at 400-ft. depth. A 200-ton concentrating mill will be built at the Summit as soon as the equipment can be placed on the ground. The old dumps of the mine consist of concentrating ore of high grade, and abundance of ore of lower grade has been exposed in the mine. A hoisting-engine and air-compressor have been moved to the New Keystone group from the Miami, and operations there will be resumed soon. Work at the Copper Reef continues, and considerable ore has been found at the face of the California adit, now about 750 ft. from the portal. The value of the ore is not definitely known, but it is probably of commercial grade. The stockholders will meet at Globe, April 23, when doubtless it will be decided to push development work at an increased rate.

The Miami Copper Co.'s concentrator is in operation, three units handling ore the last day of March. Everything in and about the mill and mine has been ready for operation since March 14, but the non-arrival of 14-in. pipe for the water-line from the pumping plant at Burch to the mill delayed full operation. Units 2, 3, and 4 are complete, but units 1, 5, and 6 will not be in operation for some time because portions of the equipment have not yet arrived. Considerable water is being supplied by a temporary 8-in. pipe-line, and while the three units now running are handling about 900 tons of ore daily, they are expected to treat 500 tons each per day when in perfect running order. At the mine the caving method is well started and working with precision. Electric locomotives are in use underground, hauling the ore to the ore-pocket at the south side of shaft No. 4. The hoisting engines, cages, and skips are in perfect order. There is now a considerable tonnage of concentrate in the cement tanks on the western side of Miami butte. The mill is on the top and eastern slope of the butte; a tunnel leads through the hill, and the concentrate is passed from the mill through it by means of a trough, and is emptied into six cement tanks at the farther end of the tunnel, where it it dried by vacuum pumps, set beneath a false canvas bottom in the tanks. The Burch rolls are apparently a success. They differ from other ore-pulverizing machinery in that one of the rolls is moved slowly back and forth in the direction of its axis, thus preventing the grooving that limits the life of stationary rolls. The expected selection of the Inspiration's concentrator-site has not yet been made. Company surveyors have been at work near Wheatfields, ten miles northeast of the mine, but nothing definite has been done toward providing for a site there. The placing of a mill at that point would involve building a branch of the Arizona Eastern railroad along the survey of its proposed Globe-Durango line. Development undoubtedly would yield a water-supply three miles west of the mine, as drilling by the Cactus company tapped what is apparently a large underground flow in that region. This company's Colorado shaft is finished, and a pocket has been cut on its south side. Station-cutting is almost completed and a drift will be started early in April to connect with the 500-ft. level of the Joe Bush shaft. This drift, a portion of the main haulage-level, will contain a 36-in. gauge track when finished. Churn-drill holes 1001 and 1007 are still in ore. Hole 1008 passed through the ore at a depth of 450 ft. No. 1009 has just been started. Between 10 and 15% of the Inspiration ore is being found in granite. Various tables are being tested at the Inspiration's 75-ton test mill.

Two shafts are being sunk on the Live Oak group. The old shaft is being sunk from its former 308-ft. station. It will be sunk 70 ft., to a point about 180 ft. below the adit that formerly exposed the sulphide orebody. At the bottom of the shaft a new station will be established and the work of blocking out the orebody will be begun. The new shaft, work on which began April 1, is situated on the western part of the company's ground, about 1600 ft. west of the old shaft. The new one is to be sunk to a depth of 1200 ft. The ground it will open has been proved by drill-hole 38. The drilling at the Live Oak continues to give favorable results. Ore 200 ft. thick was penetrated in hole 50; 47 is still in ore at 950 ft., and the other holes are showing satisfactory progress. The Warrior Development Co.'s underground exploration is progressing as usual, and churn-drilling will be begun soon. The main west drift is still in ore at about 140 ft. east of the Winnie shaft and less than 500 ft. from the Warrior's west side lines. From 100 to 125 tons of 9½% ore is being shipped daily to the El Paso smelter. The Superior & Boston company recently completed the raise on the Great Eastern vein from the 800 to the 600-ft. level, which marks the last of the extensive dead work that has been necessary in this mine during recent months. It provides ventilation and establishes a channel for extraction of the ore developed on the 600-ft. level, and along the raise. A drift is being driven in a southwesterly direction from the 1000-ft. level to cut the Great Eastern. When the vein is reached the drift will be extended along its strike, and a cross-cut will be driven north to cut the Old Dominion fault.

General Mining News

ALASKA

KENAI PENINSULA

The placer-mining claims recently staked on the Kenai river cover an area of nearly a mile in width on each side of the stream, and extend along its course from Skilak lake as far as the town of Kenai. This river flows through a broad valley in which are extensive deposits of gravel, believed to be rich enough in placer gold to make this a profitable dredging field. It seems certain that the gravel will be thoroughly tested next summer.

PRINCE WILLIAM SOUND

The Cliff mine, near Valdez, has a stamp-mill which was operated profitably last year, and it is to be started again this month with increased capacity. The Cliff is a gold mine, and some dividends have been paid out of its proceeds. It is owned mostly by Valdez people.

ARIZONA

COCHISE COUNTY

The Bisbee-Sonora Development Co. has maintained a small force of miners on development work during the last four years, and it now has a sufficient tonnage of ore exposed to enable it to ship ore to the smelter regularly. The property is situated in the Chiricahua mountains, 18 miles from Rodeo station. The orebodies are opened by

Copper Queen Power Plant.

adits to a depth of 400 ft. The ore to be shipped samples $40 to $50 per ton.

The Copper Queen Co., which operates the Copper Queen mines at Bisbee, and the big smelting plant at Douglas, smelted 589,900 tons of ore in 1910, recovering therefrom 122 lb. of copper per ton, an aggregate for the year of 71,928,357 lb., which was produced at the cost of 6.5c. per pound. The company marketed its product at an average price of 12.826c. per pound. The Lowell shaft of this company, at Bisbee, has reached a depth of 1600 ft., at the bottom of which a station has been cut, and driving has been commenced at the 1500 and 1600-ft. stations in the direction of the Sacramento. A new shaft, to be known as the Dallas, has been begun, on which three shifts per day will be employed, with the expectation of sinking at the rate of 100 ft. per month. A pipe-line, connecting with an air-compressor at another plant, has been laid to supply power for the drills. This sinking is expected to extend to a depth of 900 ft. in limestone before cutting the orebody.

The Hartford-Arizona mine, in charge of Henry Hamburg, is to have an aerial tramway, two miles in length, to carry the ore from the mine through a box canyon to the shipping bins. A 125-ton steam boiler was put in lately at the mine. The property is in the Huachuca mountains. High-grade gold and silver ore is being shipped regularly from the Herschel mine, at Tombstone, the mining operations being under direction of Douglas Gray.

GREENLEE COUNTY

The New York-Arizona Gold & Copper Co., which has developed bodies of gold and silver ore in the Clifton-Morenci district, is making tests to determine the method of extraction best suited to the ore. It is anticipated that a cyanide plant will be erected.

PIMA COUNTY

The Arizona Con. Smelting & Mining Co., organized in New York, is said to be considering bids for the construction of a smelting plant within three miles of Tucson. It is stated that the smelter and accessories are to cost $350,000. H. A. Thompson, the manager, is entering into contracts with mine operators for securing their ores.

The Twin Buttes Mining Co., which has thoroughly developed its copper mines at Twin Buttes, situated 20 miles south of Tucson, and which has been shipping about 2000 tons of ore per month to the El Paso smelter, is considering the recommendation of Michael Earle, president of the company, to discontinue its shipments, and begin the construction of a smelter of 350 tons capacity at the property. It is said the orebodies have been opened in 20 different places, and that the ore samples 6 to 10% copper. The superintendent is J. E. Higgins, formerly of Butte, Montana. The company has a narrow-gauge railroad extending from Tucson to the mines.

YAVAPAI COUNTY

The Eleanor Placer M. Co., with Joseph Mackin as manager, has its gold dredge in operation on French gulch, with plenty of water for floating the boat. W. J. Deam has taken the contract to drive a 1000-ft. adit on the grounds of the Copper Queen Co., on the Agua Fria river, five miles east of Mayer.

CALIFORNIA

BUTTE COUNTY

Natoma dredge No. 8, which has been operating about two months at Folsom, has proved so satisfactory that the Natoma Consolidated Dredging Co. is building what is to be Feather River Dredge No. 3, of the same capacity and pattern as the former; but No. 3 is being built on the company's ground at Thermalito. This dredge is 150 ft. long, 60 ft. wide, and has a chain of 15-cu. ft. buckets, capable of digging to a depth of 55 feet.

The Wyandotte quartz mine, belonging to John McBain of San Francisco, has been leased to S. Foden, also of that city, who is to operate it this season. It is said to be a paying mine, and the lessee has provided an air-compressor and power-drills, and has employed 10 miners.

ELDORADO COUNTY

The Hydro-Electric M. Co., composed of Colorado mining men, has acquired the French Hill claims, situated three miles north of Greenwood. The property covers a system of veins and reefs on the Mother Lode. Work on a small scale has been conducted for many years, the ore taken out having been treated in a 10-stamp mill that was built in early years of mining.

KERN COUNTY

The Mascot mining claims, four miles south of Randsburg, are being developed with good results. Five tons of gold ore taken from the vein recently opened is said to be worth $150 per ton. The general average of ore in a shoot 5 ft. wide is reported at $35 per ton. The claims belong to Powell and Humphreys. C. G. Illingworth and associates are mining high-grade ore on the 300-ft. level of the Pearl Wedge claims, in the Stringer district. They recently milled 15 tons at the Osdick plant. J. Cronan and Fred Williams, having a lease on the William R. mine,

in Springer district, opened a 2-ft. vein of ore assaying $40 to $50 per ton. This is a recent discovery, and is considered important. The claims belong to Houser brothers, F. Williams, and P. Byrne.

NEVADA COUNTY

The Coan mine, owned by a Pittsburg company, and in charge of D. McGonigal, has been equipped with a 10-stamp mill, and a new hoist. Five of the 10 stamps are in operation on ore being taken from the old workings. In the meantime, an incline shaft is being driven, by which the mine is to be more thoroughly developed. The Holbrook mine, at Grass Valley, has been leased for three years to H. Reber, O. A. Edholm, E. C. Webster, John Bolander, D. D. Enyeart, and T. K. Richardson, who contemplate sinking a new shaft for the purpose of tapping the gravel channel, which they believe is an extension of the Blue Lead channel. It is estimated that the bedrock will be reached at a depth of 125 ft. Hoisting and pumping equipment has been purchased.

PLACER COUNTY

The Annie Laurie and Red Bird mines, situated near Colfax, have been examined recently in the interest of San Francisco men who have under consideration the purchase of those properties. Both are gold-quartz mines.

RIVERSIDE COUNTY

The Calzona Mines Co. and the Steece Copper Co. are operating in Riverside mountains, situated near the Colorado river, and not far from the Parker branch of the Santa Fé railroad. The Steece company has a 380-ft. shaft, and is still sinking. The Calzona has a shaft, also, where a gasoline hoist was installed some time ago. The ore found in these properties consists of copper-iron sulphide, accompanied by some gold.

SHASTA COUNTY

The copper output of the First National Copper Co., operating the smelter at Coram, was 260,000 lb. less for February than was the January production. The January output consisted of 932,000 lb. copper, 41,232 oz. silver, 822 oz. gold; the February product was 676,705 lb. copper, 28,373 oz. silver, 526 oz. gold.

SIERRA COUNTY

The Four Hills mine, situated in the region of deep snow, half way between Sierra City and Johnstown, is attracting attention by reason of the recent opening of a shoot of ore in that mine, samples of which are said to have assayed $100 per ton. This mine is on the same mineralized zone as that on which the Sierra Buttes, Plumas-Eureka, and Jamison mines are located. The Four Hills belongs to Hood & Breesi, for whom J. B. Lassiatt is acting as superintendent. Mr. Breesi is a New Yorker, and Mr. Hood is an Englishman. They put in store a stock of provisions last fall, and have kept a force of miners at work at the mine all winter.

SISKIYOU COUNTY

The Hamburg Dredging Co. is reported ready to start work with its suction dredge, by which the fine gold is to be taken up with the sand on the bed of the stream. Its operation is near Yreka. The River Bend M. Co. is to operate this season between Walker and Oak Bar with its steam-shovel dredge. The Garvey Bar Dredging Co., having leased ground from the La Sheil M. Co., is to work this season with a clamshell dredge, which is being built. Several mines are in operation in the vicinity of Hawkinsville, including the Lemos, Phillips, Borba, and St. George, which are placer properties. There is plenty of unworked ground in the camp, and the prospects for the season's clean-up are good.

TRINITY COUNTY

(Special Correspondence.)—Persons reported to be representing the Guggenheims are understood to have taken options on the La Grange, Union Hill, Hupp, Spanish Flat, Woodbury, Field, and other hydraulic and placer-mining properties, together with W. W. Young's water rights on East Weaver creek. The options were secured by W. A. Boland of the Union Hill M. Co., and extend to October of this year. It is said that the deal will involve the investment of $15,000,000 to $25,000,000. It is understood that the holders of the options plan the construction of a series of reservoirs that will assure sufficient water to operate the great hydraulic mines continuously. The La Grange ranks as the largest hydraulic mine in California, while the Union Hill and Hupp are also noted properties. The flourishing condition of hydraulic mining in this county is due to the fact that the rivers are unnavigable and drain directly into the ocean; thus the anti-hydraulic regulations do not apply to the operation of Trinity placer properties. The success attending the operation of the Headlight mine at Carrville has attracted much attention to the district. As a result owners of near-by mines are arranging for vigorous work with the beginning of the dry season. It is reported that several men identified with the Butte Creek Con. Dredging Co., of Los Angeles, are about to commence the exploration of dredging lands near Lewiston. Representatives examined the holdings last year.

Weaverville, March 31.

TUOLUMNE COUNTY

(Special Correspondence.)—The Carlotta mine, near Tuolumne, recently bonded to John Oleson, of San Francisco, has been unwatered to a depth of 150 ft., and several tons of ore is now being taken out for a mill test. Development work has been resumed at the Carlin mine, west of Jamestown, under the direction of John Witney. For a time work will be confined to sinking. Preparations are being made for the resumption of development operations at the Copper King and Iron Mountain claims, situated southwest of Jamestown and owned by D. L. Mann. C. Allen has been appointed superintendent of the Tarantula mine, vice T. J. Russell, resigned. It is understood that the management will conduct development work on a very extensive scale. The Hazel Dell mine, above Columbia, has been bonded to Peter Bahten, and operations will shortly be commenced. The Black Oak mill is running steadily and the general outlook is decidedly good. R. A. Nicholls and associates, who are operating the Draper mine under lease, have begun milling ore. It is said rich returns are certain from the present mill-run. Work will shortly be resumed at the Hamburg mine, near Jamestown, in which S. W. Ludwig and several Eastern men are interested. Five stamps will be added to the Soulsby mill. The plant will then consist of four 5-stamp batteries. The prospecting-drill formerly used by the Phoenix Lake Mining Co. is being moved to a point on the Stanislaus river near Melones, where tests will be made to determine the value of gravel deposits. If results are satisfactory, a dredge will be built there. The 5-stamp mill at the O'Donnell mine, south of Jamestown, has been started on good ore. A hoisting plant is being installed at the Badger mine, situated south of the Rawhide. The property, which is owned by A. L. Ellis, of Gilroy, will be unwatered, so that it can be thoroughly examined by intending purchasers. The Mandich pocket mine, near the O'Hara, at Brown's Flat, which yielded liberally in years past, is to be re-opened and worked by Dusan Mandich, a brother of the former operators.

Tuolumne, April 2.

COLORADO

BOULDER COUNTY

John R. Wolff and associates are building a crushing-mill and cyanide plant in the vicinity of Sugar Loaf mountain for the treatment of ores of that district. The Colorado Metals & Chemical Co. has acquired the Bailey mill, at Eldora, which is being remodeled and equipped for the cyanide process. This company will operate the mill on ore from its own property near Eldora. The Metal Mining Association has plans for the construction of a cyanide plant for custom ores.

CHAFFEE COUNTY

It is reported that a milling plant will be erected on Lake

creek, close to Twin Lakes, for the concentration and cyanidation of custom ores of the Mt. Elbert region. It is stated that both local and Eastern men are interested in the project.

CLEAR CREEK COUNTY

(Special Correspondence.)—Poles are on the ground and wires will soon be strung for the conveying of electric power from the Sternberger plant up Fall river to the portal of the Lucania adit on Bellevue mountain. The contract for driving this adit 1500 ft. will be awarded during the next few days. An average of two carloads of smelting ore is being shipped each week from the Money Muck mine. The average value of the product is $30 per ton. A shipment of 300 tons of smelting ore from the Peters mine made a short time ago brought a settlement of $28 per ton. Gus Carlson is manager. Work on the King Bee mine will be started through the surface levels, supplementary to operations being carried on through the Newhouse adit. Shipments from the lower workings bring returns averaging close to $100 per ton in gold and silver.

Idaho Springs, March 30.

GILPIN COUNTY

The Frontenac Con. Mines, Ltd., operator of the Frontenac and Addudel mines near Central City, and the new concentrator at Black Hawk, is mining and milling 200 tons of ore daily, producing 70 to 80 tons per day of concentrate. These properties are under direction of Henry P. Lowe, as manager, and Sydney Tyler as engineer.

LAKE COUNTY (LEADVILLE)

The mines on Fryer hill which are being operated are Chrysolite, Seneca, Hayden, Virginius, Muidoon, Climax, Dunkin, Silver, Pittsburg, Robert E. Lee, Matchless, and Progressive, making that part of the district a busy place. The active properties on Breece hill are the Ballard, Penn, Galesburg, Highland Mary, St. Louis, Black Prince, Garbutt, and the Ibex with its many sets of lessees. The mines on California and Iowa gulches are likewise active, as are those on Carbonate hill and Big Evans gulch.

SUMMIT COUNTY

The dredging season has opened at Breckenridge, and all the dredges have begun operations. The Bucyrus dredge of the Colorado Gold Dredging Co. is at work on Swan river, where it handled 1,300,000 cu. yd. of material in 1910. The French Gulch Gold Dredging Co. has its Reiling dredge in operation on French gulch. This dredge has been overhauled, and provided with new buckets with manganese steel lips, and is expected to handle 600,000 cu. yd. of gravel this season. The Reliance dredge is also in operation on French gulch.

TELLER COUNTY (CRIPPLE CREEK)

The mines of the El Paso Con. Gold M. Co., situated on Beacon hill, are opened by four vertical shafts. The main shaft has a depth of 1000 ft., and connected with it there are seven working levels, whereby the El Paso, Tillery, and C. K. & N. ore-shoots have been developed. A drill-hole was sunk 332 ft. vertically from the bottom of the main shaft to the Roosevelt drainage tunnel, which served to relieve all the workings on and above the 1000-ft. level of water, rendering the 3000-gal. pump at the seventh, and the 1800-gal. pump at the sixth stations no longer of use there. The Roosevelt tunnel penetrates El Paso territory a distance of 1880 ft., and the Tunnel company drove a cross-cut, at its own expense, from its tunnel to the C. K. & N. water-channel, a distance of 540 ft., by which 4000 gal. of water per minute was added to the flow of the Roosevelt tunnel, the total volume now being over 11,000 gal. per minute. This work will result eventually in draining the company's system of ore-shoots to a depth of nearly 1300 ft. The development work performed between January 1, 1910, and March 1, 1911, as given in the company's report, amounted to 8262 ft., the greater portion of which was done by lessees, of which there have been 20 to 25 sets. All leases now in force are of blocks of ground on and above the fourth level; all below that level is to be worked on company account. During the last year the principal tonnage of ore mined on company account was taken from the fifth, sixth, and seventh levels of the C. K. & N. vein. It is stated that considerable ore is already broken on the seventh or 1000-ft. level. The Tillery and C. K. & N. veins have been connected by a cross-cut on the fifth level, a good shoot of ore having been opened in the latter. Other shafts, on the north end

The El Paso Mine.

of the property, consist of the Chance, Ajax, and Nicholls, the last named being over 700 ft. deep, and from it the Ajax ore-shoot has been developed. The superintendent of the mine is John H. Nicholls, T. R. Countryman being the company's engineer.

IDAHO

SHOSHONE COUNTY

The Bunker Hill & Sullivan Mining & Concentrating Co., on April 4, paid dividend No. 163, amounting to $81,750, making total dividends to date of $12,620,100.

ILLINOIS

HARDIN COUNTY

(Special Correspondence.)—The operators of the Rosiclare Lead & Fluor Spar Mines, situated on the Ohio river, have about completed a mill of 500 tons daily capacity. There are three steel buildings, one each for the power-plant, separating and sorting equipment, and concentrating machinery. The equipment was made from the most modern patterns which have been devised. An electric haulage system has been established in the mine to facilitate the movement of ore to the mill.

Rosiclare, March 27.

NEVADA

(Special Correspondence.)—Mine Rescue Car No. 4, in charge of Sumner S. Smith, which was called to Nevada from Wyoming by the recent disaster at the Belmont mine, at Tonopah, made a stop of a few days at Reno on its return trip in order to give the students at the Mackay School of Mines an opportunity to learn of the equipment and work of the car. A lecture was first given by Mr. Smith at the University on the work of the mine rescue cars. This lecture was illustrated by numerous views of the work done. Each class visited the car, and each of the students was given practice with the Draeger oxygen helmets. While wearing the helmet each student was given some manual labor to perform in order to better acquaint him with its use. The error on the part of most of the students at first was that there was a tendency to work faster than their air-supply, but they soon got used to this, and in the cases where the student did not overexert himself he experienced no difficulty in working with the apparatus on. After using the helmets, work was given in providing first aid to the injured. A short course in first-aid practice is given at the University to each mining class of the School of Mines before graduation.

Reno, March 27.

ELKO COUNTY

(Special Correspondence.)—The second season in Jarbidge district opens favorably, with conditions promising

for the future. The developments of the past year have resulted in opening many large bodies of ore, which, with further development, will require several reduction plants, some of which may be built this season. The new map of the Jarbidge district, revised to date, prepared by W. W. Fisk, covers an area seven miles north and south by nearly four miles east and west, throughout which properties of proved value exist. The greater part of this area, however, has received as yet but little systematic prospecting or development. Numerous veins have been discovered upon which no development work has been done to find the ore-shoots. But the experience of the last year has given the prospector a better knowledge of the formation.

The Jarbidge Nevada Co., which has a group of claims lying west of Bear creek, is doing work to develop a large quartz vein. Ore of low value has been found on the surface, and an occasional panning can be obtained. An adit is being driven and a shaft is being sunk. On this outcrop fluorine stain is observed, which in Cripple Creek is taken as an indication of rich ore. This cropping is believed to be the extension of one of the Pavlak veins. The Ham And-Jarbidge Co., owner of the Valley View, is preparing for extensive development, expecting good results, as the Rainbow-Amazon Co. drove a 150-ft. adit just south of the Valley View, and opened an orebody 20 ft. wide, the samples of ore taken out assaying $8 to $16 per ton. The Ham And-Jarbidge Co. is developing leased ground lying south of the Pavlak tunnel, having driven 175 ft. on the Ham And vein, in which there is 5 ft. of milling ore, and 20 in. of high-grade ore. The orebody found in the Rainbow-Amazon was opened by an adit 150 ft. below the surface, and this is considered one of the largest bodies of ore of milling grade thus far found in the district. The lessees on the block of ground north of the Pavlak tunnel have opened two veins, in one of which is ore 6 in. to 3 ft. wide, most of it high grade. A shipment of ore made from this lease last fall netted $1360. The Pavlak tunnel which cross-cuts the vein system at 200 to 350 ft. in depth, has intersected some of the veins at a place where they are contracted by a quartzite dike. Four veins were cut before reaching the dike. The 150-ton cyanide plant of the Pavlak company will be completed in a few weeks, and it is probable that it will be operated partly on custom ore for some time, while the Pavlak company is developing.

Jarbidge, March 30.

NYE COUNTY

The West End Con. Mining Co., for which S. H. Brady is manager, is reported to have purchased the 20-stamp mill of the Midway M. Co., at Tonopah, and that it purposes remodeling and partly re-equipping the plant to make it more adaptable to the recognized Tonopah mill practice. It is announced, also, by the Tonopah *Miner*, that the MacNamara M. Co. has decided to erect a milling plant of a capacity of 2000 tons per month, to be equipped with stamps, tube-mill, agitating-tanks, and slime-filters. The MacNamara adjoins the West End mine, and is under the management of Herbert Haas. There are two veins on the property, in both of which the orebodies are well developed. There are now four mills operating on Tonopah ores, and with the building of two more Tonopah will become still more conspicuous as a camp of interesting and successful mill-work.

For the week ended April 1, the output of the mines at Tonopah amounted to 8493 tons of ore, distributed as follows: Tonopah M. Co., 3500 tons; Belmont, 2509; Montana-Tonopah, 1054; Tonopah Extension, 980; West End, 450 tons. The estimated realizable value of this ore is $212,325.

(Special Correspondence.)—The marble claims, 7 miles southeast of Gold Centre, held for several years by Sam Callicotte and son, have recently passed to the control of the American Marble Co. of Chicago. The locality is about 3 miles east of Chloride siding of the L. V. & T. railroad. A carload of machinery is on the ground and is being put in position, together with camp buildings and other structures. The machinery now on hand is principally for testing the marble deposits and consists of Ingersoll-Sergeant core-drills, and an air-compressor run by gasoline power. The marble is of the pure white kind, as well as the variegated, and takes a good polish. Some of the strata are thick-bedded, and it is believed that when the surface outcrops of the different measures are removed, the material will be of excellent character, and can be quarried in large blocks. The wagon-haul is down hill to the railway. Mr. Graves of Chicago is directing operations for the company.

Rhyolite, April 1.

WHITE PINE COUNTY

Mine Rescue Car No. 4, in charge of Sumner S. Smith, was at Copper Flat, Giroux, Ely, and McGill a few days last week.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Maud M. Co. began recently to put the Maud S. shaft equipment in such condition as will make it possible to unwater the mine and begin mining operations. This is an old property and is considered one of merit. The clean-up at the Socorro mines for the first half of March consisted of 17,000 oz. of gold and silver. About 150 tons of ore per day is being milled. The Ernestine M. Co. cleaned up 6920 oz. of gold and silver during the first ten days in March. For one week 43 sacks of concentrate was produced from 660 tons of ore. The week's work at the Deadwood mine consisted of milling 240 tons of ore, and producing 15 sacks of concentrate. Much water has accumulated in the mine, which is being brought to the surface by an air-lift, the effectiveness of which has been demonstrated. Engineers of the Oaks Company have been making mine examinations at Parsons, for Chicago people.

Mogollon, March 30.

OREGON

BAKER COUNTY

The operators of the Ben Harrison mine, situated in the Greenhorn district, have sent 200 sacks of their ore of average grade to the California Ore Testing Co., at San Francisco, to have determinations made as to the best method of treating it before building a mill. Connor brothers, owners of the Golden Chariot mine, are mining ore, and treating it in a small mill.

JOSEPHINE COUNTY

The Almeda Con. Mines Co. is making good progress in building an auto-truck road from the railroad to its mine and smelter at Galice. When this is finished, coke is to be hauled in, and the smelter will be blown in.

UTAH

JUAB COUNTY

Cyanide tests have been made on certain typical low-grade ores of the Grand Central, Sioux, and other mines of Tintic district, controlled by C. E. Loose and associates, and the Eureka *Reporter* states that, as the results have been satisfactory, a cyanide plant may be erected in the district to treat this class of ore. The May Day mill, which is a concentrating plant, is treating 50 tons of ore per day. The mill has been operated several years. The Carisa mine, in charge of Edward Riggs, is again in operation, two machine drills being in use on the 500-ft. level. The Victoria is being provided with a hoist of larger capacity, and a 6-drill air-compressor. The Victoria is producing two cars of ore per week and is being well developed. The drift on the 1050-ft. level has been extended 350 ft. in quartz.

SUMMIT COUNTY

During 1910 there was concentrated in the Daly West mill, Park City, 83,119 tons of ore, the average content of which was 7.95% lead, 8.93 oz. silver, and 8.39% zinc. F. W. Sherman, mill superintendent, figures the extraction at 97.48% of the lead, 82.8% of the silver, and 71.4% of the

zinc. The product for the year consisted of 16,123 tons of lead concentrate, containing 38.14% lead, 32.54 oz. silver per ton, and 13.06% zinc; and 7879 tons of zinc concentrate, running 5.55% lead, 17.42 oz. silver per ton, and 37.78% zinc. The lead concentrate brought $576,122; the zinc concentrate, $111,293. Important changes have been made in the mill to make it adaptable to zinc concentration.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—During the year 1910 the Republic Mines Corporation shipped 415 cars of ore, aggregating 19,360 tons, from the Surprise mine. Up to March 24 of the present year 51 cars shipped contained 1510 tons. The Imperator-Quilp company shipped during the part of 1910 that it operated the Quilp mine, 37 cars, containing 1110 tons, and this year, up to March 23, 51 cars, containing 1510 tons. In the Surprise mine the workings on the Jim Clark adit-level are in ore averaging about $20 per ton. On the intermediate level, 40 ft. deeper, the average assay of the ore is about $40 per ton. At a depth of 240 ft. the miners are breaking into the 'bonanza' shoot, the ore in which is assaying from $12 to $35 per ton. At a depth of 550 ft. the best showing of ore in the mine is in a stope situated about 200 ft. north of the dividing line between the Surprise and Quilp claims, the ore assaying $30 to $260 per ton.

Republic, March 28.

OKANOGAN COUNTY

(Special Correspondence.)—The Granby company of Grand Forks, B. C., has bonded several claims on Copper mountain, in Myers creek district, and is establishing a camp. A large force of men will be employed in exploring the property through old workings, and a diamond-drill will be employed in the exploration of undeveloped ground. The miners in the Gold Axe mine, Copper mountain, report that a body of ore 8 ft. wide has been opened in an adit which was driven to tap the vein, and the ore is of a grade that will stand the expense of shipping and pay a profit. Northeast of the Gold Axe is the property of the Cain Gold Mining Co., which is driving an adit 1100 ft. on the Jim Hill claim. A wagon-road is being made, so that an air-compressor and power-drills can be hauled in. Some gold-bearing ore was developed in a shaft before the adit was started. The adit is now in 230 ft. The company has established good quarters for its men.

Oroville, March 27.

STEVENS COUNTY

(Special Correspondence.)—The Washington-Ohio company, owning the Noble Four group of claims, covering an extension of the main vein of the Napoleon mine of the British Columbia Copper Co., and situated two miles south of Bossburg, reports having driven seven adits on the vein, from 80 to 306 ft. in length. The No. 3, of greatest length, has cut a stringer of ore, assaying 13% copper, accompanied by some lead, silver, and gold. A bond for the sale of the Big Bear mine, situated between Marcus and Bossburg, has been taken up by Spokane people, who will provide an air-compressor and machine-drills to develop and operate the mine on an extensive scale. The purchase price is reported at $5000.

The British Columbia Copper Co. has completed its cyanide plant at the Napoleon mine and made some test-runs on iron-carbonate and oxide ore for which the plant was especially built. The capacity of the mill is 100 tons per day, and its cost was $20,000. The iron sulphide ore of the Napoleon mine is shipped to the company's smelter at Greenwood, British Columbia.

Orient, March 30.

CANADA

BRITISH COLUMBIA

The British Columbia coalfields are attracting much attention this year. The sale of the Dunsmuir properties to Mackenzie, Mann & Co., Ltd., is to be followed by the opening of new collieries, both by this company and the Western Fuel Co. of San Francisco. The Pacific Coast Co., Ltd., has plans for extensive improvements. Warren R. Roberts, of Roberts & Schaefer Co., Chicago, specialists in building coal-treatment plants, recently visited the coalfields, and it is probable that one modern washer, and possibly others, will be built.

NOVA SCOTIA

(Special Correspondence.)—The Scheelite Mines, Ltd., operating a tungsten property, situated at Moose River Gold Mines, Halifax county, is to erect a milling plant for concentrating its ores, and for the separation of the magnetic from the non-magnetic metals. Victor G. Hills, of Denver, Colorado, recently appointed general manager and consulting engineer for this company, is now at the property.

Moose River Gold Mines, March 27.

MEXICO

Advices from the managers of the Mexican properties of the Mines Company of America are to the effect that while the transportation facilities have been interrupted at times, there has been no destruction of mining property or interference with operations. In fact, both the insurrectos and the Government are seeking to aid and encourage the regular operations of the large companies. Both the Mexican Government and the opposition are specifically pledged to the full protection of property rights of foreigners. Owing to the policy of carrying large stocks of supplies at the mines, the interruption of transportation has not necessitated the closing or curtailment of output of any one of the four operating mines owned by this company, which are the Dolores and El Rayo in Chihuahua, and the Creston and La Dura in Sonora.

SONORA

The Sonora Copper Smelting Co., which has developed the Cobre Grande mine within the last three years, has erected a copper-smelting plant of 100 tons capacity, which is nearly ready to operate. The property is situated three miles from Noria station, on the Nogales-Guaymas railroad. A 3400-ft. aerial tramway of the Leschen type is being erected. A. M. Conrad of Nogales is the company's manager.

(Special Correspondence.)—Martin Hickinson, owner of the San Lorenzo mine, situated 30 miles west from Cumpas, has been in El Paso arranging with the smelter for ore shipments he will make in the near future. The San Lorenzo property was, about a year ago, under option to El Paso people, but because of great distance from transportation it was given up, since when Mr. Hickinson has proceeded with the development. He has uncovered a body of low-grade copper ore, running 2.5%. In the past year he has been developing a body of high-grade ore, which averages 24% copper, 75 oz. silver, $3.50 gold, and 10% bismuth. This is the ore he intends shipping, of which there are 180 tons now on the dump. The shoot of this ore is 60 ft. long and 5 ft. wide. This ore will be packed on burros to Nacozari, thence by rail to El Paso. The burro charge is $15 per ton; but as this ore will run above $80, it will pay to ship. At the Transvaal mine, he reports a discovery by the diamond-drill of 200 ft. of solid ore. There are two deep drill-holes on the Transvaal, one 1300 and the other 1200 ft. H. C. Beauchamp is manager of this property, on which 75 men are working.

Cumpas, March 25.

CENTRAL AMERICA

COSTA RICA

J. H. Hartley of Berkeley, California, is now manager for the Compania Minera del Porvenir, at San Jose, Costa Rica. The Porvenir is said to be an interesting property. The Denver company which had an option on it failed to make final payments, and the mine reverted to the original owners. W. F. White, of New York, arrived at San Jose, March 15, and went thence to the Aguacate mines, in which he is interested. The Aguacate Mines Co. is putting up a 10-stamp mill.

Mineral Production of Colorado

Figures showing the mineral production of Colorado in 1910 have been compiled by the State Bureau of Mines and are published below, through the courtesy of T. J. Dalzell, Commissioner of Mines.

											$33,000,623.74

NOTE.—In the above table the calculations are made on the average price of the mineral for the year. Gold, 20.67; silver, .5347; lead, .0449; copper, .1263; zinc, .0539. The zinc figured on actual spelter recovered.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—MEASURE OF DAMAGES

An employee, or miner, negligently injured is entitled to damages fairly compensating him for his mental and physical suffering, loss of time, permanent impairment of money earning power proximately resulting from the injury, not exceeding the amount claimed in his petition.

West Kentucky Coal Co. *v.* Davis, (Ken.) 126 Southwest. 1074. June 1910.

REASONABLE AND ORDINARY CARE

Reasonable or ordinary care, as applied to a miner, to avoid injury by a locomotive and cars on a railroad track, operated in connection with a mine, is such care as an ordinarily prudent person will usually use under circumstances the same or similar to those proved in a similar case.

West Kentucky Coal Co. *v.* Davis, (Ken.) 126 Southwest. 1074. June 1910.

LOCATION OF MINING CLAIM—RIGHTS OF SUBSEQUENT LOCATORS

The law requires the locator of a mining claim to make his location so definite and certain that from the location notice and stakes or monuments on the ground the limits and boundaries of his claim may be ascertained, and so definite and certain as to prevent the changing or floating of the claim. And where a discovery is made on a vein and mineral-bearing rock, and the notice provides that such claim extends 700 ft. in a northwesterly direction and 800 ft. in a southeasterly direction from such discovery, and the corner stakes on the southeasterly end are so placed as to take in more than 800 ft. of such vein, subsequent locators may legally locate this excess of ground, as the first location is valid only to the extent of 800 ft. southeasterly from the point of discovery.

Flynn Groupe Mining Co. *v.* Murphy, (Idaho) 109 Pac. 851. June 1910.

LIABILITY FOR INJURY TO EMPLOYEE IN OPERATION OF A MINING RAILROAD

The employees in charge of a locomotive and cars on a railroad operated by a mining company in connection with its mine, are bound to keep a lookout for employees working near the track and to give reasonable warning of the approach by blowing the whistle and ringing the bell. And an employee in a mine working near a railway track, used in the operation and in connection with the working in the mine is bound to use ordinary care to discover an approaching locomotive and to avoid collision; but in such case whether the servants in charge of the locomotive were negligent, or whether the injured employee was guilty of contributory negligence, are questions for the jury. The rule is that the liability of a mine company for injury to an employee, caused in the operation of a railroad in connection with its mine, is governed by the rules applying to ordinary railroads; but the operator of the coal mine is not guilty of negligence in failing to equip the coal car with a fender or pilot.

West Kentucky Coal Co. *v.* Davis, (Ken.) 126 Southwest. 1074. June 1910.

Recent Publications

SUMMARY OF OFFICIAL REPORTS ON THE METRIC SYSTEM. 2nd ed. London, 1911.

ANNALES DA ESCOLA DE MINAS DE OURO PRETO. No. 10. 1908. Pp. 171. Ouro Preto, Brazil. This includes a series of technical papers dealing with the iron ores, railways, and irrigation works of Brazil.

PERMISSIBLE EXPLOSIVES. By Clarence Hall. Bureau of Mines, Miner's Cir. 2. Pp. 12. Washington, 1911. An account of the explosives tested at Pittsburg prior to January 1, 1911, and of precautions to be taken in their use; written in simple language.

SOLAR EPHEMERIS, 1911. By A. Lietz Co., San Francisco. This is an ephemeris in pocket form, containing complete tables for the determination for azimuth by observations on the sun, and also on Polaris. It forms a convenient appendix to the civil engineer's notebook.

BIENNIAL REPORT OF THE STATE GEOLOGIST. By H. A. Buehler. Missouri Bureau of Geology and Mines. Pp. 68. Ill. Jefferson City. While this is mainly an administrative report prepared for the Forty-sixth General Assembly, Mr. Buehler has included a preliminary account of the coal measures by Henry Hinds, and notes on the southern part of the State by V. H. Hughes and Wallace Lee. With these papers are hitherto unpublished maps that are of considerable value. Evidently the Missouri survey is doing good work and deserves consideration from the legislature.

DATA. This is a new monthly publication issued from 92 La Salle street, Chicago, and costing $1 per year. It bears the quotation, "Every engineer should make his own pocket-book," and proposes to aid in the making by publishing monthly on sheets of card-index size diagrams, tables, and data of value to engineers that may be filed in an ordinary desk card-file. This has much to commend it, but misses the point of the quotation. The reason why an engineer should make his own book is that by putting a sufficient amount of work into it he becomes familiar enough with it to make it really useful to him.

MINE RESCUE STATION COMMISSION, STATE OF ILLINOIS. Report to the Governor and General Assembly. Pp. 31. Ill. Springfield, 1911. In this modest little pamphlet is detailed briefly the record of a lot of good work. It will be remembered that following the Cherry disaster there was an investigation of conditions in Illinois mines as regards safety and that advanced legislation was shortly thereafter enacted. Among other things a mine-rescue commission was established. It includes representatives of the men, the operators, the inspection force, the Universities, and the U. S. Bureau of Mines. Under this commission three stations have been established for training men in rescue and first-aid work. In connection with them, cars have been equipped with men and apparatus to rush to the scene of any accident. It is pleasant to record that of the three cars one was given, fully equipped, by the Chicago & Northwestern railroad, another by the Chicago, Milwaukee & St. Paul, and the third, sold at a nominal price by the Pullman company, was equipped at the shops of the Toledo, Peoria & Western. This only illustrates the generous spirit of co-operation that has been called forth by the work of the commission. So far the rescue cars have not seen service, and it is hoped they may long remain idle. The training of men so as to prevent accidents, the real work of the commission, will necessarily be slow. Much has been accomplished by calling attention to the need and methods. In the long patient routine ahead of it the commission will have the good wishes of all interested in bettering conditions in the mines. Illinois has started a work that other States would do well to undertake.

H. F. B.

Company Reports

BRITISH COLUMBIA COPPER CO., LTD.

The annual report of this company for the year ended November 30, 1910, shows that during that time 441,672 tons of ore and converter slag was smelted, yielding 7,199,034 lb. of blister-copper, containing 24,962 oz. gold and 84,180 oz. silver, the average cost of production of copper being 9.048c. per pound. Most of the ore was derived from the Mother Lode mine, but the Wellington Camp, Oro Denoro, and Napoleon contribute about 15,000 tons each, while about twice this amount was smelted for custom work. The balance on hand is $731,265.75. The authorized capital is 600,000 shares at $5 each, of which 591,709 have been issued. The value of the properties as given in the balance sheet is $3,333,897.80.

ARIZONA COPPER CO.

During the year ended September 30, 1910, this company mined and treated 754,187 tons of ore of an average copper content of 2.13%. Of this, 559,250 tons of sulphide ore was milled with a concentration ratio of 5.14 tons into 1; 115,223 tons was treated by the oxide concentrator, and tailing amounting to 102,831 dry tons was leached, the copper production from the latter amounting to 11.3% of the total of 32,210,000 lb. of blister-copper for the year. The sulphuric-acid plant produced 2971½ tons of acid. The mine equipment and methods of work are being greatly improved; the square-set and fill method is being abandoned, and the use of electric power is being extended. In the Boulder mine 30,000 tons of 5% ore has been exposed, while in the Coronado mine there is 100,000 tons of broken ore in the stopes. In the latter property a shoot of sulphide ore averaging 3% copper has been discovered east of the main shaft on the 700-ft. level. West of the shaft on the same level a valuable body of ore was also found. This orebody is now practically exposed for 600 ft. along the vein. The ore retains its high-grade nature, the cross-cut nearest the breast exposing four feet in width of very high-grade sulphide with 12 ft. of good concentrating ore.

TEMISKAMING MINING CO., LTD.

The report of this company for the eleven months ended December 31, 1910, shows that 18,456 tons of ore was mined and 21,683 tons was milled. There was shipped 390.19 tons of hand-sorted ore of an average content of 3446.36 oz. silver per ton, and 651.77 tons of concentrate of an average silver content of 814.97 oz. per ton. The actual cost per ton of mining and development can be obtained only by wearisome computation, as the management has included over 10,000 tons of waste in computing the tonnage-cost of this work. The cost of milling was $2.54 per ton milled, and the cost of smelting the concentrate amounted to $1.31 per ton milled. The cost of hand-sorting was 55.3c. per ton of ore sorted. The total received from ore sales and shipments was $1,022,390.52, the cost of operations being $303,071.01, leaving a profit for the eleven months of $719,319.51. Of this, $22,605.63 was written off as depreciation, and $275,000 was paid in dividends, leaving a balance on hand of $431,017.56. As in the balance-sheet the value of the property is assigned as $2,421,117.73, and the equipment of the mine as $203,450, the amount set aside for depreciation is entirely inadequate; the 18,456 tons of ore extracted during the period under review represents a depreciation in the book value of the mine of $698,280, and no statement is given of any increase in the ore reserve to counterbalance this. The authorized capitalization is 2,500,000 shares of $1 each, of which 2,499,172 have been issued. A useful feature of this report is the appended drawings showing the mine-workings, the mill, and flow-sheet of the mill. A brief and lucid explanation of these would greatly increase their usefulness.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. F. McEwen, of Duluth, has gone to Nevada.

H. F. Bain and Charles Janin are at Angels Camp, California.

Frank A. Keith, of Los Angeles, was at San Francisco last week.

E. W. Carson, of Los Angeles, is making an examination in Nevada.

Charles Butters has gone to Salvador, expecting to return in June.

C. W. Purington is expected in London on April 15, from Chito, Siberia.

Morton Webber has gone to Porcupine and expects to be there for some time.

J. W. Thompson is law examiner for the Bureau of Mines, Washington, D. C.

John E. Pelton, F. W. Stall, and G. E. Hall, of National, Nevada, are at San Francisco.

Alexander H. Smith has gone to South Porcupine, Ontario, to remain several months.

Huxley St. John Brooks is metallurgist for the Major Mining Co., Benguet, Philippine Islands.

John Donaldson, secretary-treasurer of the Denver Fire Clay Co., was at San Francisco last week.

George R. Trask, of Wallace, Idaho, is in the Harshaw mining district, Arizona, making an examination.

R. Van A. Mills is at Tientsin, China, where he is professor of mining in the Imperial Pei-Yang University.

Jesse J. MacDonald has returned from an inspection of the Paradise Mining Co.'s properties, near Dagget, and is on his way to the Dale mining district.

W. H. Weed has finished the examination of the Petrazzini mine at Arizpe, Sonora, and is now examining the property of the Transvaal Copper Co., at Cumpas, Sonora, Mexico.

Andrews Allen and John A. Garcia have formed the Allen & Garcia Co., to act as consulting and contracting engineers. The offices of the new firm will be in the McCormick building, Chicago.

Marden W. Hayward, having recently completed a geological survey of the property of the Summit Copper Co., at Bellevue, Arizona, is now engaged in examining a number of mining properties in California and Nevada.

Frank H. Probert is at Ray, Arizona, looking over the Ray Central company property; in a few days he will go to Guanajuato, Mexico, to make examinations of the properties owned by the Proprietary Mines Company of America.

R. B. Lamb, of Toronto, has been in Cobalt and South Lorrain on professional work, and has left for Porcupine before returning to Toronto. He has recently been appointed consulting engineer for the Swastika mine in Otto township, Ontario.

The Los Angeles aqueduct in 1909 ordered a set of Pacific car wheels and axles, Anaconda type, from the D. D. Demarest Co. of San Francisco. These were designed especially to operate in gritty water. After a trial of more than a year the results were so satisfactory that repeat orders were given from month to month until they now have a full equipment for 120 cars. No engineering project is more carefully and economically conducted than the building of the Los Angeles aqueduct, and the result of the test given the Pacific Anaconda type of car wheels and axles speaks well for the engineering ability of the manufacturer.

TABLE OF CONTENTS

EDITORIAL

IDITAROD has been swept by fire, with a resulting loss of $100,000, and the development of this promising new Alaskan district is likely to be seriously hindered by the disaster.

DR. RAYMOND, after twenty-eight years of devoted service as Secretary of the American Institute of Mining Engineers, has been appointed Emeritus-Secretary, to afford him in his seventy-first year the leisure his labors have so richly earned. Fortunately the ripe judgment and long experience of Dr. Raymond are not to be entirely lost to the Institute for many years, we hope. The Council has appointed Mr. Joseph Struthers, who has served as Assistant Secretary and Editor, to the position made vacant, and he will take up the work which the veteran Secretary has laid down.

THE RAND has paid dividends more substantial than those in coin. Mr. J. H. Dobson, in a valedictory address before the South African Association of Engineers, discusses at length the novel problems that presented themselves in the development of the art of mining and treating the deep-level ores, and the means by which the ingenious and capable engineers of the Rand accomplished their resolution. The roll of those who have made history in South African practice is a long and honorable one, and the Association may well pause for an hour to review what has been accomplished and to survey what still remains to be done.

IT has long been the fashion among leaders of finance in New York to ignore the fact that the gold in their vaults, the very basis of their monetary system, is the direct result of mining industry, and to treat with scorn all mining enterprises as being too highly speculative to be worthy conservative consideration. It is exceedingly interesting to watch the development of interest in the new gold camp of Canada. The 'big board', as the New York Stock Exchange is called by Wall Street, has always frowned upon mining investments, possibly because that body has believed that all of the money diverted into mining enterprises represents an equal amount lost to the Exchange. Now, however, trading has dwindled to such small proportions that even the New York Stock Exchange is welcoming the activity that has sprung up in Porcupine shares, as an evidence that there is a public that may be interested if the appeal is strong enough. The attitude of the Government in raiding various houses engaged in fraudulent promotions, and the strong intimation that newspapers carrying advertisements of such schemes were no

better than the promoters, has evidently had the effect of quieting the newspaper support for the Porcupine boom. Porcupine has continued to gain ground, but that the movement is largely psychological is shown by the growth of the excitement, for the most part, without any basis in actual news.

A RECENT REPORT of the Denver Chamber of Commerce on the mining industry of Colorado calls attention to the solid foundation upon which the industry is based, and concludes with the assertion that "the two great enemies of the mining industry are: (1) that class of promoter whose ability does not extend beyond separating other people from their money; (2) inexperienced, inefficient management." The former can be reached by legal means, but the campaign against the latter must be one of education, and every recruit to the forces that are making toward the placing of the business of mining in a sound and healthy state is welcome.

SCRANTON, Pennsylvania, will certainly have the best professional advice in settling the mine-cave problem. Messrs. William Griffith and E. T. Connor having studied the conditions for four months, the whole situation was recently reviewed above and below ground by an advisory commission including Messrs. John Hays Hammond, D. W. Brunton, L. D. Conkling, H. S. Drinker, Charles Enzian, J. A. Holmes, J. F. Kemp, W. A. Lathrope, J. F. McClelland, G. S. Rice, H. L. Smythe, and Lewis B. Stillwell. We understand that a preliminary paper will be published now, but that the United States Bureau of Mines will undertake some further tests before the final report is made.

PHILIPPINE dredging has not yet been particularly profitable to stockholders, if we may judge from the experience of the Paracale Gold Dredging Company. The net bullion returns on this enterprise in 1910 are given as $55,000, and there was some dissatisfaction among the shareholders at the absence of dividends. The teredo, it seems, ruined one hull, and a new one had to be built and protected by sheathing. The enterprises so far launched in the Paracale district are small. Just what could be accomplished with a large California dredge and resulting low working-costs is unknown. Probably the Philippines will have to pass through a period of small, expensively operated dredges, as California did, and the Nome district is doing, before a really large boat will be built in that district.

EXPERIMENTAL work in the mine as well as at the testing station is being conducted by the United States Bureau of Mines. In an interesting paper read before the Western Society of Engineers, April 5, Mr. George S. Rice, chief mining engineer of the Bureau, gave details as to the plans and purposes of the experimental mine recently opened near Pittsburg. Since explosive force travels through a mine in waves, there is distinct promise of finding a method of localizing any explosion. If Mr. Rice and his associates succeed in devising means of quarantining against blown-out shots, the achievement will rank with the discovery of means of controlling yellow fever. We are glad to see that the work at Pittsburg is standardized with that of the Canadian and European stations, thereby avoiding waste and duplication.

WISDOM and folly often come into conflict, and wisdom by no means always gets the best of the encounter. Now that science and fashion have warring interests in the platinum industry, it is extremely likely that science will be the one to suffer. For some years past the use of platinum in jewelry has been growing, and more recently a jewelers' association has been endeavoring to make it the metal of fashion for the coming year. Platinum is as necessary a commodity of scientific work as food is of the scientist's life; the price has always been so high as to constitute a serious burden on scientific research, and has recently nearly doubled. With the output of the present source of supply steadily decreasing, and the discouraging results of extended search for other deposits, the present tendency to increase the use of platinum as a decorative metal is much to be deprecated. The color of platinum is not so pleasing as that of silver, and the only advantage it possesses over the latter metal is that it does not tarnish. Public protest is unlikely to have any more effect than did the wielding of Mrs. Partington's broom. Apparently the only ray of hope left for the scientist is that a satisfactory method of making utensils of platinum plated-ware may at last be found.

Recklessness Again

Little more than a month ago we recorded the story of the disaster at Tonopah—a great matter kindled by a little fire, underestimation of danger, unpreparedness, and heroic efforts when attention and effort were too late to be of avail—and pointed out how similar it was to that at Cherry, Illinois, a year before. Now comes the story of Throop, Pennsylvania, where a small fire started in an engine-house at the opening of a slope leading from the Diamond seam, seven hundred and fifty feet from the surface. There were four hundred men at work in the mine, sixty of them in 'blind' workings at the end of the slope. The fire was discovered at nine o'clock in the morning, but no attempt was made to get the men out until eleven o'clock. By midnight seventy-three were dead, including John Evans, engineer in charge of the Bureau of Mines rescue car which had hurried to the scene. Only telegraphic accounts of the disaster have yet been received, but one lesson stands out plain: the grave responsibility which those in authority incurred in not promptly notifying the miners of the existence of possible danger. To have brought the men out early in the day might have resulted in the interruption of a shift's work for a very slight matter; leaving them at work has resulted in a long roll of dead. It is a national characteristic, this recklessness of danger. The small boy steals rides on street-cars and railroad trains, the grown man takes chances equally great, while many regard their actions with approval,

as exhibiting a virile and courageous spirit. It is easy to show the error involved in such a mental attitude, while the taking of chances with the lives of others as the stake is criminal. We get too business-like sometimes. The thoughtful address on 'The Balanced Life,' in our issue of February 18, lays stress on the responsibilities which no manager can escape. It would be well if every manager would take these lessons to heart.

Concrete

On another page Mr. Del Mar presents a discussion of the increasing use of concrete in mill and smelter construction. This is a recent development that promises to be so far-reaching in its effects that any discussion of it must necessarily be from many different standpoints in order that we may obtain a comprehensive view of the whole. Perhaps the most striking of its salient features is the probable effect upon the development of forestry. The great demand for timber for the enormous amount of construction work which had been created by the rapid development of our industries during the century past, has made serious inroads upon the forests of our country, and their impending destruction brought in its train questions of serious import to the National life. These have now been largely met by the increased care of the forests and the lessened demand resulting from the increased use of concrete. Of only slightly less importance from the standpoint of commerce and industry is the converting into valuable assets of the deposits of clay, shale, and limestone which until the advent of cement manufacture were almost worthless, but now have, in many cases, become the basis of great industries.

A most natural mistake in the development of a new method or material is the attempting to use it for many purposes to which it is unsuited, just as the small boy goes about with his new jack-knife, trying it on window-sills, doors, and on objects of metal and stone. It must be remembered that concrete is not at all suited to the construction of any building or other structure that is at all likely to require extensive alterations or to be temporary in its nature. When a prospector comes to a new gulch he does not proceed to erect a brick house: he puts up a tent, so that he may move on quickly and with little expense if the results of his prospecting prove unpromising. Even where ore-dressing mills have been so carefully designed and upon such reliable experimental data as in the case of those of the Nevada Consolidated, the Ray Consolidated, and the Miami, changes are at times necessary for the simple reason that no man can be sure of what he may want to do next year. In the case of ordinary small-sized mills the changes that the experience of actual operation proves necessary are often radical and sweeping. Wooden structures are quickly and easily altered, the old material often being of much use in the new arrangement, but concrete structures require much effort to change them, at correspondingly great expense, and the old material is frequently entirely useless. A timber foundation, for example, can be altered by the use of a saw and hammer, but to remove a concrete foundation dynamite is often the only effective agent, and unless the machinery is moved to a distance the effect upon it is likely to be disastrous. The razing of the seven-story reinforced-concrete building of the Baltimore *News* has called attention to this limitation to the use of that material and to a possible danger which is more seriously regarded in England than in this country. The strength and durability which make concrete a desirable material for many structures are distinctly undesirable qualities in a structure, or part of structure, which may soon require alteration or removal. The danger referred to is the possible rusting of reinforcing steel. While the steel in this building was in general in perfect condition, it appears that wherever any amount of water came into contact with the concrete, as in the roofing slabs and the floors of rooms containing shower-baths, a certain number of rust-pits were found. The concrete was apparently of good average quality, and the fact that no dangerous rusting had occurred may be due only to the short life (six and a half years) of the concrete. Possible protection against this danger is suggested by the good condition of the steel in the footings. These are below the ground-water level, but the greater thickness of concrete seems to have prevented rusting.

These are but two of the problems now under consideration by engineers concerned with, or interested in, the use of concrete. Among the more important and interesting of the many others are the increase in density and decrease in permeability of concrete by grading the sizes of the aggregate; the water-proofing of concrete; the effect of alkaline and other impure waters during and after setting; and the hydra-headed question of reinforcement—percentage, form, and position. Volumes have been written, and more will be written, before these questions can be answered with any authority, but a few practical conclusions have been reached. By screening the aggregate and mixing the different sizes in proper proportion, a mixture of one cement to ten aggregate may be as dense and rich as an ordinary 1–2–4 mixture, as has been shown in practice in construction of the new swimming pool at the University of California. A fairly dense concrete may be made practically impervious by adding powdered alum and ground clay, in almost any proportion not exceeding five per cent of the cement. Soap and alum have also been used with success, on the theory of the well-known Sylvester process of water-proofing brick-work. The effect of alkaline water is uncertain, and may depend on the characteristics of the cement and aggregate used, but is undeniably harmful in some cases. Any water containing salts which may be deposited as crystals will scale the surface of any but the densest concrete. A small proportion of clay or silt in mixing-water is not dangerous, unless organic matter is present. Acids, of course, are always dangerous. It would require a volume to even indicate the questions of reinforcement, but the chief difficulty in their discussion seems to arise from the lack, as yet, of reliable empirical data on which to base theoretical reasoning.

Modern Zinc Problems

By H. Livingstone Sulman

*In no department of metallurgy has development been more rapid than in the treatment of 'complex ores.' Just as the terms 'free milling' and 'refractory', as applied to gold ores, have lost their older significance, so a few years hence the word 'complex' will cease to be used as a prefix to zinc-lead-silver-copper ores, and as a reproach to reduction practice. Their treatment will, in the main, become normal, in the sense that each constituent metal will permit of the profitable recoveries now possible with its simple ores. Many millions of tons of such material have been found, and in some instances partly developed, whose contained metals at current prices render them equivalent in value to two-ounce gold ore. The importance of this outlook is now realized, and capital is being invested in such deposits with the assurance of their great ultimate value. The 'complexity' is due to the presence of blende, generally more or less ferruginous, in intimate physical association with galena and other minerals, but varying considerably in degree. It is unnecessary to detail the varying characteristics of the many typical complex ores, and I content myself with brief reference to one or two.

Most lead mines are also blende producers, and, similarly, every zinc deposit carries lead. When dressing operations suffice to yield the major part of the lead as a galena concentrate, and a substantial zincblende product, carrying from 45 to 50% of metal, the ore is not 'complex'; the lead mines of Cardigan, Cumberland, and Joplin are familiar examples. The finer or slime products from the crushing and dressing of such ores are still, however, complex, in the sense that the mechanical, or, indeed, other separation of an intimate mixture of blende and galena, still awaits a satisfactory solution. The Broken Hill deposits, with their intercrystallized galena and ferruginous blende, with the rhodonite and garnet gangue which formerly prevented the separation of the zinc, are now of decreasing complexity; and from being material affording but 16s. profit from £8 worth of metal content per ton, their tailing accumulations have, through the application of flotation processes, become a substantial source of supply for the world's zinc.

The slime reserves, however, still present considerable difficulties in treatment. A more truly complex problem (though on the eve of solution, if not indeed already solved) is that which occurs in the great deposits on the west coast of Tasmania, typified by the Rosebery and Mount Read ores. Their metallic contents are of somewhat higher value than those of Broken Hill, while the presence of copper adds to their complexity; the difficulty in this instance is that the ore contains but little gangue, say from 7 to 15%, its place being taken by pyrrhotite and pyrite intimately intercrystallized with blende and galena, the whole constituting massive mineral. Proximate methods of separation are therefore useless, and flotation could at best only concentrate 10 parts into 9, and with but incomplete separation of the individual sulphide minerals. Successful means of reduction must be sought in other directions, either by direct smelting, hitherto inefficient, or the removal of the zinc from the roasted ore by leaching processes, leaving the residue, carrying the lead, silver, and copper, to be dealt with by the smelter; such methods appear to promise well.

The San Francisco del Oro mine supplies another type of complex ore, one difficulty being the presence of a large proportion of fluorspar in the zinc concentrates, which render them unsuited to retort distillation. It is hoped to treat them in the De Laval electric zinc-furnace. As an example of an oxidized complex ore the zinc-lead carbonates, etc., of Rhodesia Broken Hill will be recalled. The variety of such ores is thus great, and while the main factor of difficulty, zinc, is surmountable in several ways, it is not to be supposed that any one process will attain to pre-eminent success with each and every ore-type to the exclusion of other methods.

Reviewing the various means by which such ores may be attacked, they appear to divide themselves into two broad classes—proximate or mechanical methods, and ultimate or leaching and smelting processes. Proximate methods are necessarily subject to the limiting conditions imposed by the crushing of heterogeneous material, and therefore to the possible complexity of even the fine particles. While generally cheaper in application than the ultimate method of hydrometallurgy, they involve less complete separations, and often the marketing of several grades of product, or loss of profit when by admixture these are sold as a single grade. Where both types of method are applicable there is the possibility of keen competition between them, and the final advantage can only be determined by the balance-sheet. Among proximate methods 'flotation processes' have rapidly come to the front, greatly modifying previous metallurgical practice; these are also referred to somewhat indiscriminately as 'oil' and 'surface-tension' processes. While all depend upon the molecular forces, small in range but of high intensity, which are exhibited at the surface of both solids and liquids, their mode of utilizing these forces varies considerably.

The simplest type is represented by the De Bavay process, used in the treatment of the zinc tailing or 'middling' by the Amalgamated Zinc Co. at Broken Hill; and by the 'Macquisten tube' employed at the Adelaide mine for the concentration of chalcopyrite from vanner tailing. In these, the surface-tension of water is used to float off the sulphide particles, which are not readily wetted, whereas the more readily wetted gangue particles sink, when a mixture of both is suitably presented to or upon a flowing water surface. Bradford, in 1885, was one of the first to use such a method for sulphide mineral concentration, but its application to the grading and cleaning of graphite has long been known and practised. The principle upon

*Presidential address delivered before the Institution of Mining and Metallurgy, March 22.

which these processes are based is seen in the tendency of a pyritic or gold tailing to float away during a hand-panning operation. None of these methods claims the use of oil in enhancing flotation, and they appear to be limited to separation of particles of sensible size, for the reason that slime particles in suspension offer great mechanical difficulties in their presentation afresh to a water-air surface.

A second variety is the Potter process, employed at the Proprietary mine; in this method, submerged mineral sulphide particles are caused to rise to the surface of a hot acidified pulp by the fixation of gas bubbles; the gas in this instance is carbon dioxide generated by the hot acid from the siderite contained in the ore. Calcite appears to be of little value in this particular case.

The third variation includes the well-known 'oil' processes of Elmore and Minerals Separation, Ltd., which secure the flotation of submerged mineral particles by means of bubbles of air, such particles having previously received a slight film covering of oil for the purpose of effecting the air or gas attachment. With flotation processes designed to raise submerged particles to the surface by means of gas it is apparently necessary for the gas to be generated in the pulp itself. Elmore effects this by liberating the air dissolved in the water by means of a vacuum; Minerals Separation accomplishes the same object by vigorous agitation and supersaturation of the pulp with air. The oil film used by both is for the better attachment of gas generated from solution, or, in figurative language, for cementing the oiled particle to the air bubble.

It will be obvious that these modified oil processes differ essentially from older methods in which metallic particles were brought into contact and held entrapped by sensible bulks of oil, the whole then being removed and the mineral recovered therefrom, although the somewhat obscure physical reactions by which the oil attaches itself preferentially to sulphide minerals, and water to gangue, are still utilized to the full. In place of the phrase 'preferential oiling to mineral,' it would be more correct to define these processes as dependent rather upon the 'preferential wetting' of gangue by water; and it is to surface energy of the various particles in regard to the liquids they preferentially attach, rather than to the surface tensions of these liquids, that we must refer the phenomena.

The use of oil for collecting or separating certain metals and minerals from worthless gangue is ancient of days. It is mentioned by Herodotus, in 'Melpomene' (194—IV), where he states, "* * * near them (the Carthaginians) lies an island called Cyraunis, 200 stadia in length, inconsiderable in breadth, easy of access from the continent, and abounding in olive trees and vines. They add that it contains a lake from the mud of which virgins draw up gold by means of feathers daubed with pitch"—an altogether charming vista. Two thousand years later Haines (in 1860) mixed ore powders with various fatty and bituminous substances, and thereafter kneaded out the gangue from the mass in hot water. Several others introduced modifications into this crude method. Robson was the first to wet the ore with water before adding the oil and mixing, while to a metallurgist of the fair sex, Miss Carrie Everson, we owe the important discovery that acidification of the ore pulp is necessary for the sharp oil-differentiation of mineral from gangue. It is, however, to the Messrs. Elmore that the undoubted honor belongs of first bringing oil-mineral processes into the region of commercial applicability and of securing the first success therein; their work focused the attention of metallurgists upon the great possibilities of these methods. That their original process has since been superseded both by their own later work and by that of others, cannot detract from the credit due to them as being the practical introducers of 'oil-separation' methods, and this will not be forgotten in the history of metallurgy.

To Froment, and especially to Cattermole, we are indebted for the next important development. The latter first demonstrated the efficiency of a very small quantity of oil in place of the large bulk hitherto employed. He used it to cement the mineral particles together into small shotty granules which were then capable of separation from the barren sands in a water upeast. Modern oil processes owe much to his researches, though, as is natural, further advances resulted in again reducing the quantity to the exceedingly small amounts now commonly employed for securing adhesion of gas or air to submerged mineral particles. The minuteness of the quantity of oil required to secure this result is remarkable, amounting as it does in some instances to but a few ounces to the ton of ore, which may carry 50% of its weight of mineral. Calculation demonstrates that the necessary uniform oiling of the countless millions of sulphide particles produced by the crushing of half a ton of friable mineral through a 60-mesh screen implies a thinness of oil film which approaches the lower limits of molecular attraction, being of the order of some 20 micro-millimetres, or considerably under the millionth part of an inch; such dimensions are far below the range of vision of the most powerful microscope.

The physical reactions which underlie all such methods have been insufficiently explored, and in many respects are still obscure; the striking practical results so far achieved have been reached quite empirically. I may perhaps be permitted to mention a new fact in relation to the measurement of the 'contact angles' which exist between the surfaces of aqueous liquids, and those of certain sulphides, silicates, and other solids. In investigating previously accepted figures for these, G. W. Thomson and I found a series of curiously discrepant readings, which on further research proved to be due to the existence of a variable range of the contact angle between various liquids and solids, though of constant magnitude of variation for each. This range of angular variation has been termed by my friend, C. G. Lamb, 'the angle of hysteresis,' and its existence and magnitude in regard to many substances have been independently con-

firmed and quantified by A. Howard Higgins. It is not a fact of merely academic interest, as it appears to be intimately connected with the ability of a given solid to condense upon itself a gas film; and when submerged in a liquid to determine the attachment of a gas when generated, or on the point of generation, from solution. It follows that angular hysteresis reaches its highest values for minerals which are the most susceptible of flotation, and *vice versa*. Some hundreds of observations have been taken, under the microscope and by lantern and screen methods whereby this relationship has been placed beyond doubt. Besides roughly quantifying the gas-condensing power due to the surface energy of solids, it brings us somewhat closer to an explanation of the efficiency of acidification. Thus, whereas the angular hysteresis of silica in plain water may exceed 30°, thus indicating that substance to have a definite power to occlude gas and to float, it drops from 4 to 0° in water acidulated with sulphuric acid. Galena, on the other hand, retains its full measure of angular variation, or is but slightly affected.

Returning to the practice of the various flotation processes at Broken Hill, the Zinc Corporation at present employs both Elmore and Minerals Separation systems, while the latter is also in use at the Central mine. The general result so far is the recovery of zinc concentrate, which, according to the process adopted, and the after treatment of the concentrate, may vary from 44 to 49% of zinc, together with substantial values in lead and silver. The latter minerals are in some cases partly removed by subsequent vanning, but even thereafter the main zinc product always carries a considerable amount of both—to the extent of 8 to 10% of lead, and some 11 to 13 oz. of silver. These concentrates are bought by European smelters, and are mainly shipped to the Continent for reduction. Taking the Central mine as an example of what is now being done with these hitherto refractory ores, and as dealing with sulphides originally containing 16.5% lead, 18.5% zinc, and 13 oz. silver, the final tailing from the flotation plant (exclusive of slime), amounting to half the weight of the ore, carrying but 5% zinc, 2.5% lead, and 3 oz. silver; this is equivalent to recoveries of 90% of the lead, 84 to 86% of the zinc, and 88% of the silver of the whole. This mine alone now supplies one-tenth of the world's total zinc requirements. The cost of the flotation process here employed is about 6s. per ton, including recrushing and payment for water. One reason for the ready sale of the concentrate is its uniformity of tenor, varying scarcely 1% in zinc per annum, a fact of obvious advantage to the zinc smelter.

They can at present, however, only imperfectly separate the floated minerals from each other, and the sale of their concentrate permits realization on but a portion of the lead and silver carried therein, owing, in turn, to the inability of the smelters to more than partly recover them. Indeed, the separation of the lead from the zinc in these concentrates could be pushed somewhat further than is practised. This is due to the zinc smelter requiring a certain proportion of lead to aid in the recovery of the silver, as prills of low-grade bullion, from the residue left after distilling the zinc. The method of recovery is by washing, that is, water concentration of the seconds, and is very generally practised on the Continent, and often in South Wales.

While certain difficulties yet remain to be solved, especially in regard to blende and galena slime—for it must be remembered that most of the methods referred to result only in the separation of sulphide particles of sensible size from the gangue—the Broken Hill problem may be regarded as solved, to the extent which proximate methods as yet permit, by the advent of flotation methods.

The zinc industry has undergone a marked change of late years; with the gradual exhaustion of calamine supplies, and even of the richer blende ores, and to the increasing demand for spelter, sulphide ores are now readily purchased which earlier would have found a poor market. It is not long since 50% of zinc in a blende product was a standard which admitted of little reduction. Smelters will now readily buy 45% and even 40% blendes if they contain other metals to recoup the loss due to decreased zinc: but such foreign metals are naturally paid for at a low price, from the incompleteness of their final recovery. That these secondary sources of profit may nevertheless become substantial is evidenced by the fact that, whereas concentrate was a short time since subject to penalty for shortage of zinc below a certain figure, and the producer therefore did his best to increase the zinc tenor and to decrease that of lead and silver, he is now in the curious position of being penalized for zinc above a certain limit, when this involves what the smelters consider to be an undue absence of silver and lead, in connection with a given smelting charge. This applies particularly to Broken Hill concentrate.

(*To be continued.*)

MARCH COPPER MARKET

By Misha E. Appelbaum

The copper market during the month of March fluctuated between 12⅜ and 12¼, delivered thirty days. The buying was still of a hand-to-mouth nature, the principal demand coming from the wire-drawers. The export deliveries were 59,000,000 lb., and the domestic deliveries were 66,000,000 lb., and if the production had been at the same rate as during the month of February there would have been a decrease in a visible supply; however, with a production of 130,000,000 lb., there was an increase of 5,000,000 lb., and while the quantity in itself is not large, yet the large production offers very little inducement for the consumers to buy more liberally than in the past. The general business conditions are quite below normal, and therefore, unless there is a sharp improvement in business, or a radical curtailment in the production takes place, the best one can hope is for copper to remain steady at the present level of prices.

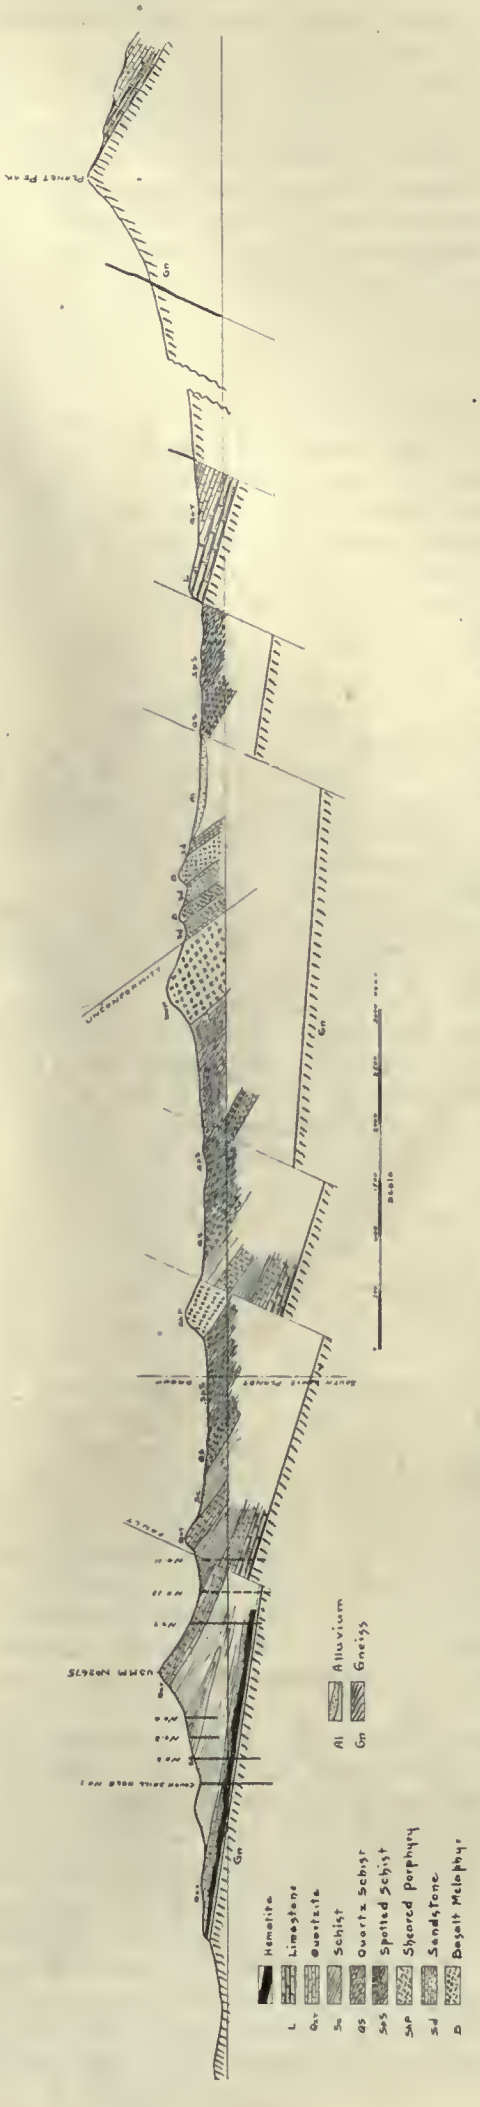
Specular Hematite Deposits, Planet, Arizona

By W. E. Upham

The Planet mine, situated in western Arizona, on the south side of the Bill Williams river, twelve miles from its confluence with the Colorado, has become quite familiar to those interested in mining affairs during the past fifty years, because of its extensive deposits of specular hematite, and of particular interest to copper operators because of the abundant association of silicate and carbonate of copper with the hematite. Deposits similar to those at Planet are rather frequent in the west-central part of Arizona, and many an engineer who has been called upon to give an opinion as to the possibility of their economic exploitation for copper or iron has been much perplexed by them. To the prospector searching for the indications of large and valuable deposits, the conspicuous outcrops of the hematite and copper minerals immediately suggest gossan, and the silicious hematitized and copper-stained croppings are reasoned to have been derived from a pyrite deposit, carrying copper, with a possible chalcocite zone of secondary enrichment.

Conservative engineers have also been prone to take a similar view of these deposits, and on the basis of favorable opinions several attempts have been made to develop them, prominent among which was that of the past year at Planet, where operations were undertaken to discover and delimit the expected pyrite ore by means of churn-drills aided by shaft-sinking and cross-cutting. None of the attempts have yet succeeded in proving relationship between the specular hematite and pyrite deposits. Nor does a close study of all the evidence available in the Planet district tend to support any theory of derivation from pyrite.

Geology.—The rocks of the Planet district, as well as a large part of this portion of the Territory, are very old. The Bill Williams drainage basin exposes the Archean complex, from which, east of Planet, erosion has left but patches of Proterozoic (Algonkian) rocks, and truncated their upturned edges in the immediate vicinity of the mine. The Archean erosion surface has lost its continuity through faulting, but nowhere in the immediate vicinity of Planet do exposures show the upper contact of the fault blocks of Archean rocks to be inclined more steeply than 7 to 9°. Local dips of the contact of Proterozoics with Archean rocks appear to be southwest, while the regional dip of the contact is northwest, the Proterozoic rocks disappearing in that direction beneath flat-lying beds of sandstone and lava flows of much more recent age. Section No. 1 shows a vertical section taken from Planet peak to the Bill Williams river, a distance of about eight miles, direction N.2°W. magnetic, cutting across the mining property of the Planet Copper Co. The faulting of the Archean gneiss, as hypothetically indicated, gives a basin-like structure to the district. It is probable that all of the

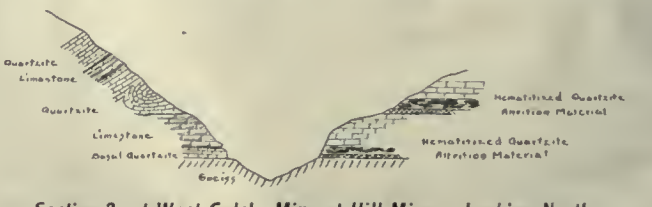


Section 1, From Planet Peak to Bill Williams River. Looking N. 88°. E. Magnetic.

upper contacts of the Archean fault blocks are comparatively flat-lying, as shown, while the Proterozoics have been tilted up into steeper positions, approximately as shown, by lateral thrusting, which has occasioned thrust faults and folding.

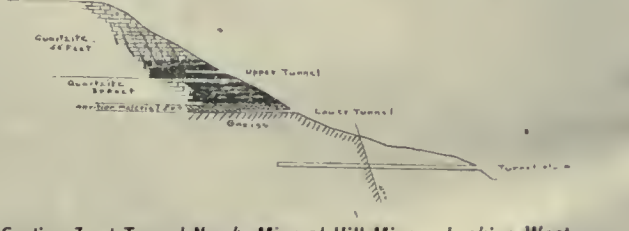
Considerable difficulty is experienced, at first sight, in acquiring a working acquaintance with these old Proterozoics, due to their extreme metamorphism and physical disturbances. Of the latter, besides disturbances due to thrusting and folding, removal of entire beds from areas represented entirely, or in part, by the tops of certain fault blocks, through leaching processes, has caused uneven subsidence of, and consequent shattering and crushing in, overlying strata. Where the leaching processes have been most active (as at the north exposure of gneiss contact, section No. 1) the basal parts of the Proterozoic rocks have been greatly affected and the apparent sequence of sedimentary deposition obscured. A section where such leaching action has been at a minimum is obtained in the west gulch at Mineral Hill mine, three miles west of the U. S. M. Mon. No. 2675 at Planet. This section is exhibited by section No. 2. The west side of the gulch shows Archean gneiss overlain by a basal quartzite (more properly arkose) 8 ft. thick. Overlying this occurs a lower limestone bed 10 to 15 ft. thick, followed by quartzite with schistose tendency, upper limestone bed 4 to 20 ft. thick and again quartzite grading into quartzose schist. On the east side of the gulch it is seen that where leaching processes have been active the basal quartzite (arkose) and lower lime beds have disappeared, their places being taken by the clayey residual matter of both beds. The upper lime bed has also disappeared and its position only recognized by an attrition material resembling indurated red sandstone. This has resulted from the intimate mixture and metamorphism of such clayey matter as was left by the limestone, and quartz sands from the leached upper part of the next lower quartzite, the processes introducing hematite. The complete removal of the lime beds and basal quartzite (arkose) is again noted in section No. 3, taken about 1200 ft. east of north of section No. 2. Here the gneiss is overlain by attrition material 5 ft. thick representing the metamorphosed residual products of the basal quartzite (arkose) and lower lime bed. The position of the upper lime bed occurs just below the upper tunnel, bottoming the upper 55-ft. quartzite bed. Its position is marked by 15 to 18 in. of material resembling indurated red sandstone (not indicated in the sketch).

A study of sections No. 2 and 3 simplifies the estimation of the basal parts of the Proterozoics at their northern exposure at section No. 1. Here the gneiss is overlain by varying thicknesses of clayey matter (1½ to 4 ft.), representing all that is left of the basal quartzite (arkose) and its overlying lime bed. A quartzite bed, largely replaced by specular hematite, follows. The sketch shows this to be quite continuous, but as a matter of fact in places this bed has been entirely leached out, leaving behind only the hematite which formerly partly replaced it. Again following is a series of quartzose schists (Sc) varying from greenish quartzites through greenish to grayish schists, with recurring variations, to a quartz schist (QS), this being a quite uniform and distinctly noticeable bed of white quartz schist. Characteristic of the Proterozoic age, the two following members are probably interbedded intrusive sheets, the lower a quartz-porphyry now mashed and sheared to a gray-colored, spotted schist (SpS), and the upper a sheared quartz-porphyry (ShP), red in color, due to the liberation and oxidation of the iron of its ferromagnesian minerals. The truncated edges of the latter form the bold, red ridges running in a parallel direction across the country, east and west,



Section 2, at West Gulch, Mineral Hill Mine. Looking North.

south of the Planet mine, and, not without reason, may be easily mistaken for porphyry dikes. Next, following an unconformity, is a series of basalt sheets, interbedded with loosely constructed sandstones with conglomerate phases. South of these,



Section 3, at Tunnel No. 4, Mineral Hill Mine. Looking West.

faulting and erosion have brought the more metamorphosed Proterozoic and Archean gneiss again to the surface.

Source and Manner of Deposition of the Hematite.—Referring to section No. 3, if it were continued back toward the south it would be found to cut through added thicknesses of a green quartzite, with schistose tendencies as variations, until a total thickness of 500 to 600 feet obtains. The exposed surface of this quartzite appears to be leached in circular or elliptical areas to a generally reddish colored quartzite or quartzose schist, which, upon close inspection, is found to be light gray in color with zonal red coloration due to deposition of red hematite along fissures which carry thin veinings of specular hematite. From the top of the series, and especially in the leached zones, the amount of the specular hematite fingering increases until the base of the series is reached at the upper tunnel, where the quartzite has been almost entirely replaced by specular hematite for a thickness of about 15 feet. The quartzite bed between the upper and lower tunnels is also largely replaced by specular hematite.

Specimens from the green and adjacent leached quartzite were taken from the part of the surface showing leached areas, before spoken of, for analysis

and microscopic examination. Rock section No. 1 is of green, unleached quartzite, and shows the rock to be a metamorphosed clastic rock composed of water-worn quartz grains, somewhat attacked by leaching action, with interstitial filling of chlorite. The rock from which this section was taken analyzes 7.02% metallic iron. Rock section No. 2 is of light-gray, leached quartzite. It shows a metamorphosed clastic rock with water-worn quartz grains with interstitial spaces incompletely filled by secondary quartz, the rest being in open spaces representing a condition of increased porosity. Hematite lines the open spaces in part and is incorporated with the secondary quartz, but scarcely in sufficient quantity to influence the light-gray color of the rock. The rock from which this section was taken analyzes 0.5% metallic iron.

The chlorite, then, of the green quartzite, appears to have furnished a large percentage of iron which has migrated in the leaching process. This migration has been by way of fissures, downward through the rock, leaving trails of hematite, as the ferrous solutions have encountered oxygen, until the base of the series was reached, when the conditions were such that complete oxidation took place and the hematite metasomatically replaced the quartzite. While a replacement of limestone by the hematite is frequently to be observed, still it is only too apparent that the limestone has acted the part of an unwilling host, while the quartzite has accepted the intrusion readily. The replacement of the quartzite by hematite is to be considered the primary concentration of the iron. If the quartz remnant of the partly replaced quartzite be completely removed without accompanying hematitization, then a secondary concentration is accomplished. In this manner the granular specular hematite deposits of the Planet mine have been derived. Since veins of specular hematite occur from the top of the spotted schist, down, it is probable that the ferromagnesian minerals of the original quartz porphyry, from which the spotted schist is derived, played their part in supplying ferrous iron to migrating solutions.

Relation of Copper Mineralization to the Hematite.—Chrysocolla (silicate of copper) appears as the most abundant copper mineral at, or near, the surface. With it is usually associated some malachite (carbonate of copper). Very rarely, small veinlets in the quartz schist carry still unoxidized copper-bearing pyrite, and at times the veinlets exhibit concentration of the copper by chalcocitization, when surface erosion has exceeded oxidation in the more impervious parts of the schist. As with the hematite, the copper-bearing solutions have been capable of replacing quartzite. This appears quite generally where hematitization has occurred and very frequently where it has not. Where the hematite is indurated and capable of being fractured, invariably the copper, as silicate, is found to fill the fractures. This general relation affords clear evidence that the movement of the copper-bearing solutions, in the main, has been subsequent to the hematitization. The source of the copper is doubtful. It is probable that igneous intrusive or extrusive sheets later than the unconformity indicated in section No. 1, now eroded, was the source of supply, the migration being effected by downward-percolating solutions. The whole series of the more metamorphosed Proterozoic rocks is cut by small copper-bearing veins, replacements by copper minerals taking place more generally in the quartzite beds (Qzt) and in the quartz schist (QS).

Relation of Pyrite Mineralization to the Hematite.—Pyrite is much more conspicuous by its absence in the Planet district than by its presence. It is true that sparsely disseminated pyrite does occur, and considerable importance has been attached to the fact that some of the dissemination has been within the specular hematite itself. In this case the hematite is to be considered simply as a basic rock with a rôle only less varied than that of any more complex rock because of its simple and exceedingly stable character.

Re-Soiling Dredged Areas in Victoria

In response to the request of A. C. Veatch, chairman of the Land Classification Board of the Department of the Interior, for information as to what is being done to re-soil dredged areas in Victoria, E. H. Goodenough has made a report, the following summary of which is given in the *Australian Mining Standard*. The regulations governing the dredging industry in Victoria provide that where the top soil is more than 2 ft. deep it must be advance-stripped to a depth not exceeding 7 ft., conveyed in a dry or moist condition, and deposited evenly on top of the coarse material. Where the soil is less than 2 ft. deep, as much of it as possible shall be spread over the surface. Difficulty is experienced in complying with these regulations.

At the Collegian dredge, working near Bonnie Doon, the appliance in use for replacing the soil is a chute made of sheet iron ⅛ in. thick. The total length of the chute is 80 ft., its breadth 46 in. across the top, and its depth 18 in., having curved or rounded sides and bottom, and when being utilized lies inside of and along the whole length of the ordinary timber sluice-box. With the full length of the chute in use it delivers the earthy material 27 ft. beyond the end of the wooden gold-saving sluice-box. The chute is made in four sections, the upper one, 20 ft. in length, being removable, and this is hung up clear of the sluice-box when dredging of gravelly wash is in progress. The next section is hinged at its lower end so as to admit of its upper end being raised out of the way when not required for re-soiling. The next length is fixed, and the last piece, 8 ft. in length, is on a hinge at its upper end, thus allowing it to be turned up when not in use, and lowered again into place when required to carry the soil to the farthest possible distance from the face. The upper section, 20 ft. in length, when in position for re-soiling, has a pitch of 3 in. to the foot, and is so placed that the top end nearly touches the lips of the buckets as they revolve. The rest of the chute has a grade of 1¾ in. to the foot. When dealing with soil or overburden only, the pitch is sufficient to carry the material deposited from the buckets along the chute with the help of a little water. When, however, there is an appreciable proportion of gravel deposited with the earthy matter, the mixture heaps up and requires a push to start it along the chute. The additional water required to gravitate the overburden to the top of the dumped gravel at the stern of the dredge, besides that which comes up in the buckets, is admitted to the chute through a 3-in. pipe, but this pipe does not run full. At date of inspection the discharge was about 10 cu. ft. per minute, while the volume of solid material being moved along the chute was about 30 cu. ft. per minute. Occasionally the 3-in. pipe is blocked by clay, etc., deposited in the chute by the buckets, and at such times the services of a man are required, for a few minutes, to shove the material and start it along toward the tailing dump. Sometimes a whole shift is run without the assistance of this man. It is estimated that this extra work costs about 10s. per week. Between the end of June and the beginning of August 1910, about 1¾ acres had been done, of which half an acre had been neatly leveled off by three of the dredgemen with shovels, working occasionally, and the cost of the work was estimated at about 10s. per week, or, say, £2 per acre. When leveled off, the surface of the re-deposited material is about 12 in. above the adjacent natural surface, and the depth of soil and earthy matter so replaced and leveled off averages from 2½ to 3 ft. In the working face on 5/8/10 the overburden was 4½ ft. thick, consisting of dark-colored soil, sandy loam, and clay, overlying coarse gravelly wash. The water-level in the operating pond was from 1 to 4½ ft. below the surface of the ground. The centre of the lower tumbler-shaft was 3 in. out of the water, and the cut made extended back 6 ft. from the face. The drop from the centre of the top tumbler-shaft to the bed of the soil chute is 3½ ft., of which 2 ft. is occupied by the buckets, leaving 18 in. of a clear fall. Some of the buckets do not empty freely, and most of the contents fall into the well-hole. Occasionally buckets come up with some water, but no dirt. On 5/8/10, the material deposited in the chute was mostly large clods of soil and clay ranging in size from 12 by 6 by 4 in. to 18 by 9 by 5 in.; also some stones were noticed up to 5 by 5 by 4 in. The pitch of 3 in. to the foot at the upper end enables the deposited material to get away readily and reach the tailing dump, after a few short stoppages in the flatter portion of the trough, without much delay. The depth of the material sliding along the chute was usually from 12 to 15 in. The dredge-master stated that with sandy loam soil, the discharge from the 3-in. pipe had to be cut off; such material did not need so much water to move it along as did the mixed material. The advance stripping at this dredge occupied about four hours per day; from the upper tumbler shaft to the deck 19½ ft., and to water-level 22½ ft. The cost of providing and installing the re-soiling appliance on this dredge was less than £100. To obviate the occasional attendance of a man at the head of the chute to give the stuff a start, it is intended to provide an appliance, so arranged as to work automatically from the main shafting. The cost of this arrangement will be moderate. (See illustration, showing soil chute and re-soiled ground.)

Porepunkah Dredge.—A somewhat similar re-soiling appliance to the foregoing has recently been installed on the Porepunkah Dredging Co.'s ground at Porepunkah. The overburden to be dealt with here is of a more friable nature than that at Bonnie Doon, but notwithstanding this, fairly good results were achieved on an area of about one-quarter of an acre which had been re-soiled on 26/10/10 with sufficient material to give an average thickness of 18 in. when leveled off. After that the bedrock rose rapidly, and the dredged material was insufficient, when dumped back into the deeper ground, to show above water-level in the operating pond. Since then the

dredge has been turned round to make for deeper ground, and it is likely that the soil chute will be used with satisfactory results. The overburden is a light sandy soil overlying clayey material and is of poor quality for agricultural purposes.

Good results are being obtained by Hinnomunjie No. 1 plant, working on Livingstone creek, a few miles down stream from Omeo. In this case the ordinary wooden sluice-box is utilized to conduct the soil from the buckets to the dump, but an additional 30-ft. length is brought into use when advance stripping of the overburden is in progress. This admits of the earthy material being deposited well back from the face of the dump, and there retained on top of the gravelly wash, in place of being sluiced back into the operating pond at the stern of the dredge, which would otherwise necessarily occur owing to the large quantity of water required to force the material along the comparatively flat slope of an ordinary sluice-box. The ground being treated in this locality was originally a low-lying marshy area of good black soil. As a result of the early mining operations conducted upstream, more than fifty years ago, the surface of the flat was covered by mining débris to depths of from 3 to 4 ft. Owing to the tenacity of the clayey black soil and to the fact that much of it is matted and held by roots of former vegetation of the swamp, very good results are being obtained in the way of re-soiling, as this black soil brought up from below the old mining débris is deposited in a layer 2 to 4 ft. thick by this plant on the top of its own coarse tailing in large solid lumps, practically unchanged from its virgin state. Certainly this re-soiled land is in a more useful condition at present than it has been during the past fifty years. The surface soil is advance-stripped and conveyed through a main box, where an adjustable extension carries the soil out above 12 ft. beyond the gold-saving boxes. The ground is graded and is covered to average depth of 3 ft. of soil. The area re-soiled is about 30 acres, and oats and potatoes were grown on the dredged ground the first year after treatment. The ground is about 30 ft. deep; the dredge works over 5000 cu. yd. per week. The soil in the face is black, stiff, and swampy, and is stripped separately. About 80% of soil is restored to the dredged ground.

At the Briseis company's No. 2 plant an interesting development has taken place in the matter of advance-stripping top soil and earthy overburden, and depositing it in a useful condition on top of the wash and other coarse material which has passed through the sluice-box. The Briseis company's bucket dredge, known as the Red Bluff No. 2 plant, is provided with a belt-conveyor, and is the first gold-mining dredge constructed in this State on which the use of an effective appliance to deal satisfactorily with overburden has been made a special feature. The plant may be simply described as an ordinary bucket dredge, with sluice-box and belt-conveyor. During the course of an inspection it was ascertained that the buckets, having each a capacity of 4 cu. ft., were traveling at the rate of 12½ per minute. Most of the buckets came up full of earth, but those in which the soil was well pressed did not discharge their contents wholly into the drop-chute, from which the conveyor is fed. In such cases about one-half of the material dropped into the chute, and the rest slipped down the well-hole into the operating pond. The material from the buckets may, by means of the drop-chute, be diverted into the sluice-box or to the conveyor. When overburden is being dealt with, the material from the drop-chute passes to a shaking table operated by springs and eccentric rods, thence on to a traveling belt or conveyor, which may be adjusted to any desired angle. By this appliance it is carried along and dumped well clear of the stern of the dredge, on top of the gravel, previously run through the sluice-box. The rubber belt is 125 ft. long, 2 ft. wide, ½ to ⅝ in. thick, travels over iron rollers, on a steel-framed elevator at the

Re-Soiling Chute, Collegian Dredge.

rate of about 100 ft. per minute. At the date of inspection the buckets were operating on a face of overburden extending from a depth of 8 ft. below water-level, to a height of from 3 to 6 ft. above it, while the depth of soil deposited on the gravel behind the dredge ranged from 3 to 6 ft. Probably about one-third of the alluvium was conveyed by the belt and dumped in a dry and useful condition, one-third went through the well-hole, into the pond, and one-third was scooped up with the auriferous gravel by the buckets, and after passing through the sluice-box was discharged in the form of sludgy water at the stern of the dredge. Revolving tines since have been provided to empty the buckets, and these latter could be altered slightly in shape so as to let the stuff drop out more readily. This is the first plant to install a belt-conveyor to strip and convey the surface soil to the top of the worked gravels. Overburden is deposited behind the dredge in fairly straight rows from 3 to 6 ft. high and 10 ft. apart from ridge to ridge. Area re-soiled on 7/10/09 was 1¼ acres, and requires spreading and grading. About two-thirds of overburden treated

could be transferred from the working face of the cut to the dump at the rear of dredge in a practically dry and uninjured condition.

Briseis No. 1 Plant.—At Briseis No. 1 plant good work is being done in soiling. Overburden is being replaced to depths varying from 4 to 6 ft. on top of the gravelly wash. Grass and clover are growing on those portions of the dredged ground where the re-soiling material has been exposed for two months. The general condition in regard to the character of the ground and the methods adopted for treating same, are somewhat similar to those described in connection with Hinnomunjie No. 1 plant.

Briseis No. 3 Plant.—The Briseis company's plant No. 3, recently constructed at considerable cost, has been provided with a belt-conveyor, and other appliances for re-soiling purposes. Sufficient dredging work has not yet been done with this plant to ascertain exactly what it is capable of doing in the matter of re-soiling worked ground; it promises, however, to be a success.

Another new departure has been taken in regard to re-soiling devices, so far as Victoria is concerned, by the proprietor of the Myrtle Queen dredge working in the Ovens River valley a few miles below Myrtleford. Shortly described, the contrivance consists of an ordinary chute or flume of sheet iron, say, 2 or 2½ ft. wide, with semicircular bottom and vertical sides, and long enough to extend from the upper tumbler shaft to some distance beyond the stern of the pontoon. Inside of this chute and along its whole length, a screw-like mechanical appliance will revolve, by means of which the earthy overburden delivered by the buckets at the upper end of this trough will be shifted forward and deposited on top of the dredged gravelly wash at the stern of the dredge, in almost a dry condition. It is really a screw-conveyor in an open trough, and will shortly be ready for use.

Goldfield Consolidated mill performance in March is given in preliminary figures as, 25,814 tons milled; $1,040,000 gross value; $215,000 total costs. The company expended $195,000 in purchase of additional interests in the Jumbo Extension and Vinegerone. These properties have been operated by the Goldfield Con. M. Co., though owned in part independently. C. S. Herzig, consulting engineer for the Jumbo Extension Co., estimated 73,000 tons of ore blocked out in that property last year. In some quarters this estimate has been criticized as excessive, but a recent examination of the property by G. F. Lewis more than verified Mr. Herzig's figures, Mr. Lewis reporting 87,400 tons, worth $41 per ton. That the Goldfield Consolidated has been studying the ground carefully has been shown by the reports since December.

A power station at Lanekhammer, in Germany, is now transmitting electric current at a pressure of 110,000 volts, which constitutes a record voltage as far as Europe is concerned. The transformer plant, of Siemens-Schuckert type, consists of four three-phase oil-cooled transformers, which step up the generator pressure to the transmission voltage.

The Paracale District

By An Occasional Correspondent

There has been much activity in the Paracale district of the Philippine Islands both in lode mining and placer mining, but the region as a whole has not emerged from the prospecting stage so far as one may be able to judge from the present development and the possibilities in view. Two or three mines, however, are well on the way toward being made into substantial dividend-payers, while results from one dredge in particular that is now operating, together with the returns of some hundreds of test-holes recently put down, go to prove that the

Map of Luzon, Showing Paracale District.

district will finally establish itself as a good producing centre. At the present time the means of communication and its frequency is not what it ought to be to handle the business, both mining and agricultural, that is being developed in the provinces of southeastern Luzon. The service consists of a passenger and freight steamer, making a visit from Manila twice a month. The time of the run from Manila to Paracale is about four days. An overland route to Manila has already been surveyed and it is hoped that a railroad will soon be built. This will give the district daily train service with a run of about one-half a day. Among the placers situated along the Paracale river, those that have been thoroughly tested and their worth proved are the Paracale Gold Dredging Co., the Philippine Exploration Co., the Stanley Gold Dredging Co., and the Para-

cale Extension Gold Dredging Co. Of these the Paracale Gold Dredging Co. and the Stanley are operating, while the others are about to install dredges.

The lower part of the Paracale river runs through large mangrove swamps which necessitate considerable clearing to make the ground dredgable, while farther up, areas of nipa occur, and finally, at the source of the river, there are rice paddies and meadow through which streamlets pass from the

Driving Casing and Lowering Sand-Pump.

surrounding hills. The ground on the upper river has been thoroughly tested and found to average as well as the lower river.

The usual rocks of the district are coarse granites of a gneissic character. Schists, shale, and sandstones are also common to a lesser degree. The region has a great number of quartz veins running in a more or less parallel direction. These veins occur in granite for the most part, but are also found at contacts of granites and the more basic intrusives. The shales and slates in the hills have contributed to the formation of a thick bed of clay in the placer ground. This clay varies in thickness from a few feet to as high as eighteen. It is noticeable that this clay carries gold immediately below the grass roots in the region near the foothills, while farther down the river the gold occurs for the most part close to bedrock, over which is several feet of gravel wash consisting of quartz and eruptive rocks up to 2 inches in size and mixed with the clay. The greatest quantity of gold is found in this layer. As a general rule the number of pebbles present is a sure indication of the richness of the placer. The gravel in the placer has been produced by comparatively recent erosion. The gold is bright, ranges from fine to coarse, and is often spongy in appearance. It is mixed with considerable magnetite and iron pyrite. The presence of sulphides, even in the placers, is to be expected in a region where the rainfall is great, a condition that seems to be quite common in most of the tropical countries. Some thoroughly oxidized portions of lode matter are found on the outskirts of the placers, but these are only local in occurrence. In the lodes the sulphide ores are found immediately below the outcrops in most cases. The bedrock is granite or gneiss and soft enough to drive a pick into it. The depth is variable and ranges from

Raising Casing, Paracale.

12 to 45 feet. The auriferous gravel appears to occur in streaks and follows channels of varying depth and width. It is this condition that makes it advisable to bore more test-holes for a given area than is commonly done in other placer districts. As many as five holes per acre are driven.

Drilling is done by the driving of an ordinary 3-in. wrought-iron pipe casing with smooth joints, and lifting the material out with a flat-valve sand-pump. It is not necessary to use any special means of driving through this tough clay other than the method shown in the photograph. The weight of four men standing on the cross-arms of the casing and rotation of the same by another man is found to be sufficient for depths to 40 ft. The number of feet driven per 10-hour day is about 40, at a cost of 20c. per foot.

Paracale Dredging Ground, Upper River.

Concrete

By Algernon Del Mar

The millwright of today must lay aside his saw and square and take kindly to the shovel and hoe, for concrete is taking the place of much of his heavy timber work. Not only is it more durable than timber, more economical in cost per ton of ore crushed, but it looks better. As a rule, the inside of a stamp-mill is a dirty place, and the structural work crude and unsightly. Compare this with a mill where concrete has been used to its fullest extent. We find now that the mill is neat in appearance, the structure is better architecturally, the mill does better work, the extraction is better, and the mill lasts indefinitely. To obtain the best results from concrete work the following observations and rules may be studied with interest.

The best grades of domestic cement should be used. While some foreign cements are superior to our ordinary brands, even for cementing silex brick in tube-mills, a class of work requiring the best materials, a good brand of domestic cement will answer every requirement. Except when used in large quantities, particularly where the cost of labor is high, it is better to hand-mix all concrete. The mixture of sand and rock, which with cement makes concrete, is often called the agglomerate. Concrete should always be mixed fresh; that which has been mixed over half an hour has had an initial set and should be rejected. The sand should preferably be clean and sharp, although rounded sand-grains or sand that contains from 10 to 15% of dirt has been found not to lessen the strength of the set. The broken rock used should not be larger than a size which will pass a 3-in. ring, and should be well washed before mixing to remove all dust and dirt, so that the cement and sand mortar will adhere to the surfaces.

Cement will not readily take up any more water than is necessary for mixing; the excess will come to the top, and does no harm unless the excess is carried to an extreme, causing a separation of the cement from the agglomerate, thereby weakening the mixture. Wet concrete takes longer to set and eventually becomes harder than when the water is only in sufficient quantity to create adhesion. Concrete of this latter description should be well rammed until water comes to the surface. While setting, concrete should be kept wet, for this retards the setting and, as stated above in respect to wet concrete, it produces a more lasting structure. It is not necessary for any piece of work to be of the same proportional composition throughout, for the richness of a concrete should be proportional to the strains it must bear; for example, the base of a foundation, usually being larger than the top, may be made of a poorer mixture and yet stand the same strain per square inch as the top.

Concrete mixed with fresh water should not be allowed to set when the temperature is below freezing, unless there is a heavy weight upon the structure to keep the mixture in compression, or unless fires are kept burning near the structure, otherwise the concrete may be loose and crumbly. In a recent reference to this subject it is claimed that freezing will not materially injure concrete, for while frozen the setting action ceases to start again when the water thaws. When the temperature is below freezing, the usual plan is to add some chemical to the water that will lower the freezing point. Salt is most commonly used, and when not in excess of 10 per cent of the weight of the water, it makes a stronger structure than fresh water. The salt delays the setting, and lowers the temperature at which the water will freeze. There have been various rules proposed to determine the quantity of salt necessary to prevent freezing. "Add one per cent by weight of salt to the weight of water for each degree F. below freezing", or "one pound of salt to 18 gallons of water for a temperature of 32° F., and an increase of one ounce for each degree lower."

Concrete may be mixed with hot water, and sets more rapidly the hotter the water. A temperature of 150° F. is a safe limit, unless the mass is immediately transferred to the form. It is often necessary in cold weather to heat the rock and sand which may have frozen over night. It is best in this case to thaw the sand before a fire or in a drier, for wet sand and cement mix poorly. In case it is not practicable to use a drier, then the sand should be spread out, the lumps broken up mixed with cement, and hot water used to make a mortar. This will require more work than when dry sand is used, but if time be taken, a good mortar may be made. The rock may be drenched with boiling water.

In structures where the strains are chiefly compressive, the surface of the concrete laid on the previous day should be cleaned and wetted; no other precaution is necessary. If the concrete has set, or it is necessary to lay it intermittently, the surface should be roughened or left with corrugations. Before adding the next batch of concrete, the surface should be cleaned and wetted. Concrete is mixed by volume, not by weight, and all calculations are made upon this basis, although the millwright will generally prefer the bag of cement as his unit and the number of tons of sand and rock. The conversion of volume to tons is simple. The next question is, what should the composition be for a given piece of work. The theory is that, for concrete to be at its highest efficiency, the spaces between the sand should be filled with cement, and those between the rock with cement and sand mortar; therefore the amount of voids or empty spaces between the particles of sand and rock will govern the proportion of the ingredients.

For extensive or accurate work cements are always tested, both chemically and physically, including the percentage of voids in the sand and rock it is proposed to use. The millwright, as a rule, will not bother with these refinements, and will use some arbitrary measure that has proved successful in other similar work. We will consider an average sand and an average rock, and endeavor to work

out our problem, first explaining the mode of mixing the constituents of concrete as found by experience to give the best results. This is a concrete engine-foundation specification for one of our big railroads, and is a fair example of what is considered necessary when mixing concrete.

"About half the sand shall be spread evenly over the bed of the mortar-box, the cement shall be spread evenly over the top of the sand, and finally the remainder of the sand shall be spread on top. The sand and cement shall be thoroughly mixed by turning and re-turning with a shovel. The mixture shall be drawn to one end of the box, water poured in at the other end, and the mixture drawn down to the water with a hoe, a small quantity at a time, and mixed vigorously until there is a stiff mortar. The mixture shall then be leveled off and the required amount of broken stone shall be thoroughly wetted and spread over it. The whole mass shall then be thoroughly mixed by turning and re-turning with shovels into rows, at all times preserving the same thickness of the mass until the mortar completely fills all the interstices of the rock. After transferring to the forms, ram with 20-lb. hammers until water comes to the surface."

The requirements for good concrete are, then, thorough mixture of dry sand and cement, the addition of water to form a mortar, and the thorough mixture of broken stone with this mortar.

To make a concrete where all the voids in both sand and rock are filled, and using the figures for sand and rock as above, the mixture should be 1 cement, 2.5 sand, and 4.6 rock. This is a mixture in which all the spaces between the sand and rock are filled. Experience teaches us that a better result is obtained when the rocks are separated by a layer of mortar and the grains of sand by a layer of cement. This 1:2.5:4.6 mixture does not allow for mistakes in testing or leave allowance for variations in sizes of the material used. By actual tests the best mixture for concrete has been found to be nearer 1:1.5:2. This mixture should bear compressive strains up to 2900 lb. per square inch. When the weight on a foundation is excessive, or subject to sudden changes, the concrete must be at its highest efficiency: therefore a rich mixture such as 1:1.5:2 must be used, but the less the strain on the foundation the poorer the mixture may be, leaving always a safe allowance for the unforeseen, which always happens. Good concrete made with a mixture somewhat richer than that found by calculation will stand a strain of from 2100 to 2800 lb. per square inch. Under tension, concrete will stand from a sixth to a tenth of this, or 200 to 300 lb. A stamp-mill foundation figures out thus:

The base of a mortar for concrete foundation is usually 32 by 60 in., or 1920 sq. in.; the weight of mortar, stamps, dies, ore, etc., about 14,000 lb., or about 7 lb. to the square inch. Two battery-posts 12 by 28 by 21 ft. with cam-shaft, bull-wheel, cams, etc., will weigh about 14,000 lb. The base with sole-plates occupies about 720 sq. in., giving 20 lb. to the square inch. The compressive strain on the foundation of the battery-posts is therefore over twice that on the mortar base. Owing to the vibration caused by the dropping and raising of the stamps, the tension on the foundation bolts will more than equal the compressive strains, therefore the foundation must be at least ten times as strong as if the compressive strain were alone considered. The following table shows the compressive strains that certain mixtures of good concrete will bear:

Cement.	Sand.	Rock.	Pounds per square inch.
1	1½	2	2800 to 2900
1	2	3	2500
1	2	4	2300 to 2400
1	3	4	2100
1	3	5	2000
1	4	6	1700

It would appear from this that at 1:4:6 mixture, if made with good materials, would leave a big factor of safety. The mixture generally used for battery work is from 1:4:4 to 1:3.5:3.5. To bring this up to 1:4:6 and still have a big factor of safety, large rocks up to 8 inches in diameter may be hammered or punched down in the centre of the form as the concrete is built up. This makes a rubble concrete and will not materially lessen the strength of the foundations. Suppose that now we have determined upon a certain mixture, we may want to know the quantity of materials necessary. There is a simple rule which will give approximately the number of barrels of cement in a cubic yard of concrete. Divide 10.5 by the sum of the parts of all the ingredients. For example, in a 1:2:3 mixture there will be 10.5 divided by 6, or 1.7 bbl. per cubic yard of concrete. If the work is of great magnitude, the proportions may be found by actual tests. Knowing the number of cubic yards of concrete and the proportions, and figuring 22 cu. ft. of sand and 20 cu. ft. of broken rock to the ton, the weights of the ingredients may easily be found.

For example, the mortar and battery-post foundations of a 10-stamp mill will contain 20.5 cu. yd. Suppose we use a 1:4:4 mixture; then 10.5 divided by the sum of the ingredients, 9, will give us 1.15 bbl. of cement per cubic yard, or 20.5 by 1.15, or 23.5 bbl. of cement, or 94 bags of portland cement. The cement and sand being as 1 to 4, therefore, as a barrel of loose cement occupies about 4 cu. ft., the sand will occupy 16 cu. ft. per barrel; 16 by 23.5, the number of barrels necessary, will give 376 cu. ft. at 22 cu. ft. per ton, or 17 tons of sand. The rock and sand being in equal proportions, 17 multiplied by 22 divided by 20 will give us 18 tons of rock. As a barrel of cement weighs 400 lb. gross, the amount for this foundation will be 9400 lb., or about 8800 lb. net. These figures are approximate, as we have assumed our data, which, though near an average, may not be correct for some specific example. To make sure, the engineer had better allow an increase of 5% on each item for contingencies; in other words, for the unexpected. A few figures of what may be considered good foundations for water-tight work may be useful. A 4-in. concrete wall will be water-tight under a head of 4 ft.; a 15-in. wall under a head of 20 ft.; while a wall 5 ft. thick will hold water under a head of 100 feet.

Mineral Associations at Porcupine

By Cyril W. Knight

The editorial comment on the article by R. E. Hore in the issue of November 26, 1910, lays undue stress, I think, on the occurrence of carbonate (ankerite or ferro-dolomite) and the green micaceous minerals which are found in association with the gold deposits at Porcupine. It is to be hoped that Porcupine will be of as great economic importance as the mother lode, but emphasizing accidental resemblances, such as those mentioned, can do no good. When a gold camp is discovered there are plenty of boomers ready to compare it with the Rand and other famous fields. Porcupine has already been compared with the greatest goldfields. As a matter of fact, not only the gold deposits in the oldest rocks of Ontario, the Keewatin, are frequently associated with carbonates, but the deposits of iron ore and other minerals are just as frequently similarly associated. At the Helen mine, Michipicoten, there is a large mass of carbonate adjacent to the orebody. There was a stampede to the Larder Lake goldfield, lying about forty miles to the east of Porcupine, in Ontario, in the winter of 1906-7. R. W. Brock made a report on this goldfield for the Provincial Bureau of Mines. In his report, published in the Sixteenth Annual Volume, he thus refers to carbonates and to green minerals such as those found in the Porcupine area: "The most interesting rock from an economic standpoint near Larder lake is a rusty weathered dolomite. About 60% of the rock consists of lime-magnesic-iron carbonate, the remainder of quartz and of a soft green talcose silicate, probably serpentine. * * * This rock, especially where cut by the porphyry pegmatite, is traversed by innumerable stringers of quartz which, in places, are gold-bearing." The green talcose silicate mentioned by Mr. Brock was later studied by Morley Wilson, who, in the summary report of the Geological Survey of Canada in 1909, thus refers to it: "In the neighborhood of Larder lake and north of Lake Opasatika, are local outcrops and bands of a rusty-weathering rock, consisting of ferruginous dolomite or ankerite, with varying quantities of quartz and feldspar. It is always highly pyritic, and in most localities contains a large amount of chrome mica or fuchsite, from which the rock derives its characteristic green color. As a rule the rock is cut in a most complex manner by two or more sets of veinlets consisting of quartz or of quartz and ferruginous dolomite."

On the eastern edge of the Porcupine area, in Night Hawk lake, is Golden island, to which there was a small rush of prospectors in 1906 owing to the discovery of gold there. This, by the way, no doubt resulted in the prospectors searching farther west for gold and led to the discovery of the important deposits in Porcupine. Gold was also found on Lake Abitibi in 1906. The deposits of Lake Abitibi and of Golden island are thus referred to by W. G. Miller in the Bureau of Mines' Report for 1907: "The writer has not visited Night Hawk lake, but among the specimens shown him, from a small island known as Golden island in the northeast part by A. A. Cole, who examined the deposits for the Temiskaming & Northern Ontario railway, it is evident that the deposit there being worked for gold is similar to that described by R. W. Brock on some of the mining claims in the vicinity of Larder lake. This material consists of what appears to be a silicified limestone carrying iron pyrites. Associated with the limestone is the somewhat striking green material which Mr. Brock described as being probably serpentine. * * * The deposits on the shores and islands of the Lower and Upper Abitibi lakes visited by the writer in August last are different from those described by Mr. Brock and Mr. Cole on Larder and Night Hawk lakes, respectively. The chief point of resemblance is that the same green mineral is found in some of the deposits at Abitibi as that in the deposits of the other two lakes."

If the goldfields of the Lake of the Woods region, in western Ontario, which were operated unsuccessfully ten or fifteen years ago, be reviewed, it is apparent that carbonates also occur under similar conditions to those at Porcupine, Larder lake, and other areas alluded to. But the mining man who today has the courage to compare Porcupine with the Lake of the Woods goldfield because of the presence of carbonates would be unpopular in the camps of northern Ontario. It should also be borne in mind that the gold occurrences at Porcupine belong to rocks dating back to a remote period of the earth's history, namely the pre-Cambrian, while the mother lode occurs in rocks of Carboniferous age.

It will thus be seen that the carbonate rock and the green mineral, which have led to the comparison of the Porcupine deposits with those of the mother lode in California, are characteristics not only of Porcupine, but also of Larder lake, Lake Abitibi, Golden island, and some of the properties in the Lake of the Woods area. Hence it would seem that much importance should not be attached to either the carbonate or the green mineral. In fact, the green mineral, whether it is called mariposite or fuchsite, is of such common occurrence in the pre-Cambrian of northeastern Ontario that it is scarcely worth mentioning. The carbonate and other characteristic rocks of Porcupine are described in the notes which accompany the Bureau of Mines map published in August last.

Tripoli is used for a number of purposes, as blotter blocks and scouring bricks, but by far the most important use is for filters. These filters are made in all sizes from the small house filter to filters having a capacity of 400 gal. per hour. The flour is used principally as an abrasive or polisher in the metal-working trades, the finest grade being used as a jewelry polish, while the coarser grades are used as brass or steel polish. The flour is also used to some extent as an ingredient of scouring soaps. No doubt the flour has been used to some extent as an adulterant, as it is nearly pure white, without appreciable grit, and very heavy.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Filter-Pressing Slime

The Editor:

Sir—Mr. J. Chisholm remarked that the patent press used by Mr. Alfred James in Kalgoorlie was invented by him in 1905. In my paper on the above, it was not Alfred James who was mentioned, but Caradoc James, now of Tarkwa, West Africa, although at the time I did not give the initials. C. James was associated with Mr. Chisholm in the experiments of sluicing out presses. I can only say that it is a great pity the invention was not pushed, as it appears to be simple and effective, and quite on a par with the Merrill system.

M. W. VON BERNEWITZ.

Liberty Bell Mill

The Editor:

Sir—In your issue of March 11, W. H. Storms has described the mill of the Liberty Bell G. M. Co. at Telluride. Some important changes have been made at this mill since the time of the visit upon which the description was based. The tube-mill discharge now goes to cones, the underflow of the cones going back to the tube-mill, and the overflow passing to ten Deister tables. These are doing good work, and have materially lowered the mill tailing. The tailing from them goes to Dorr feed-thickeners. The thickened feed goes to the storage-tanks for the Moore filters. As a result of these changes the extraction has been increased without increasing operating costs. The mill is now treating 425 tons per day.

Telluride, March 27. ENGINEER.

Avino Mines of Mexico

The Editor:

Sir—In J. Parke Channing's letter published in the *Mining and Scientific Press* of November 26, 1910, he fails to make matters quite clear with regard to the treatment of Avino ores, by stating that the trouble was due to the presence of tetrahedrite. One would assume from Mr. Channing's statement that the concentration generally was good, with the exception only of silver being carried away contained in the tetrahedrite, thus making an opening for lixiviation, which Mr. Channing claims did excellent work. Was it due, then, to being enabled to secure a capable successor to Mr. Flynn, or because the supply of ore carrying tetrahedrite had failed, that the latter process was shut down? I had been under the impression that lixiviation had not proved a very grand success at Avino, on account of the high silver values in the residues from the process.

Texas Mining Laws

The Editor:

Sir—I beg leave to comment on the proposed mineral law of Texas as outlined in the *Mining and Scientific Press* of March 4. The State of Texas, by inauguration of the policy of separating on its public lands the surface from the mineral rights and reserving the latter as public property, took a step in social equity far in advance of its neighbors. The El Paso Chamber of Commerce now calmly proposes to reverse this sensible policy and, except for oil and gas rights, wishes to give away lode and placer claims for a pittance in the same reckless way pursued, until recently, by the Federal Government. Without mentioning foreign countries, our own experience in the bituminous coalfields, in the Joplin zinc district, in the Mesabi iron range, and at the precious metal mines of Goldfield has shown that the leasing system is as practical for lode and placer deposits as for oil and gas.

The land laws of England were designed to maintain a privileged class, and as copied by this country have created here a class of land monopolists without even the governing responsibilities of their English prototypes. Is not the leasing system of Spanish America much better suited to all the mineral deposits of a democracy than grants in fee simple? At least the progressive English colonies think so, if anything is to be judged from Australia, Canada, and South Africa, where, inheriting like us the aristocratic English land system, recent mineral laws have been framed along the lines of the separation of underground from surface rights and of society's inalienable right to its mineral property as embodied in royalty payments from mining lessees. The Transvaal collects 60% of the profits of the Premier diamond mine, and Canada shares liberally in the gains of many Cobalt mining companies.

Should not Texas be sustained by mining producers in her efforts to retain for the community by leasing, the net value of its minerals? Should we not as American citizens begin to call a halt on mineral monopolists and speculators who have tied up most of the coal and iron deposits of the East, and of precious metal claims of the West with the object of holding them indefinitely until paid their price to let go? Why not give mental and manual productive labor the lion's share of industrial rewards which is now going to such types of social highwaymen as forestallers and gamblers in land values?

The suggested Texas policy may prove financially advantageous temporarily for some of its purposes, but is it not about time that land laws be made with some other thoughts than those plausible but deceptive slogans, 'Develop the country,' 'There is no god but Bigness,' etc.? Is not the working as compared with the gambling miner better off in a country whose unused mineral resources are always open to his enterprise than in one where they have been patented and are held permanently at little or no expense by those who either can not or will not develop them? R. B. BRINSMADE.

Morgantown, Virginia, April 1.

Revolutions and Mining

The Editor:

Sir—I read with interest T. Lane Carter's article on 'Revolutions and Mining' in your issue of January 7. Had Mr. Carter used the expression 'eastern Nicaragua' instead of plain 'Nicaragua' throughout, his contribution would have been an accurate picture of local conditions. By ignoring western Nicaragua, and by imagining Bluefields to be to Nicaragua what Paris is to France, he has been led into such inaccuracy as to impair considerably the value of his essay.

Eastern and western Nicaragua are to all intents and purposes distinct countries. They are more difficult of access, the one from the other, than New York and California; and have different currency, different tariffs, different systems of government, different aims, and different modes of thought. The Atlantic littoral has always been a hot-bed of revolution. As such it was treated by the central government very much as the English long treated Ireland, and with about as much reason. When I lived there the economic and financial control of the country was being slowly secured by a notorious foreign trust, whose name is anathema to all patriotic Central Americans, regardless of country or party. Squeezed between the Trust on one side and Managua on the other, everyone, both native and foreigner, was 'agin the government.'

On the other hand, in western Nicaragua—the dog in contradistinction to the eastern Nicaraguan tail—Zelaya was popular in the extreme. He ruled justly, wisely, and humanely. In ten years there had been but one political execution. I was a resident of that part of the country when the late revolution broke out, and was in touch with the leading British, German, and American business people there. All were in favor of Zelaya, and, to emendate Mr. Carter, "no one doubted for a moment that Estrada and his crowd would be thrown out." Estrada would never have had a chance had not a foreign power, misled by its diplomatic representatives and egged on by trusts and concessions with axes to grind, thrown its weight—in the shape of money, arms, and 'deserters'—into the wrong pan of the balance.

Zelaya was probably the best, certainly the ablest, ruler Nicaragua ever had. The stories of his cruelties and 'infamous private life' are ludicrous to those who know the man. Estrada I have not the pleasure of knowing. Those best informed consider him a tool in the hands of Chamorro and the Conservatives. To my mind, the future outlook of Nicaragua is anything but peaceful, as I don't think the people of western Nicaragua will ever submit quietly to a Conservative régime. About three years ago a couple of young Americans down in Nicaragua bought a promising looking mine 'on spec.' They paid two or three thousand dollars deposit—all they had. Pressed for payment, and without resources, they applied to Zelaya for aid. He advanced them $30,000. The other day that mine was sold for ten times that sum; the young men netting some $100,000 apiece on an investment of $1000. Many another foreigner could tell of similar kindnesses if he would; but when a man is down—hit him good and hard. Mr. Carter opines South African metallurgists think they know it all. Are they the only ones?

HUXLEY ST. JOHN BROOKS.

Benguet, P. I., February 17.

Steam-Shovel Mining

The Editor:

Sir—I must take issue with you on your editorial of March 4, in which you say that mining engineers have too long allowed civil engineers the exclusive use of steam-shovels. The present powerful shovel has been developd entirely by the mining profession, and practically upon the Mesabi range in Minnesota. The first steam-shovel that, to my knowledge, was ever used upon iron ore was put in commission in the spring of 1887 by Joseph Sellwood to load the accumulated winter's stock pile at the Colby mine, near Bessemer, Michigan. The suggestion came from Nicholas J. Cavanaugh, then an employee of the mine, who is now a resident of Vancouver, British Columbia. Mr. Sellwood procured from the Milwaukee, Lake Shore & Western railway (now a part of the Chicago & Northwestern system) a small shovel which was designed to dig gravel ballast. The whole thing was done very quietly, and about 11 o'clock in the morning the news was spread over the town of Bessemer that ore was being loaded into the 20-ton cars at the rate of a car in three minutes. Few people would credit this, and nearly the whole of the population climbed to the top of the hill to see this wonderful performance. This undoubtedly was the forerunner of steam-shovel open-pit mining. Next, the Lake Superior Mining Company, at Ishpeming, Michigan, got a steam-shovel to load its hard-ore stock-pile, and the following year nearly every mine of importance was provided with a steam-shovel.

About 1890 the Mesabi range was coming into prominence, and John Jones, of Iron Mountain, had started to strip the Biwabik mine, and used shovels at his two pits. Gradually the shovels which were used for stripping came into use for mining the ore, and in the early days it was found necessary to have at least two shovels, in order to keep one going. It was impossible to design a shovel on the drafting-board, so makers gradually increased the size of this part and that when they broke, until data were established from hard experience. It is unnecessary to show the evolution of the mammoth steam-shovel, such as is used in the Mesabi range pits and in the Culebra cut of the Panama Canal from the little sand-shovel which Joseph Sellwood used in 1887 to load the Colby stock-pile. On the Mesabi this development was made, however, and the engineers of the Panama Canal can thank the mining engineers of Lake Superior for the present magnificent machines which dig into almost solid rock as readily as the old shovel went into a sand pit.

J. PARKE CHANNING.

Miami, Arizona, March 14.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Rutile (titaninm oxide) is used in making ferrotitanium, which is added to the steel for steel rails, the use for this purpose having grown considerably of late. It is also used in making electrodes for are-lamps.

Linseed oil is commonly adulterated. The easiest way to test this is to shake it in a flask with eqnal parts of nitric acid and then allow it to stand for 20 minutes. If the oil is pure, the upper layer will be straw colored, but if impure it will be dark brown.

Phosphorus occurs in two forms, one red and the other white. The former is harmless, the latter is poisonous and inflammable. Its use in matchmaking is attended with great danger to the workmen, and it is probable that its use will be prohibited by law.

A recent method for applying metallic coatings, consists in spraying the molten metal by the pressure of some inert gas through a nozzle in a fine spray against the surface to be coated. In this way much larger pieces can be coated than was possible by former methods.

The manufacture of steel in electric furnaces depends on several factors, but the most important is the cost of electric power. A recent plant has contracted for its supply at $6.70 per horse-power year; where the cost of electric power is not low the making of steel by this method is impracticable. The greatest progress has been made in Norway.

Asbestos board is a good covering for laboratory table tops if it is not necessary to wash them off at intervals, but it has the disadvantage that small particles of fibre detach themselves after the surface becomes worn, and these are likely to get into the material being analyzed. A good surface, for a makeshift, can be obtained by giving the board a coat of varnish. The coating must be very thin; otherwise hot objects will stick to it.

Mixing rich ore with that which is poor does not make the low-grade ore any better or any more profitable. On the other hand, it robs the rich ore of a portion of the profit that might have been made on it. It is not an uncommon thing, however, to mill ore taken out in the course of development which cannot be mined and milled at a profit, but which will yield more than the cost of milling. In such cases it is good business to mill all such ore.

Prospect-shafts should, unless there is strong reason to the contrary, be sunk at the points along the lode where ore has been found. Cross-cut tunnels, vertical shafts in the hanging, and inclined shafts in the foot, are proper means of mining after the form, character, and size of the ore-shoots have been determined. The first essential to a successful mine, however, is a good ore-shoot, and the best way to determine its presence or absence is to follow the ore.

In testing placer ground by panning, a balance is not always available. Colors may be preserved without danger of loss or confusion by making a small ball of clay and dabbing the dried pannings in it, rolling them in a little ball and drying by the fire. Before it is dry, a mark may be scratched on the outside to identify the sample. When convenient, the ball may be broken up in water and the gold panned off and weighed. This method is often a great convenience where samples have to be transported on horseback.

Gravel and sand, occurring on the public land, suitable for mixing in concrete, but having no property or characteristic giving them special value, and deriving their chief value from proximity to town, do not render the land in which they are found mineral in character within the meaning of the mining laws, according to Land Office Decision in the case of Zimmerman *v.* Bunsen. The Supreme Court of Oregon, on the contrary, has held that building sand is a mineral, and hence that land containing it is subject to placer location.

A location certificate should contain the names of all the persons interested in the claim. When the locator of a claim places the name of another person on the location certificate, the person named at once acquires a legal interest and title in the property located, and the locator can not thereafter deprive the person named in his certificate by removal of the name, even though they may have become enemies since the name was first placed on the location ertificate. In other words, you can take another person in with you in the location of a mining claim, but you can not, on second thought, for any reason deprive that person of his rights in the claim.

Slag-wool, or silicate-cotton, as it is sometimes called, owing to its resemblance to cotton-wool, is made from blast-furnace slag. The process of production is, briefly, as follows: A jet of steam is made to strike upon the stream of molten slag as it falls from the runner into the car. This steam-jet scatters the molten slag into drops, and as each drop leaves the stream it carries with it a fine thread or tail. The chilled drop, being heavy, falls to the ground, while the fine woolly fibre is sucked into a large tube and discharged into a chamber. This chamber is of large size, and is covered with fine netting. The steam and air carry the woolly particles all over the chamber, the finer into recesses in the chamber, and the heavier into the body of the chamber. After each blowing it is taken up with forks and put into bags or barrels for sale. Slag-wool, or silicate-cotton, is chiefly used for covering steam-boilers and pipes. Its perfect incombustibility, combined with its non-conducting and indestructible properties, gives this material many advantages for this class of work.

THE OLD DOMINION.

The Old Dominion Copper Mining & Smelting Co., identified with the Phelps, Dodge & Co. interests, which operates the Old Dominion mines, concentrator, and smelter at Globe, Arizona, produced, in round numbers, 28,000,000 lb. of copper during 1910, at the cost of about 10¼c. per pound, the average price at which the metal was marketed having been close to 12¾c. per pound.

DIVIDENDS

The Kendall Gold M. Co., Kendall, Montana, paid dividend No. 76, of $10,000, this month, making a total to date of $1,355,000. The property is in Judith basin, and is controlled by Finch & Campbell of Spokane.

The Hecla M. Co., operating the Hecla mine at Burke, Idaho, this month paid dividend No. 93, of $10,000, making $40,000 thus far in 1911, and a total to date of $2,150,000.

The Hedley Gold M. Co., a New York company, operating the Nickel Plate mine and mill at Hedley, British Columbia, paid a dividend of $60,000 on March 31, making a total amount of dividends to date of $263,986.

RECOVERY OF METALS FROM FLUE-DUST

The Copper Queen Consolidated M. Co., which is increasing and improving its facilities for treating the fine ore and flue-dust at its Douglas, Arizona, reduction works, recovered 17,716,692 lb. of copper, 185,541 oz. silver, and 2240 oz. gold from flue-dust during 1910. The dust treated equaled 7.44% of the original charge. The new equipment being constructed, which is to be ready for service by the end of this year, consists of two reverberatory furnaces, and six calcining roasters of the McDougall pattern; additional flue-dust chambers and a new converter flue, connecting the eight stands of converters with the dust-chambers, are already completed.

MARCH PRODUCTION OF BUTTE MINES.

The copper production for March by the Butte mines aggregated about 21,552,060 lb. The output of ore and the production of copper for the month were as follows:

Companies.	Tons of ore.	Pounds copper.
Anaconda	108,500	6,618,500
Butte & Boston	13,020	807,240
Parrot	9,610	605,430
Washoe	9,300	567,300
Trenton	12,400	719,200
Original	20,150	1,249,300
North Butte	26,350	1,607,350
Butte Coalition	27,900	1,897,200
Tuolumne	3,100	279,000
Boston & Montana	96,410	6,170,240
East Butte	11,780	1,001,300
Totals	338,520	21,522,060

THE COPPER PRODUCERS ASSOCIATION

The report of the Copper Producers Association for March shows a production for that month of 20,000,000 lb. in excess of that for February, which marks an increase in copper stocks on hand of 5,370,164 lb. over those of the previous month, when the gain over the January supply was 14,200,000 lb. The total consumption, domestic and foreign, for March amounted to nearly 30,000,000 lb. in excess of the February consumption. Stocks of marketable copper on hand at all points in the United States on March 1 are given at 150,637,770 lb.; and the production of marketable copper during March in the United States from all domestic and foreign sources amounted to 130,592,080 lb. The March deliveries of marketable copper for domestic consumption amounted to 66,080,789 lb.; those for export aggregated 59,081,127 lb., making total deliveries of 125,161,916 lb. Stocks of marketable copper at all points in the United States on April 1 are reported at 102,007,934 lb. The March output of copper is 3,000,000 lb. in excess of that of any previous month of which a record is given.

MINES OF WESTERN AUSTRALIA

The names of the principal producing mines of Western Australia are given in the following table, with figures showing the tonnage of ore produced in 1910, the value of the product, and the profit for the year:

Name.	Tonnage.	Yield.	Profit.
Associated	3,739	$ 25,000	.....
Associated Northern Blocks	2,453	23,000	$ 10,000
Burbank's Main Lode	1,657	22,000	.....
Chaffers	3,740	24,000	270
Golden Horse-Shoe	22,418	143,000	9,500
Golden Ridge	2,705	31,000	15,000
Great Boulder Perseverance	20,003	129,000	32,500
Great Boulder Proprietary	16,558	242,000	117,000
Great Fingall	10,185	76,000	13,000
Hainault	4,651	33,400	3,700
Ivanhoe	19,511	189,000	90,000
Kalgurli	8,450	105,000	53,000
Lake View Consols	9,440	8,000	2,000
Lake View & Star	13,316	82,000	3,400
Oroya Exploration	21,832	23,500	10,500
Oroya Black Range	4,350	43,500	11,000
Oroya Links	7,515	24,500	3,000
Sons of Gwalia	13,501	118,000	46,000
Sons of Gwalia South	2,480	23,000	8,500
South Kalgurli	9,220	60,500	12,000

The three properties from the output of which dividends were paid within the year were as follows: Associated Northern Blocks, $43,500; Ivanhoe, $250,000; Kalgurli, $185,000.

THE MT. ANDREW MINE

The mine of the Mt. Andrew Iron & Copper Mining Co., situated on the south side of Kasaan peninsula, Prince of Wales island, Alaska, is reported by our Ketchikan correspondent as having been bonded to the United States Smelting, Refining & Mining Co. The importance of this information is due to the fact that the Mt. Andrew mine contains deposits of high-grade iron and copper ore of considerable magnitude, as has been demonstrated by the operations thereon during the last three years. Approximately 80,000 tons of ore has been shipped from the property since it was first opened, and this product found a ready market at the smelters of the Northwest. According to information given out by the owners last summer, shipments of ore in 2500-ton cargoes sampled 40 to 50% iron, 4½ to 6% copper, 3½% lime, and 8 to 10% silica; there is also a gold and silver content, those metals being worth $1 to $1.25 per ton. This is a clean sulphide ore, and occurs below a gossan capping. The orebody strikes along a contact of limestone and syenite, in irregular deposits. A working level was driven from the side of the mountain, by which the orebody was opened 100 ft. below the surface; drifts were extended from this level in opposite directions and the ore was blocked out. Raises were made at various places to the surface, connecting with open pits in which the ore near the surface was blasted and passed through chutes to the main level. Later work has extended the workings considerably below the adit-level. The width of the deposit, as shown by this development, is approximately 150 ft. The ore is transported to the ore-bunkers on Kasaan bay over a 3060-ft. aerial tramway. A marked feature of Mt. Andrew ore is the uniformity of its iron and copper content. A force of over 100 men was employed at the property last season. The principal owners are Samuel Lichtenstadter and M. D. Haynes of Seattle. The property a few years ago was under lease to the Britannia Smelting Co. of British Columbia. It is understood that the mine is to be examined and sampled in the interest of those who hold the option.

Special Correspondence

GOLDFIELD, NEVADA

Record Bullion Shipment. —Deep Level Development.— Shaft-Sinking at the Florence.—A Large Orebody.—Jumbo Extension.

Another record shipment of gold bullion, estimated to be worth $480,000, was consigned to the Selby company by the Consolidated Mines company a few days ago. The bullion as now shipped is about 900 fine, a great improvement having been effected by the new refinery, which is said to make a saving of at least $5000 monthly in improved recovery and reduction of transportation charges. New processes for the treatment of concentrate and other mill products, which have been perfected by J. W. Hutchinson, superintendent of the 100-stamp mill, enable the company to treat all these products locally, eliminating the former heavy expense of shipping the concentrate to the smelters. In the final report of J. F. Thorn, the company's general superintendent, of operations in February, the recovery and profits are shown to be considerably in excess of the preliminary estimates, issued early last month. From the total production of 23,675 tons the gross recovery was $973,730 and net profits amounted to $719,325. The average value of the ore was $41.13, with an average recovery from milling of $38.59 per ton or 93.84%. Total operating costs were $8.31 per ton, a slight increase over the costs of the preceding month, due to the higher grade of ore. Development work for the month aggregated 4220 ft. No new discoveries of note are reported, but known orebodies have been extended at many points, and special mention is made of operations in the territory at the south of the Combination No. 1 claim, in and near the old Reilly lease ore-shoot and the continued opening of the Red Top vein from the Laguna workings on the 600-ft. level, where a large tonnage of $15 to $20 ore is being blocked. It is now predicted by the management that the March output will be at least equal to that of February and possibly greater. On the deeper levels, from the Clermont shaft on the 1000 and from the Grizzly Bear shaft at 1170 ft. development continues with satisfactory results and the drifts from the latter shaft are nearing the point where the downward extension of the great Clermont ore-shoot, exposed on the 750, 900, and 1000-ft. levels, should be penetrated. Two mining engineers, Albert Burch, of San Francisco, acting for the Consolidated Mines Co., and Walter E. Wiley, of Los Angeles, representing the Jumbo Extension Mining Co., have just completed the work of sampling, measuring, and appraising the orebodies of the Vinegerone Fraction which, by the terms of an agreement recently entered into between J. H. Mackenzie, managing director of the Consolidated, and Thomas G. Lockhart, president of the Jumbo Extension, will become the sole property of the Consolidated company by the purchase by the latter of the Jumbo Extension's one-half interest in the ore contained in the territory. Under the agreement the Consolidated will deduct a sum equal to $9 per ton as a total charge for mining, milling, and metallurgical losses. The Vinegerone is a narrow fraction lying between the side lines of the Red Top and Miss Jessie claims and contains one of the strongest points in the Red Top vein, which dips east through the fraction, and has been developed on its strike within the claim for 900 ft. The ore is said to be of excellent grade and of an unusual degree of uniformity in character throughout and will afford a large tonnage for immediate treatment at the hands of the Consolidated company, as it is practically blocked out by workings of the Red Top on and above the 360-ft. level and proved for a considerably greater depth by winzes. A 65-ft. raise from the 350-ft. level is said to have yielded $25,000 net and for a long distance the stopes of the Red Top mine have opened the ore along the vertical side-line on the west of the ore. It is said that there will be little delay in reaching a final agreement upon the submission of the appraisers' report and that the transaction will place a handsome cash balance in the treasury of the Jumbo Extension company.

At the Florence Goldfield mine good progress has been made in sinking the main shaft, which has passed the 700-ft. point, near which a station is being cut. It has not been possible to cut stations at exact intervals of 100 ft., owing to the condition of the ground which, in places in this mine, is known locally as 'gumbo,' and in driving frequently requires continuous piling for considerable distances and must be caught up at once by timbers to prevent its slipping and sloughing. Drifts have been started on the 670-ft. level to the south and east to reach the lower extension of ore-shoots that have been opened in the old lease workings on various levels down to the 500, and the workings at this depth will be extended far to the south to a point through and beyond the large andesite dike which, apparently from fault action, has been turned nearly at right angles with the main veins of the Florence and has been supposed to cut off the ore just south of the Florence hill and the highly productive Little-Florence and Rogers leases. A similar dike appears between the main Florence and Engineers' veins, east of the Florence shaft, and when the earlier lease workings encountered this dike the work was abandoned at this point and directed elsewhere. Later a cross-cut was driven through the dike, some 20 ft., and on the other side were found the bonanza orebodies of the Engineers' lease which produced high-grade ore to the amount of several millions within a short period. During the past two months the Florence has been developing a large body of excellent ore at the northern extremity of the Florence claim, in territory formerly included in the famous Reilly lease and adjoining the ground from which the Consolidated has been mining high-grade ore recently. This vein for some distance has its apex outside and west of the Florence boundary, but by the terms of an early agreement between the Florence and Consolidated companies a small fraction, less than 100 ft. wide and 300 ft. long, was equally divided between the two, giving the Florence a part of the vein. A peculiarity of this vein is that, after dipping to the west for less than 100 ft., it buckles back and dips east toward the centre of the Florence. This explains the failure of several lessees who have worked to a depth of over 600 ft. on the Combination No. 2 in quest of this vein. As a result of opening this vein on the 350-ft. level, nearly 100 ft. below the old lease workings, the company is recovering a good quantity of ore of better grade than that handled for many months past and mill heads have advanced correspondingly. At several other points in the mine high-grade ore is being broken and the outlook is better than for more than a year past.

Jumbo Extension has been a centre of interest, owing partly to the negotiations for the sale to Consolidated of its one-half interest in the Vinegerone Fraction and to the fact that ore of excellent grade is being shipped from the Goldfield Annex Co. lease on the Polverde claim, adjoining the Clermont on the east. This is the only work now in progress on this company's claims, but T. G. Lockhart, the president, announces that development work may be started before long, as the company has the privilege of operating from the Annex shaft. This shaft is 1060 ft. deep, the second deepest in the district. In sinking the shaft some ore was exposed at about 700 ft. and last year the lessees shipped some ore from drifts on the 800-ft. level, but the ore apparently became exhausted at this point after sinking to the present depth and failing to find the ore on the 1000-ft. level, work was resumed on the 800, with the result that the ore-shoot was found and several shipments have been sent to the sampler. Within the past week another ore-shoot of good proportions and yielding better assays than any yet found, has been exposed on the 800-ft. level to the south, the 800 drift being north of the shaft. Preparations have been made to increase the volume of shipments and the prospects for future operations are regarded as exceptionally bright. The Jumbo Extension company will probably begin work on the 1000-ft. level after the present southeast drift has progressed another 100 ft. to the boundary of the leased territory.

SPOKANE, WASHINGTON

Review of Mining in the Northwest. — Operations for 1910 Satisfactory.—Record of Production in British Columbia. — Coal Mines. —The Coeur d'Alene.

Reviewing the mining situation in the Northwest, L. K. Armstrong, secretary of the Northwest Conservation Association, says that a year ago the vitality of the industry in the Northwest was about at its lowest ebb. A period of intense activity, due to high metal prices, had been followed by the beginning of a more sane system of development and metallurgical economies not heretofore practised, with the result that the industry appeared from the outside to afford little profit in the face of the low prices of the metals, especially copper, which remained at about one-half the price it had commanded three years previously. Reports to the effect that elsewhere copper was being produced and marketed at a cost of about 7c. per pound, with large ore reserves to draw from, added to the disquieting conditions. The other side of the picture, however, is not quite so discouraging. Mining corporations and individuals, having large investments, had realized

British Columbia.

that the industry would not long continue under high pressure, and began the introduction of newer and better methods, so that by the advent of 1910 it was discovered that these plans were being carried out with success. Meanwhile development plans had been maturing, projects were undertaken which resulted in greatly increasing the ore tonnage in some of the mines. The statement of one operator that the older camps were excellent fields in which to prospect has been emphasized in the discovery and development of large orebodies in mines hitherto little known. Including the great copper camp of Butte, dividends paid by companies operating in Montana, Idaho, Washington, and southern British Columbia, exclusive of coal companies, aggregated $7,266,332. These dividends were paid by companies operating gold, lead-silver, and copper mines, and representing about 6% of the total value of the production. So the year 1910 was one of the most satisfactory in the history of mining in the Northwest.

In the British Columbia Crows Nest Pass coalfields three companies, the Crows Nest Pass Coal Co., Corbin Coal & Coke, and Hosmer Mines Ltd., mined about 25% more coal than the district produced the previous year. On the Alberta side, in which Spokane capital is largely interested, the production was equally satisfactory. Excepting the St. Eugene, and a few others less important, the argentiferous lead mines of both East and West Kootenai had an era of renewed activity, the one serious drawback being that the Kaslo & Slocan railway, connecting several of the important mines with the navigable waters of Kootenai lake, was completely wiped off the map for several miles by the forest fires which devastated the country last summer. A remedy for this disaster, however, is to be found in the early completion of the Canadian Pacific railway to the mines. Cutting the ore on the 1050-ft. level of the Rambler-Cariboo, the discovery of vast deposits of silver-lead ore in the Standard mine and the continued discoveries of zinc ore in the Lucky Jim, assure the Slocan a period of great activity. The mines about Ainsworth, as a result of the advent of several Spokane men in the field, will resume more extensive development. Nelson is properly the centre for the Toad Mountain, Forty-nine Creek, Sheep Creek, Ymir, Salmo, and Erie districts, where operation, reduction, and shipments have been kept up. Sheep creek has a high record for the amount of gold bullion shipped during the past year, the Nugget and Queen mines alone having produced over $200,000. The Yankee Girl at Ymir shipped nearly 5000 tons in course of development.

West fork of Kettle river, Princeton, and surrounding territory began to attract capital last year, the former with the assurance of all-rail connections with the outside world, and the latter because of that fact and the consequent coal shipments and metal mines developments. As a coal-producing State, Washington stands at the head of the list on the Pacific Coast. Out of a production of between four and a half and five million tons, the mines of Kittitas county produced considerably more than half. The total value of the entire production at $2.25 per ton at the mine would amount to more than $10,000,000. Building of railroads into Okanogan county has already stimulated mining, several important projects having been started or are now being projected, among which is a smelter near Oroville. At Chesaw, men friendly to the Granby company have located a number of claims upon which a large amount of money is to be expended in development. Nespelem, at the southeastern border of the county, has some remarkable deposits of copper, gold, and lead-silver ore now being developed. The First Thought mine, at Orient, soon may be provided with a cyanide plant for treating its ores. At the Napoleon mine, below Orient, a cyanide plant has been installed to treat the carbonate ores of that mine. It will take several years to mine and treat these surface ores, from which several million dollars will be extracted. Shipping operations around Northport were confined to a small tonnage of lead ore, the production of the Last Chance mine, owned by the Jupiter Lead Co. The only shipper at Chewelah was the United Copper.

Loon Lake, Germania, and Deer Park, all in Stevens county, Washington, have been active in exploiting the tungsten deposits which promise to make Washington famous. The ores of the Stevens county mines are of exceptionally high grade and can enter any market in the world in competition with other raw ores. However, it is the intention of at least one company to build a metallurgical plant near the mines, and market only the refined products. Built into the heart of the Metaline district, the I. & W. N. railway provides an outlet for the ores of that region. Several mines will revenue shipments this year under the new conditions, having an all-rail connection with smelters at Tacoma and elsewhere. But the premier mine of Bonner county, Idaho, is the Idaho-Continental, which now has an estimated lead-silver tonnage blocked out valued at about $4,000,000. Developed to the 500-ft. level, this mine has been opened laterally for several hundred feet, with the limits of the ore-shoots as yet undetermined. A railroad is to be constructed to the mine by the Great Northern company, and a 500-ton concentrating plant will be erected this year to treat the lower-grade ore. Around Lake Pend Oreille development is about normal except near Clark's Fork, where the Lawrence mine has a large body of silver-lead ore. Some tests have been made at the Webber mine in the hope of effecting a satisfactory saving by cyaniding the silver ores. These

tests are still being carried on. The Panhandle smelter remains idle. In verification of the statement made by Stanly A. Easton, manager of the Bunker Hill & Sullivan mine, to the effect that the older camps offer a splendid chance to prospect, the Jack Waite, Marsh, Caledonia, and Stewart, in the Coeur d'Alene, are now classed as new mines, which are upon a shipping basis. The Ajax is in readiness to take its place beside them. Operations at the deep levels of the Morning have disclosed the wonderful possibilities of that mine. Hecla also increases in value with depth. Hercules, Federal, Bunker Hill & Sullivan each contributed to the increased production, the last named having in contemplation the building of another 500-ton unit to its mill, bringing the capacity of the plant up to 2000 tons per day. Better ore-dressing methods are steadily being introduced.

COCHISE COUNTY, ARIZONA

Interesting Notes on Ore Occurrence and Mine Development in Johnson Camp.—A Gold Mine.

The camp of Johnson, Arizona, is more active than it has been for some time, and the results are good. The Arizona United company two years ago erected and started a small but efficient smelter, which so far as good work is concerned was all right; but sulphide ore had not been developed, and iron deposits close at hand were made use of, thus necessitating the purchase and shipping in of these materials, and the plant closed down indefinitely. This put a damper on the camp, and operations ceased, except those of the Black Prince Copper Co., a Denver corporation, and the Peacock Copper Co., an El Paso concern, each of which has worked constantly, the former on a large scale. Johnstown, Pennsylvania, people have taken over the Arizona United and are using a churn-drill, and it is believed that the property will make good. The Peacock Copper Co. owns a large acreage of ground on the southeasterly edge of the camp, in which there are many croppings of copper-silver ore. They have a 125-ft. inclined shaft on one of the faults, most of this depth in ore; but a new incline has been started and is now down about 75 ft. This work is in limestone, and is being directed by Herbert S. Wein. The opening follows the vein all the way on a clearly-defined contact. For about 45 ft. the work was in hard dolomite; but a change occurred, and the drills penetrated better ground. At 60 ft. there was ore in small quantity, but of good grade, and the body is increasing with depth. The ore on the dump consists of bornite, azurite, and malachite. As this is more in the nature of exploratory work, no equipment has been constructed. But Mr. Wein has a wooden headframe, the cable is attached to a wagon a short distance up the hill, and instead of turning on the steam he calls 'geddap,' and the bucket begins to rise; in this way at practically no expense the ore and waste are brought up. The shaft starts at the bottom of the arroyo and attains depth rapidly; and water-level will be reached soon. The indications are good here, and the work is being well done. The incline will be equipped with a hoist when 100 ft. is reached.

About three miles from Cochise are the 12 claims of the Cochise Gold Mining & Milling Co., yielding gold ore. Seth Merrill is in charge of the work. The properties have been prospected by about 800 ft. of work. There appears to be a porphyry dike, 40 to 140 ft. in width, in which the gold occurs, assaying about $3.50 per ton, and it appears to be free-milling. Both walls are well defined. The adits, 45 and 62 ft., respectively, have been driven to the foot-wall, all the way in ore. In driving a drift 35 ft. on the strike of the lode the ore sampled about $4 per ton. The porphyry crosses a deep arroyo, making an ideal site for a mill. Abundant water is to be had two miles distant, but as it is anticipated that better ore will be found at water-level, a new shaft, now down 40 ft., is being sunk with the intention of reaching the water. 'Specimen ore' is to be found at almost any point on the property, and one face in an open cut is heavily impregnated with gold, easily seen without a glass.

JOHANNESBURG, TRANSVAAL

The 1910 Output of the Rand Mines.—Interesting Data on Costs and Profits.—Testing Drills. — Mill Practice. — Centralizing Operations at Crown Mines.

The annual meeting of the Transvaal Chamber of Mines was held here on February 23. The retiring president, T. G. Hamilton, who manages the affairs of the Consolidated Mines Selection Co., in South Africa, made a noteworthy address on the progress of the industry during his year of office, and he also dealt at length with the outlook for Transvaal mining in the immediate future. Mr. Hamilton prefaced his address by stating that the mining industry had steadily continued to advance its scope, and that the annual gold output of the Witwatersrand had for the first time exceeded a value of £30,000,000, as the result of last year's work. To be precise, the gold output of the Transvaal amounted to £32,001,735, the contribution of the Rand being £30,703,912. The output figures for 1909 were £30,925,388 and £29,900,359, respectively. These figures assume additional importance when considered in relation to the gold production of the world. In 1895 the Transvaal's output was 21%, in 1905 it was 27%, and for 1910 it is estimated that the Colony produced more than 34% of the total. Analyzing the output of the Witwatersrand, it is ascertained that £19,000,000, or 62% of the output went in working costs. Dividends paid amounted to £8,876,085, or 29%, and the balance was absorbed in profits tax, interest on loans, capital expenditure, etc. For 1909 the corresponding figures were 60% working expenditure, 31% dividends, and 9% miscellaneous. Working costs 'for incidental reasons' increased from 17s. 1d. per ton in 1909 to 17s. 7d. per ton in 1910. To a large degree the increase is accounted for by pursuance of a policy in which low-working costs have not been set in the forefront of the managerial program to the extent that has obtained in other years. Working profits, it may be noted, decreased from 11s. 6d. per ton in 1909 to 10s. 6d. per ton in 1910, and the aggregate profit was, therefore, £11,216,105, as against £11,794,376 in 1909, despite the crushing of an additional 888,782 tons of ore. The stamp duty for the last year was 7.19 tons per diem. The number of Europeans employed on the gold mines during December last was 25,376, as compared with 23,126 in December 1909.

Among the many important matters dealt with in the Chamber's report, and discussed by Mr. Hamilton at the meeting, particular reference must be made to the increasing use of rock-drills in the mines of the Witwatersrand. As a result of the recent stope-drilling competition there has been a decided improvement in the types of small drills that find a market on the Witwatersrand for stoping purposes. Mr. Hamilton drew special attention to the deduction arrived at by the committee superintending the investigation, which was to the effect "that under suitable conditions, both as regards mining and efficient working, it is possible to break ground as cheaply and keep stopes as narrow as required with small machines as with hammer-boys." In addition to the data gained in the drill competition important experimental work has been in progress at the Robinson Deep mine under the auspices of the Mines Trials Committee, and has as its object the determination of the best quality of steel for drilling work and the most suitable forges and devices for sharpening drills. Valuable information has been gained from the experiments, and it is anticipated that the completed tests will have an important bearing on Rand mining economics. Mr. Hamilton referred to the improvements that have taken place in Rand metallurgical practice, and specially alluded to the removal of the amalgamating plates from the mill-house to a separate building, the use of zinc-dust as a precipitant, and the installation of vacuum filtration plants at the Crown Mines, Robinson, Bantjes, Brakpan, and Modderfontein properties.

Interesting reorganization work is being carried out at the Crown Mines property. The extent of the Crown Mines claim area from east to west on the strike of the reef is nearly three miles, and there are on the property nine main

shafts and seven crusher stations. In the past, ore has been raised through all these shafts and each of the crusher stations has been utilized. Since the amalgamation of the several properties, which now constitute the Crown Mines Ltd., it has been decided to reorganize not only the plants but the scheme of working, and, with a view to economy and efficiency, one of the first items in the new program is to be concentration of hoisting and crushing at two stations only. Two shafts, known as the No. 5 and No. 7, in future will be the main haulage pits of the property, and at each of these crushing operations will be carried out. By systems of underground chutes and haulage all rock from the Langlaagte Royal, Paarl Central, Langlaagte Deep, and western areas will be concentrated at the No. 7 shaft and hoisted there, while ore from the Robinson Central Deep, Crown Deep, Crown Reef, and eastern areas will gradually be concentrated at shaft No. 5. These two shafts will be connected on the 13th level at a vertical depth of approximately 2200 ft. by a main haulage drift 14½ ft. wide, and practically straight from one end of the property to the other. This drift will be served by electric haulage. The two shafts will have to handle between 9000 and 10,000 tons per day as the full requirements from the mine.

MEXICO

Cost of Production at Cananea. — Consolidations in Chihuahua. — Alvarado Reduction Plant.— Veta Colorada Mill. — Reorganization of Mexico Consolidated.

During the remainder of this year the Cananea Consolidated Copper Co. (Greene-Cananea) expects to produce copper at a cost of 9c. per pound. Last year the total cost was 11.19c., but this included a construction cost of 1.49c., leaving the operating cost 9.7c. per pound. The construction program, inaugurated a few years ago, has been completed at a cost of over $7,500,000, and there will be no further construction charges this year. The operating cost will cover new development. The operating profit of Greene-Cananea in 1910 is placed at $1,300,000, and construction costs at $650,000, leaving a balance of $650,000. The production in the year amounted to 45,771,925 lb. of copper, 1,187,820 oz. of silver, and 5483 oz. of gold. The ore handled in the 12 months amounted to 969,728 tons. The mines formerly owned by the Hidalgo Mining Co., in the Parral district of Chihuahua, have been taken over by the Alvarado Mining & Milling Co. at a price of $500,000. These mines, and control of the Parral & Durango railroad, were acquired a few months ago by those principally interested in the Alvarado enterprise, the deal involving, according to reports, $1,500,000. To make the purchase of the mines, and to pay off notes of the Alvarado Consolidated Mines Co., the concern that was merged with the Palmilla company in the organization of the Alvarado Mining & Milling Co., the present company has issued $1,000,000 of 5-year 6% convertible gold bonds. The new reduction plant of the Alvarado is handling from 250 to 300 tons daily, and it is hoped to increase to 400 tons daily during the present year. The dump ore at the Palmilla mine and at the mines of the Hidalgo company is sufficient to keep the plant busy for a long period. Development below the water-level in the Palmilla mine will have to await the erection of a powerful pumping plant. The company plans to develop an ore reserve sufficient for several years before enlarging the reduction plant. The new plant of the Veta Colorada Mining & Smelter Co., near Parral, is operating steadily, and bullion shipments are being made. The tanks of the Veta Colorada plant were planned by Bernard MacDonald, the Guanajuato cyanide expert, and have been given the name 'Parral tanks.' They are of unusual size, and new principles of agitation are involved. The results so far have been very satisfactory, according to report. The time for depositing securities under the latest plan for the reorganization of the Mexico Consolidated Mining & Smelting Co., of Boston, owning mines and a new reduction plant in the Guanacevi district of Durango, has been extended to April 21.

NEW YORK

Awaiting Supreme Court Decisions.—Competition of Copper Producers.—Sulphuric Acid Manufacture.—Alaskan Developments. —South Utah Mines.—Tooele, Tintic, and Pioche.

In a general way, the waiting attitude prevailing throughout the East has become intensified. There is nothing on foot in the way of bringing out new issues. It is said that the house of J. P. Morgan & Co. alone has nearly a billion dollars of consolidations and industrial promotions awaiting a construction of the Sherman law. It is hard to realize the extent to which the coming Supreme Court decisions affect Wall Street. Every Monday, if the Supreme Court at Washington is sitting, sees a busy group of customers watching the tickers. It is the rule now in the New York financial district that offices filled on Mondays are uninhabited for the remainder of the week. It is undoubtedly in the hope of securing a new and more active following among small traders that the Stock Exchange has taken in several of the leading new copper issues, such as Nevada Consolidated, Ray Consolidated, and Chino, which are soon to be followed by Miami and Inspiration.

That the copper situation is not clearing itself as rapidly as was hoped is shown by a recent move on the part of the Guggenheim coppers to compete with the Tennessee Copper in the making of sulphuric acid. Utah Copper and Nevada Consolidated are, up to the present time, the leaders in the porphyry group, and, as such, are in a class alone as large producers of cheap copper. It is significant, therefore, as an admission of the competition among these copper producers and of the gravity of the situation in view of the new properties just ready to put copper on the market, that the American Smelting & Refining Co. should begin to look forward to and prepare for the day when the net profits will be derived from by-products. The A. S. & R. Co. people have been examining phosphate beds throughout the West with a view to utilizing the phosphate in the manufacture of fertilizer, if a market can be found for the product. Experimental leaching plants are in operation at both the Nevada Consolidated and the Utah Copper properties, and if the experiments result satisfactorily an attempt will be made to recover the copper from the oxidized overburden and from the tailing dumps. Tennessee Copper's sulphuric-acid plant is making about 500 tons daily. This output is about 80% of what the plant is expected to produce when all the operating problems have been solved. It is expected to show a profit of about $3 per ton. Inasmuch as the plant was really erected as an expedient to rid the company of endless litigation over its smelter fume, it appears to have been a real turning of loss and annoyance into an actual profit. It may yet be that Butte, Bingham, Tooele, and Douglas, instead of being centres of areas devastated of vegetation, will not only overcome the fume problem, but will be the source of rejuvenation for the lands of the West which have been exhausted by unwise cultivation without rest or crop rotation. In a way, it would be a duplication of Nature's chemistry as illustrated by the finest vineyards in the world growing in the volcanic ash near the crater of Mount Vesuvius.

Undoubtedly a part of the promotions mentioned as held up in the office of J. P. Morgan & Co. is represented by the Copper River railroad and the Bonanza mines in Alaska. The railroad has just been completed, and the first shipments of copper are expected to be made in the very near future. It may have been something more than a construction of the Sherman anti-trust law which deterred the house of Morgan & Co. from making any public offering of the Alaska enterprises. In the face of the copper situation it would have been futile in any event, but it is also true that there exists in the public mind a well-defined idea that, while the Morgan-Guggenheim syndicate has been performing some great feats in Alaska, such work has not been disinterestedly for the good of the territory.

Mr. Heinze's operations in Porcupine are hailed as ex-

tremely successful. and, indeed, the first promotion of his new enterprises in that camp seems to have moved off without a hitch. In the meantime, however, it is expected that Mr. Heinze will be altogether eliminated from Ohio Copper before the next annual meeting in June. Mr. Heinze's ability to create enthusiasm in new promotions and enlist support among strangers, and his propensity for getting snarled up in litigation, is a pat illustration of the old saying that it takes a bigger man to complete an undertaking than it does to begin one.

The South Utah Mines & Smelters, which is a reorganization of the Newhouse Mines & Smelters Corporation, has settled the claim of the United Metals Selling Co., for $144,000, in full. The South Utah company ships its concentrate to the Tooele smelter, and is adding new equipment to its mill in an effort to lower production costs. The copper output is sold by E. P. Earle, who is also very largely interested in Cobalt and more recently in Porcupine.

It is expected that the erection of the new lead stack at Tooele will greatly improve the situation of the lead-silver producers in Utah. The Tintics have quite a following in New York, while the camp at Ploche has just as many followers, though the latter have been mostly heart-sick from deferred hope.

LONDON

Kolar Mines.— Decrease in Costs at Mysore. — Report for 1910 at Nundydroog.—New Properties.—Successful Year at Ooregum. — New Methods Employed.

Since writing last week of the Mysore Gold Mining Co., the most important of the Taylor group of mines in the Kolar district of India, the news is published that the decrease in costs of operation has made it possible to treat great amounts of ore that have hitherto been left in the stopes, so that it is not only the discoveries at depth that have to be followed by the shareholders. Two other mines of the same group have published their reports for 1910. The Nundydroog shows a position of high current profits and future prospects like the Mysore. The Ooregum has made its largest recorded profit, but development is not so promising for the future. Some details of these mines will be of interest.

The Nundydroog company was first formed in 1882, but no satisfactory results were obtained until 1898. Since then the output has steadily increased, with the exception of 1898-90, when a lean zone was passed through. The report for 1910 shows that 91,000 short tons was sent to the stamps and that 81,293 oz. bullion was extracted by amalgamation. In addition 84,280 tons of tailing yielded by cyanide 7436 oz. bullion. The total production of gold was worth £334,748, the working cost was £153,813, royalty to the Mysore Government £18,984, income tax £7221, depreciation £10,773, amount placed to reserve £20,000, and dividend £117,916, being at the rate of 41⅔%. This dividend is the highest yet paid, a result which is not fully appreciated until it is recollected that all expenses formerly charged to capital account are now being paid out of revenue, and also that a reserve fund is being built up. Other items of note are that the additional ground acquired from the Tank Block is proving useful in facilitating development, that the price paid for electric power to the Cauvery Falls company has been reduced, and that the ore reserve has been increased to 141,296 tons during the year. The superintendent, Charles H. Richards, gives a detailed account of development at various points and draws special attention to the valuable discoveries on the 2450, 2600, and 2750-ft. levels in Kennedy's section. Mr. Richards also reports that he has been investigating the question of treating the large accumulation of slime and that he expects to make a definite proposition in the course of the current year. Two years ago the company acquired an option on the Jibutil block in the Anantapur goldfield, Madras Presidency, and since then W. T. Stonor, the superintendent, has pushed development. His report is incorporated with the Nundydroog report, showing that the shaft has been sunk to 450 ft. and levels have been driven at 130, 250, 350, and 450 ft. The ore reserve is 21,200 tons, and in all the levels indications are good. The directors have therefore decided to complete the purchase and to float a separate company to purchase and work the property.

The other company, the Ooregum, began producing in 1888 and the first dividend was paid in 1891. It is not so large a property as the Mysore, Champion Reef, or Nundydroog, and it has passed through more vicissitudes. The last period of low-grade ore was from 1905 to 1907, but in 1909 the gold content once more rose and averaged 12½ dwt., as compared with 8¾ in 1905. The report for 1910 shows that 133,407 tons of ore was sent to the mill, and yielded 80,934 oz. bullion; in addition, 122,051 tons of tailing yielded 12,833 oz. bullion. The total production was 34,151 oz. fine gold. The extraction per ton was about 12¾ dwt., practically the same as in 1909, and the total yield was the largest in the history of the company. The income from the sale of gold was £357,119. The current expenditure was £175,157, royalty £20,270, income tax 7286, depreciation of plant £6000, allocation to cost of new shaft £9000. A reserve fund has been started with £15,000 out of the year's profits. The dividends absorbed were £129,250, being 42½% on the £120,000 preference and 32½% on the £240,772 ordinary. The working costs have been reduced during the year, being 26s. 3d. per ton, as compared with 29s. 5d. in 1909, hence the possibility of paying an increased dividend and starting a revenue fund. The amount of development work done during 1910 was 16,298 ft., and the reserve on December 31 was 164,534 tons, a slight increase during the year. The general results were not quite so good as expected, but R. H. P. Bullen, the superintendent, reports that he will be able to maintain the present yield during this year. The deepest workings are 4210 ft. on the dip. For some time the directors have discussed securing other property, and the opportunity has recently been presented of taking a three years option on claims twelve miles to the north of the Kolar district. This property contains ancient workings in which a vein has recently been discovered 60 ft. from the surface. The Ooregum company plans to spend £5000 in exploration work.

Another gold mine under the auspices of John Taylor & Sons is the Mount Boppy at Cobar, New South Wales. It has been producing gold since 1901 and yielding dividends since 1902. The metallurgical equipment contains 40 stamps that were acquired from the Gallymont company. The ore near the surface was oxidized, showing the usual secondary enrichment, and the profits to 1908 were large. During the years 1905 to 1908 the dividends were 47½% on a capital of £121,000. Subsequently the oxidized ore decreased in value and the workings penetrated sulphide, but nevertheless the dividends were 27½% in 1909 and 35% in 1910. The report for 1910 shows that 47,082 tons of oxidized and 31,608 tons of sulphide ore were sent to the stamps, and 11,199 oz. was caught by amalgamation. In addition the cyanide plant extracted 17,937 oz., and 317 tons of concentrate, sold to smelters, yielded 2314 oz. The total production was therefore 31,486 oz. (8 dwt. per ton), which sold for £132,048. The working cost was £79,685, income tax £3191, depreciation £4042, and allocation to capital expenditure £3000. The dividend distributed absorbed £42,350, bringing the total distribution to date to £395,382. The directors intend to alter the metallurgical methods, in order to obtain a higher extraction from the sulphide ore. It is proposed to adopt the all-sliming method, and a new plant, consisting of tube-mills, agitators, and filter-presses, is to be provided. Experiments show that by this means an additional pennyweight can be extracted per ton, giving on 80,000 tons per year an increased yield of £16,400. The superintendent, James Negus, reports that development at depth, toward the south end of the property, indicates that the two orebodies which at the northern end are like the two legs of an inverted saddle, have come together and partake of the nature of an ordinary fissure vein. There is therefore a prospect of an extended life for the property. The ore reserve was 234,684 tons on December 31, an increase of 9000 tons during the year.

General Mining News

ALASKA

KETCHIKAN DISTRICT

(Special Correspondence.)—The Mt. Andrew mine, one of the best producers in this district, has been bonded to the United States Smelting, Refining & Mining Co., at $2,500,000, the first payment of $1,000,000 to be made on July 1 this year, when, if the bond is taken up, that company will take full charge.

P. Heaney, in charge of the Victory, on Seal bay, reports good progress. The main tunnel is now in 1900 ft., and raising and driving is also being done on this property. Operations at the It mine have commenced again, and the ground prospected last season with the diamond-drill will be opened this year by driving an adit about 1300 ft. long. Returns from the last shipment of ore from the Rush & Brown mine showed an average of about 7% copper and $4 gold per ton. The vein of high-grade sulphide ore will be prospected on the 200-ft. level by a cross-cut now being driven from the main shaft. A number of prospectors are preparing to explore the Salmon river country, near the British Columbia boundary line, as several good-looking croppings were discovered there last season.

Ketchikan, March 30.

PRINCE WILLIAM SOUND

The Valdez *Prospector* reports that steps have been taken at that place to put a stop to the practice of staking claims on ground while it is so deeply snow-covered as to make the discovery of a vein or lode impossible. The unfairness and absence of good faith in staking a large area of country when it is covered by 10 ft. of snow serve to discourage legitimate prospecting and to restrict *bona fide* locations.

The first shipment of copper ore was made from the Bonanza mine at Kennicott last week. It amounted to 2000 tons, and was hauled to Cordova over the Copper River & Northwestern railroad, and thence by steamship to the Tacoma smelter. A shipment of 30,000 bbl. of fuel oil, produced by three wells in the Katalla field, was made for Seattle on April 5 by the Amalgamated Development Company.

THE TANANA

Winter sluicing was performed successfully in March by Peterson & Kellum, who are operating on 17 Goldstream, out from Fairbanks, having a lease on ground belonging to L. L. James and H. H. McDonald. The first clean-up, made after an 8-day run, amounted to about $5000, gold to this value having been taken from 2150 sq. ft. of bedrock. Sluicing at that season of freezing weather was made possible by covering the sluice-boxes and heating the interior by steam-pipes; the water, before being turned into the flume, was also heated by exhaust steam. This firm was employing 31 men in March, this force having been engaged in blocking out the ground, timbering, and building flumes. When the regular season opens, May 1, a force of 120 men will be employed. All the material on bedrock will be handled with cars this season instead of wheelbarrows. The pay-dirt is found on bedrock, 50 to 65 ft. below the surface, and is reached by vertical shafts through which the gravel is hoisted to the surface for sluicing.

ARIZONA

COCHISE COUNTY

The Copper Queen Con. Mining Co., operating at Bisbee, the Detroit Copper Co. at Morenci, and the Moctezuma at Nacozari, comprising the three copper companies controlled by Phelps, Dodge & Co., made net earnings of $6,190,092 in 1910, distributed as follows: Copper Queen, $4,623,856; Detroit, $1,085,545; Moctezuma, $480,690. The Copper Queen company operates at Douglas the largest copper-smelting plant in the Southwest, where ores from its Bisbee mines, concentrate from the Moctezuma mill, and a large tonnage of custom ore and concentrate are smelted. The Detroit company operates a concentrator and smelter at Morenci.

MARICOPA COUNTY

The Arizona Mines Co. has sunk a 250-ft. inclined shaft on the foot-wall of a vein said to have a width of 40 ft., containing ore of good grade, carrying copper, silver, and gold. The intention is to continue sinking till a depth on the 40° incline of 450 ft. is reached. The property is situated on Castle creek, out from Wickenburg. F. X. O'Brien has sunk a 200-ft. shaft, and has driven 500 ft. on a 20-ft. vein of sulphide ore, at his property in that vicinity. In the latter, sulphide ore has been found.

GREENLEE COUNTY

The Arizona Copper Co., the copper mines of which are in the vicinities of Metcalf, Longfellow, and Morenci, produced 32,210,000 lb. of copper during 1910, at a cost of 10.3c. per pound. Its ore is said to have yielded an average of 42.64 lb. of copper per ton. Close to 96% of the ore produced was concentrated, the remaining 4% having been smelted direct. The company has three concentrating mills at Clifton, and one at Morenci; the smelting plant, as to its original unit, was built at Clifton more than 20 years ago, although it has been enlarged and portions of it rebuilt several times. But it is now announced that a new smelter is to be built. In addition to its milling and smelting operations, this company for many years has made use of a leaching process for treating low-grade oxidized ore, using sulphuric acid that is manufactured from the sulphurous fume emitted in the roasting sulphide ore. This leaching plant has been considered a pronounced commercial success. In connection with it is a plant for the manufacture of bluestone, or copper sulphate. The home office of this company is at Edinburgh, Scotland.

YAVAPAI COUNTY

The Monte Cristo mine, near Constellation, being developed by Ezra W. Thayer of Phoenix, is attracting attention by reason of the finding of a 14-in. vein of ore assaying high in silver. The ore consists of chloride of silver and lead carbonate.

The Congress gold mine, for years one of the best producers in Arizona, is reported closed down. It has two veins, on one of which an inclined shaft was sunk on the dip of the vein to a depth of 3300 ft. The surface equipment includes two mills and a cyanide plant. The mine is believed to be nearly worked out.

(Special Correspondence.)—Lewis & Ardria are shipping 10 tons of high-grade gold and silver ore per day to the Humboldt smelter. The United Verde Copper Co. has acquired of J. S. Jones the Independence mine, at Chaparal This property is a producer of siliclous ore, much desired at the United Verde smelter. The Henrietta mine, situated near McCabe, is reported operating again. The ore is being sent to the smelter. A carload of ore was shipped recently from the Oro Belle mine, near Crown King, which sampled about $100 gold per ton; another car was shipped from the McKinley mine, situated in the same locality. The latter was of low-grade ore.

Prescott, April 4.

YUMA COUNTY

The mine belonging to W. E. Scott, on the Goodman lode, in the vicinity of Quartzsite, has been developed by a 125-ft. shaft and 175 ft. of driving on the vein. The ore mined and treated in a small Nissen stamp-mill during the last few months yielded between $9000 and $10,000 in gold. The last clean-up, which resulted from milling 25 tons of ore, amounted to about $1500. The Goodman lode croppings are traceable for 1500 ft. This lode is at the head of a gulch containing the old La Paz placer claims, where some placer mining is still in operation. A property containing cinnabar ore is being developed with a force of 10 men, directed by George Cheney, in that vicinity.

CALIFORNIA

CALAVERAS COUNTY

Ralph King, James B. Maguire, and others are preparing to work the Three B. claim on Calaveras river. This ground contains a deposit of auriferous gravel having a width of 100 ft., a depth of at least 60 ft., and of undeter-

mined length. A pit, made by excavating, is kept free of water by a water-power siphon, and a hoist is to be placed there to be used in raising the gravel to the dump-hopper, at the head of the sluices. Water for sluicing is to be obtained from the Mokelumne canal. Two gold dredges are in successful operation at Jenny Lind, and the San Andreas *Citizen* states that another dredge is to be built there. An electric-car line, which is being built from Stockton to Jenny Lind, may be in operation by July 1.

ELDORADO COUNTY

The Murdock gravel mine, situated on Nigger flat, four miles from Placerville, has passed under bond to Idaho and Washington operators, who expect to work it this season. The property is said to contain an ancient river channel, the gravel bed of which is rich in coarse gold. This stratum of auriferous gravel lies beneath a lava capping, and is so well cemented together as to require a crusher and stamps for pulverizing it, so as to free the gold before passing the material through sluice-boxes. P. K. Kelsey, of Lewiston, Idaho, who is concerned in the bond given, is now in

Map of California.

charge. The present mill has five stamps, and a larger mill may be built if operations shall prove as successful as anticipated. The drift being driven on the Helena gravel mine, near Georgetown, by Robert Waugh and Archie Goldberry, now has a length of 900 ft., and the drift heading soon is expected to reach the gold-bearing channel.

KERN COUNTY

The Randsburg *Miner* reports that the cyanide annex to the Osdick 5-stamp mill, in Stringer district, has been put in operation, with Charles Overmyer in charge. The first material to be leached consists of 2000 tons of tailing that has accumulated, and similar material from other mills of the district will then be treated. The Yellow Aster M. & M. Co. has finished the work of straightening and retimbering its Bonanza shaft, which is situated east of the big glory-hole, and has a depth of 335 ft. A cross-cut to be 600 ft. long is to be driven from this shaft toward the axis of the mountain, by which the orebody will be opened at a depth of 1000 ft. Other cross-cuts are to be driven in the opposite direction to explore ground south of the main orebody. A 2000-ft. tunnel is being driven through to the hill to serve as a haulage level for the delivery of ore to the mill. The Atolia Mining Co. is successfully operating a tungsten mine near Atolia. P. Fahey, operating the Windy mine, near Randsburg, recently sent 50 tons of ore to Red Dog mill. Half of this was taken from the 140-ft. level. The Phoenix mine, at Johannesburg, owned by C. A. Burcham of Randsburg, is equipped with a 5-stamp mill, which is in operation. An interior shaft is to be sunk to a depth of 500 feet.

NEVADA COUNTY

(Special Correspondence.)—At the Champion mines 80 men are employed, of whom 20 are on the pay-roll of the North Star Mines Co. The latter is opening new levels and sampling the various orebodies exposed. Its bond on the Champion continues for six months, and it appears to be satisfied with developments thus far conducted. The Champion Mining Co. is concentrating work in the vicinity of the 800-ft. level and running the mill on ore from this place. It is reported that operations are to be resumed at the Murchie mines, situated in a proved section of the Nevada City district, and which recently passed into new hands. The new 3-compartment shaft at the Brunswick mine has reached a depth of 450 ft., and sinking is to be continued as soon as a new 600-gal. pump has been put in place. The Brunswick has been idle for two years, pending the completion of the new shaft, which will intersect the old workings at a depth of 1000 ft. The mine lies in the same gold belt as the Idaho-Maryland group.

Nevada City, April 8.

The North Star mine, the widely known gold property at Grass Valley, mined and milled 90,110 tons of ore during 1910, of an average value of $13.68 per ton. The gross proceeds for the year amounted to $1,232,933; cost of operating and development was $555,860, leaving a profit of $677,073. The North Star Mines Co., which owns the property, paid $403,471 in dividends within the year, and placed $554,526 in the investment account. The manager for the company is A. DeW. Foote.

PLACER COUNTY

The Beaver Dredge Co., of Los Angeles, is constructing a gold dredge on the Hawk ranch, near Rocklin, to replace the one of lighter construction used last season. The new dredge is to cost $125,000. Pendleton brothers, who are driving through cemented gravel in the Laird mine, at Yankee Hill, east of Loomis, have taken out some material that runs $100 per ton.

PLUMAS COUNTY

The Rose Quartz gold mine, on Poorman's creek, which is equipped with a mill and ditches and flume for a water supply, has been leased for three years to Hattie E. Churchill of Sacramento. Operations at the property are to begin this spring, with Julia Kelley as superintendent. Some development work is to be performed to open ore-shoots, and new equipment may be provided for the mill.

SAN BERNARDINO COUNTY

The smelter of the Needles Mining & Smelting Co., which has been enlarged and improved generally, is ready to operate again. A large tonnage of ore has been accumulated. The concentrating plant has undergone some changes, and when it is started again its processes will consist of wet concentration for making a lead product, followed by drying the iron-zinc middling and separating those two metals by Huff electrostatic machines, similar to those in use at the United States company's plant at Midvale, Utah. D. R. Muir is manager for the Needles M. &. S. Company.

SIERRA COUNTY

The Gold Canyon mine is under bond to E. M. Parrish, who came into possession of the property last fall. In sinking a winze 25 ft. below the drain tunnel rich ore was found in what is believed to be the same shoot as that which yielded high-grade ore in early days. The Omega gravel mine, situated near Forest, which is leased to the Electric Separating Co. of Oakland, is being developed with a force of 24 men, who are extending drifts through the channel of blue, cemented gravel which has fine gold disseminated through it. This tight placer material is pulverized in the mill, and the gold is recovered by electro-chemical machines which were put in by L. J. Neuamont of San Francisco. W. A. Hussey of Oakland is

manager for the company, with W. W. Casserly in charge of the mine.

TUOLUMNE COUNTY

(Special Correspondence.)—T. J. Benny, superintendent of the Lone Star group of mines, situated northwest of Confidence, and owned by J. W. Watters of Santa Cruz, will put things in readiness for the resumption of operations. Several adits have been driven on the veins to determine the merit of the property, and it is now the intention to start a cross-cut at the lowest point of the mountain, where the mill is situated, to tap the veins at great depth. It is estimated that between 300 and 400 ft. of cross-cutting will have to be done. Besides the gain of several hundred feet of backs, the proposed adit will be the means of materially reducing the cost of moving the ore to the mill. The extensive improvements being made for several months at the Jumper have been completed and mining activity again prevails. The entire mill, consisting of 60 stamps, is not yet in operation, owing to some unfinished repairs, but will be in a short time. The working crew is being increased as fast as possible. The Street mine, at Tuttletown, is being unwatered, and it is expected that development work will be commenced by May 1. Underground work has been resumed at the Berkley and the new 10-stamp mill started. Between 20 and 25 men are employed. It is reported that operations are to be resumed at the Hazel Dell mine, and that the Hyde and Keltz will also be re-opened and worked. The properties are on the East lode. A new head-frame has been erected at the Mazeppa, and development work is in progress with a crew of 10 men. The development of the Hull mine, near Big Oak Flat, is to be resumed. The four 5-stamp batteries, recently purchased by the operators of the Dutch mine, have been delivered at the property and will be put in position soon. The addition will double the present capacity of the mill.

Tuolumne, April 8.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—J. L. Cutting, leasing on the second level of the Gold Dirt mine, on Covode mountain, shot into a body of ore 3 ft. wide, the ore assaying 7.8 oz. gold per ton. The Columbia and Eureka mining claims, on Silver mountain, have been taken under bond and lease by J. H. Meinhart, of Denver, who has commenced work. The adit on the Sporting Times vein, Alpine mountain, is being driven to cut under the old shaft that is down 150 ft. Drifting is also in progress on the Moore vein, a 4-in. streak of galena being followed that is worth $45 per ton. A shipment of 50 tons of lead-zinc ore was sent out this week from the East Griffith mine to the Newton mill at Idaho Springs for concentration. Ericson & Co. are operating under lease. In milling 400 tons of ore from the Aetna vein, at the Capital mine, $4000 was realized. Of this sum $1900 was taken from the amalgam plates. It is reported that the Centennial mine, on Leavenworth, has been sold to W. M. Cooper, representing a syndicate of Pennsylvania men. The consideration is given at $125,000.

Georgetown, April 3.

(Special Correspondence.)—It is stated that the Gold Quartz mine at Alice will be equipped with a 25-ton mill by W. A. Maxwell of Brighton. Shipment of 700 tons of ore is being made from the Refugee mine to the Hudson mill for concentration. T. H. Rowem, who recently purchased the mine, is to develop the property thoroughly. After a temporary suspension, operations were again begun last week on the Saratoga mine, and shipments are being made to the Golden smelter. The mill at the Lombard mine, up Ute creek, will be started this month. Extensive development is in progress through adits 3 and 4, and large reserves of concentrating ore are exposed. Henry I. Seemann is manager. All of the machinery for the Kattie Emmett mill has been delivered, and W. W. Cannady, the manager, expects to have the plant in readiness to start ore-treatment this month.

Idaho Springs, April 3.

GILPIN COUNTY

(Special Correspondence.)—Work is to be resumed on the Fourth of July mine. The machinery is being overhauled and placed in good condition. R. L. Martin is owner. H. Peck has the contract to put up a shaft-house on the Gilpin-Coatey mine at Black Hawk. The machinery was ordered from Stroehle & Co. Large development is in progress at the Anchor mine, that recently passed to the North American S. & M. Co. It was announced this week that the National group of mines had been taken under bond and lease by the last-named company, the price specified being $300,000. Heavy shipments are going out from the Chase mine, operated by the Gilpado M. Co. The ore is of a smelting grade and brings from $87.80 to $280.90 per ton. A shipment of 25 tons of ore from the Egyptian mine brought a settlement of $21.50 per ton in gold and silver. Ben Anderle is operating under lease. The shaft on the Topeka mine, in Russell district, has attained a depth of 1500 ft. As soon as a sump of 40 ft. has been completed, driving will be started from the 1400 and 1500-ft. levels.

Central City, April 2.

LAKE COUNTY (LEADVILLE)

The Mt. Champion Gold M. Co., which has been doing development work all winter with a force of 16 men, has its property on Lackawana gulch opened by an 1800-ft.

Central Colorado.

cross-cut, the greater length of which is in a deposit of ore, which, according to the *Carbonate Chronicle*, is free milling, and assays $10 per ton in gold. It is claimed there is 30,000 tons of ore exposed. The company is to build a 9000-ft. tramway from the mine to the millsite. Machinery and other equipment is being hauled to the property by way of Half Moon gulch. The Sugar Loaf Con. M. Co. is continuing to drive its tunnel toward the Virginius claim, and when the objective point is reached a raise will be driven from the tunnel to the old Virginius shaft, thereby obtaining good ventilation. The old workings of the Virginius will be explored and further developed. Ore of shipping grade has been found in the tunnel where it intersects three veins. The Garbutt, on Breece hill, now has a 700-ft. working shaft. A cross-cut was driven from the No. 3 shaft of the Ibex group into Garbutt ground, and a 200-ft. raise was made to the Garbutt shaft. A large tonnage of ore has been blocked out on the different levels, the ore having been developed on four different fissures, the dips of which are bringing them closer together. The

ore now being mined is said to have an assay value of $45 per ton in gold and silver. The Empire Zinc Co., in control of the Colonel Sellers zinc mine, on California gulch, is expected to begin shipping ore from this and other mines of the district as soon as its zinc smelter in Oklahoma shall be completed, which will probably be within the next six weeks. Henifen & Reynolds, who operate the Louisville zinc mine through the Yak tunnel, are shipping 35 tons of ore daily. The Sunday mine, at the head of California gulch, is producing 500 tons of lead ore per month. This ore carries some gold. The property is in the hands of lessees. A body of ore recently found by a lessee on a block of Ibex ground is said to sample 40% zinc carbonate.

SAN JUAN COUNTY

The Peerless San Juan mine, on Minnie gulch, between Silverton and Eureka, may be operated again this season. It has been idle by reason of dissension among the directors of the company. The property has been opened by two adit-levels, the lowest of which was driven 800 ft.; by this a depth on the lode of over 2000 ft. is attained.

SAN MIGUEL COUNTY

Information received by the Telluride *Journal* is to the effect that the Ballard mine, situated on Bear creek, has been sold to those who are likely to re-open the property and operate it this season. The Ballard has a strong vein of good-grade ore, and was a profitable producer 25 years ago. It had lain idle many years by reason of litigation. Bear creek joins the San Miguel river opposite Pandora.

HINSDALE COUNTY

An ore-reduction plant, equipped for putting into practice the Rankin process, has been built at Lake City.

IDAHO

IDAHO COUNTY

The Elk City *Mining News* states that Tiedeman and Bosch, who own the Golden Rule placer property, situated five miles up-stream from Elk City, are preparing for hydraulic operations this season. Their ditch takes water from the west fork of American river, and they obtain some water from smaller streams. The necessary pipe-line is in order, and work will begin early. It is learned from the same source that the Jumbo mine, in Buffalo Hump region, is active, and that 10 stamps in the 20-stamp mill are operating; and that the other 10 stamps will be in use later. H. E. Gray sold his interest in the Jumbo lease to Bathurst and Shonecker.

SHOSHONE COUNTY

The discovery of a new ore-shoot is reported to have been made by driving a drift on the vein about 1000 ft. from the main ore-shoot, on No. 4 adit level of the Hercules mine, at Burke. The drift has been extended 75 to 100 ft. on the new orebody, disclosing ore of milling grade, and some galena of a grade that will stand shipping. Stringers of ore have been found in a 180-ft. drift, at 120 ft. depth, in the property of the Ajax M. Co., which adjoins the Hercules. The Stewart company, operating the Stewart mine, near Kellogg, is reported to have paid all of its indebtedness, and it has a surplus of $70,000. It is stated that a mill will be built. The ore being produced at this mine is being concentrated in a leased mill. John H. Nordquist, in charge of the Idora mine, is reported as stating that a 9-in. body of clear galena has been opened in an intermediate level, 60 ft. below No. 2 adit. By the side of this streak is a much larger body of ore of milling grade. There is, also, 6 ft. of milling ore opened on a second intermediate level, 180 ft. below No. 2 adit.

MONTANA

LINCOLN COUNTY

The Snowshoe mine, a lead-silver property, situated 20 miles south of Libby, which belonged partly to the Noble estate, and partly to persons of North Yakima, has been sold to E. H. Wilson, of Oakland, and his associates. The sale was due partly to the efforts of P. L. Eberhardt, of Wallace, Idaho. The Snowshoe, during the time it was operated, five to twelve years ago, produced ore of a value of about $1,000,000, but it has been idle for the last three years. The mine is opened by means of a 450-ft. vertical shaft, the levels from which, extending toward the centre of the mountain, attain a much greater depth on the vein. The surface improvement consists of hoisting facilities, shaft-house, shop, and a concentrating mill of about 200 tons capacity. The railroad of a local lumber company, which extends to a place within eight miles of the mine, is to be built five miles farther, and this will afford good transportation facilities. The Snowshoe ore contains lead, silver, gold, and iron, the concentrate making a high-grade sulphide product. It is stated that Mr. Wilson will employ a force of men later in the season and take charge of operations.

SILVER BOW COUNTY

(Special Correspondence.)—The Pilot-Butte Mining Co., controlled by Tuolumne interests, will resume operations on the property in May. The report comes from the Elm Orlu mine, owned by W. A. Clark, that the rich vein on which mining is being done in that property, has been opened to the north side-line of the Pilot. The latter is

Western Montana.

surrounded by the Butte & Superior, Elm Orlu, North Butte, and Anaconda mines. The Pilot was formerly in the hands of inexperienced men, but those now in control, including Edward Hickey and his associates, have always been successful in their mining operations. Machinery for the mine has been ordered. While the shaft is being sunk it is purposed to cross-cut the zone at a depth of 1600 ft. from the Butte & Superior workings, the latter company having given permission to work through its property; and the intention is to raise on the Pilot shaft from the 1600 at the same time that sinking is being done. Patrick Sheehan, superintendent of the Tuolumne, will have charge of the work on the Pilot.

Butte, April 8.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—It is stated that the new management of the National Mines Co. has decided to adopt a more liberal development policy, relative to the district, than has hitherto prevailed. This is supposed to mean that lessees will have better opportunities to operate on this remarkably rich ground. National ranks third among gold and silver camps in Nevada, principally due to the production of the National Mines Co. J. L. Currier of New York has purchased the Jersey mine for $250,000. The property is situated in Jersey valley, 90 miles south of Winnemucca, and comprises 22 claims. The ore is gold bearing. It is stated that a new company will be formed to operate the mine, and that a 50-ton concentrating plant will be built within a few months. The Adamson-Turner

mine, on the north side of Winnemucca mountain, has an orebody said to be nearly 3 ft. wide, containing rich ore. A winze is being sunk on the ore. At the Seven Troughs Coalition 75 men are employed, and the mill is operating at full capacity. On the fifth level the vein is 6 ft. wide, the ore running as high as $100 per ton. The mill is unable to handle all the ore produced. The Signal Peak, situated near the Mazuma Hills and Seven Troughs, has been operating since last December, and ore-shipments will soon commence to the Darby mill at Mazuma. The Nineteen-Ten, Barret Springs district, is shipping steadily.

Winnemucca, April 6.

LINCOLN COUNTY

The stockholders of the Prince Consolidated, the Ohio Kentucky M. Co., and the Nevada Utah Mines & Smelters Corporation have authorized the directors of their respective companies to carry out plans recently made for the merging of all the interests named, which means the consolidation of a number of the largest mines of the Pioche district, under the name of the Amalgamated Pioche Mines & Smelters Corporation. The properties included in the consolidation comprise the Nevada Utah, the holdings of the Prince Con., the Ohio Kentucky, Greenwood, and the narrow-gauge railroad which extends from Pioche to the Day mine, at Jack Rabbit.

STOREY COUNTY

The three principal north-end mines on the Comstock lode, Virginia City, had an output for the week ended March 25 as follows: The Ophir produced 487 mine-cars of ore of an average value of $26.58 per ton, amounting to a total of $12,945; the Mexican produced 129 mine-cars averaging $50 per ton, making a total of $6570; the Con. Virginia's output was 216 cars, averaging $9.87 per ton, aggregating $2132. The principal extraction from the Ophir was from the 2100-ft. stope on the Hardy vein; that from the Mexican was divided, the ore coming from the 2300 and 2500-ft. levels; the Con. Virginia ore was taken from the 1800-ft. stope, principally.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The body of milling ore, recently discovered in the winze that was sunk from the fifth level of the Enterprise mine has been opened by a cross-cut at greater depth. The mill at the Deadwood mine is being brought to higher efficiency each week. The last clean-up amounted to 2500 oz. of gold and silver bullion; there was produced, also, 15 sacks of concentrate. The mine is being unwatered, and a larger force of miners will be employed later. The clean-up made last week by the Ernestine M. Co. was 7030 oz. of gold and silver, recovered from 680 tons of ore. A company is being organized to develop property known as the Iron claims, situated close to the Gold Dust group, three miles from Mogollon.

Mogollon, April 4.

OREGON

BAKER COUNTY

The Baker ore-sampling plant, owned by the Oregon-Idaho Investment Co., which was destroyed by fire April 1, is being rebuilt.

GRANT COUNTY

The Canyon Mountain M. Co., now having control of the Jack Chambers mine, close to Canyon City, has commenced driving an adit-level on the vein in which pay-ore is exposed, and is to equip a small mill in which to treat the ore. Among those interested in the mine are C. J. Bingham, Jack Chambers, Harry Craig, F. S. Slater, and M. Stockdale, of Canyon City.

UTAH

SALT LAKE COUNTY

The ore reserves of the Utah Consolidated, locally known as the Highland Boy, are now placed at 381,000 tons. The 1910 ore production was 182,204 tons, which yielded 41.15 lb. copper, 0.84 oz. silver, and $1.63 gold per ton. Special attention is being given to the development of that part of the property heretofore little explored; to better accomplish this a 3-compartment interior shaft is being sunk from No. 7 haulage level at a point about 1500 ft. from the portal.

TOOELE COUNTY

The Galena King Mining Co., for which Duncan MacVichie is manager, is to be operated again. The work of putting the shaft in good condition is in progress. The mine is situated at Stockton, and in former years was a profitable producer of lead-silver ore. It has a 1000-ft. shaft, the workings connected with which are caved to some extent, requiring considerable work to be done before regular mine work can be carried on. The litigation that was pending between this company and the Honerine has been settled. The earliest mining operations in Utah were at Stockton, and the first lead smelter in that State was built there. It is a district in which there are a number of developed mines, and today there is evidence of a revival of activity. The Honerine has a large extent of development, including a drain and transportation tunnel over 2000 ft. in length.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Activity in the mines of Republic district is increasing. New people are coming in with money to invest, and mining properties are changing hands. The Copper Bell, one of the earliest patented locations, said to cover the southerly extension of the San Poil vein, has been sold to E. Orr, of Spokane, who will organize a company and proceed with development. Work on the Ben Hur mine has been resumed, with seven men cleaning up and getting ready to break ore. The winze below the 285-ft. level is being unwatered. The force is to be increased to 15 men; and beginning with the first week in April the Ben Hur Leasing Co. expects to ship three carloads of ore per week. At the Hope mine, now in charge of W. W. Robbins, a small hoist has been installed at the head of the winze, for development of the Black Tail vein below the adit-level. The winze will be sunk to a depth of 300 ft. below the adit. Driving is in progress on ore on the No. 2 level of the Knob Hill mine, from which 30 tons of ore per day is being taken. The value now averages about $35 per ton. The San Poil Consolidated Mining Co. has employed ten men during the past week, and shipped two carloads of ore to the Granby smelter. The North San Poil raise is now up 80 ft., all the way in good ore. At the head the ore is 7 ft. wide between the walls. On account of bad air only one shift is at present employed. The new machinery will be installed within 30 days.

Republic, April 7.

CANADA

BRITISH COLUMBIA

The Mollie Hughes mine, a producer of silver and gold ore, situated at New Denver, has been sold by Michael Zatoni to a syndicate of Spokane men. The property comprises seven claims, and has been developed by several adits, so connected that the ore can be delivered from the lowest level to barges on Slocan lake. Considerable ore was shipped from the mine during the last two years, the smelter returns from which are said to have shown an average value of $54 per ton.

MEXICO

CHIHUAHUA

(Special Correspondence.)—J. Gordon Hardy, consulting engineer for La Republica M. Co., reports that during February 1025 tons of ore was milled, the revenue derived therefrom having amounted to ₱65,257. Operating costs and expenditures for development amounted to ₱44,037; construction expenses, ₱2542. Conditions under which operations continue are trying, and the ordinary means of transportation are practically paralyzed. The mine is at Sanz, some distance from Ocampo.

Ocampo, March 29.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

STATUTE MAKING MINE OWNER LIABLE FOR NEGLIGENCE OF MINE FOREMAN IS UNCONSTITUTIONAL

The section of the Pennsylvania statute of 1891, providing that for any injury occasioned by violation of the act, for failure of the mine owner to comply with its provisions, a right of action shall accrue to the party injured against such owner for any damages he may have sustained, is unconstitutional in so far as it imposes a liability upon the owner of the mine for failure of the mine foreman to comply with the statute.

Dempsey *v.* Buck Run Coal Co., (Penn.) 76 Atlantic 745. March 1910.

INJURY TO MINER—ASSUMPTION OF RISK

An experienced driller and miner was employed to enter different rooms in a coal mine and drill the face of the coal so that it could be shot and removed. After the coal had been thus drilled or cut in a particular room a number of men called 'loaders' would shoot down the coal by blasts and load the same on cars in which it was removed from the mine. When the driller had finished in one room the machine would be rolled into another room, and so on until all were cut or drilled. It was understood that he would cut or drill in the different rooms in the order in which the drilling or cutting was needed for the purpose of keeping the 'loaders' engaged in shooting and hauling out the coal. After the coal was thus drilled or cut and shot down and removed from the room it was the duty of the 'loaders' to prop the roof of the room with props furnished by the mine owner, to make it safe for the driller, who had nothing to do with the propping or protecting the roof. After each drilling or cutting and shooting and hauling out of the coal the props would be advanced to within 10 or 12 ft. of the bank or the face of the unmined coal; or if the roof was bad or dangerous the props would be placed closer to the face of the unmined coal, the idea being to regulate the location of the props by the condition of the roof of the mine, and to use as many props and in such places as the condition of the roof might demand. The driller was not directed to enter any particular room at any particular time, but the method of the work of drilling or cutting was to enter the rooms in order and as fast as the coal was shot and removed from the different rooms. While thus working in a room in which the props were placed some 12 ft. from the face of the coal the driller was injured by falling rock from the roof because of the improper propping. In an action for the injuries it was held that the driller did not assume the risk because he was not directed by the mine owner to go into the particular room, as he entered such room according to the system of work. It was held also that the mine owner owed the duty to the driller of keeping the place safe, as the driller was not charged with the duty either of making the place safe himself, or of inspecting it to see if it was safe. Neither could the mine owner escape liability as a matter of law because he had delegated the authority to the loaders to make the place safe, and their judgment that it was safe was conclusive. Nor was the driller prevented from recovery by reason of the statute of Kentucky which provides that any person employed in a mine who wilfully neglects to prop the roof of any working place under his control shall be liable to a fine, etc., as such statute was not applicable to the driller, for the reason that he was not charged with the duty of propping the roof. It was held it could not be said that the driller was injured in the work of making the place unsafe, so that the mine owner would not be liable for the injuries, since the injuries occurred from the failure to properly prop the roof, which had no connection with the work of the driller, and was done by an entirely different set of working men.

Williams Coal Co. *v.* Cooper, (Ken.) 127 Southwest. 1000. May 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. P. HAMMON is in New York.

C. E. JULIEN will be in New York next week.

J. R. FINLAY was in San Francisco this week.

C. W. MERRILL has returned to San Francisco.

R. D. GEORGE was at Jackson, California, last week.

EDMUND JUESSEN was in San Francisco last Saturday.

FREDERICK H. MORLEY was in San Francisco on his way back to Denver from Honolulu.

SIMONDS & BURNS have moved their offices from 60 Wall street, New York, to 55 Liberty street.

R. S. RAINSFORD is manager at the Jumbo mine as well as for the Argonaut Mining Company.

F. A. BROWN is in the Cripple Creek district, Colorado, examining mining properties for Eastern people.

M. J. FALKENBURG, of Falkenburg & Laucks, is in the interior of British Columbia on professional business.

THOMAS G. LOCKHART, general manager for the Florence-Goldfield M. Co., Goldfield, Nevada, is at San Francisco.

WILLIAM S. MANN is building a stamp-mill and cyanide plant for the Pilones Mining Co., at La Portilla, Durango, Mexico.

ATHOLL F. MCEWEN sailed on the *Baltic* April 8 from New York for Europe; he expects to be gone about three months.

W. F. FERRIER has been appointed general manager for the Natural Resources Exploration Co., Ltd., of Canada, with headquarters at Toronto.

W. CLAYTON MILLER, general manager for the Federal Mining & Smelting Co., operating in the Coeur d'Alene district, Idaho, was at San Francisco this week.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January and February, 1911:

	Tons.
Imports of copper	29,407
Exports of copper	1,271
Consumption of copper	28,136

as compared with consumption during the same period in 1910 of 28,370 tons. Of this quantity, 25,536 tons were imported from the United States.

Company Reports

PHELPS, DODGE & CO.

This report summarizes the reports for 1910 of the Copper Queen Con. Mining Co., Detroit Copper Mining Co., Moctezuma Copper Co., Burro Mountain Mining Co., and the Stag Cañon Fuel Co. The holdings in these companies amount to $48,987,640, the capital stock of Phelps, Dodge & Co. consisting of 450,000 shares of a par value of $100 each. The receipts of the company for 1910 were $9,099,-909.53, of which $252,520.99 was the expense of operation of the company; $5,399,875 was paid in dividends and $3,447,513.54 was added to the surplus. The total production of the Copper Queen Con. Mining Co. for the year was 12,430.27 oz. gold, 608,096.95 oz. silver, 76,428,908 lb. copper, and 696,118 lb. lead. The Detroit Copper Mining Co. produced 23,056,292 lb. of copper. The Moctezuma Copper Co. milled during the year 447,555 tons of ore, of an average content of 2.992% copper, and produced 107,-104.6 tons of concentrate, containing 22,603,218 lb. of copper. The Stag Cañon Fuel Co. produced 1,381,457 tons of coal in 1910.

DALY-JUDGE MINING COMPANY

During the year ended January 31, 1911, this company mined 56,108 tons of ore, of which 9106 tons of an average value of $26.14 per ton was sold in the crude state, and 47,002 tons was subjected to concentration. This produced 7787 tons of concentrate, of an average value of $28.45 per ton, 2511 tons of iron middling worth $12.94 per ton, and 10,556 tons of zinc middling worth $5.69 per ton. The total cost of operation was $7.35 per ton, of which $4.76 was the operating cost and $2.59 the cost of exploratory work. The net profit for the year was $94,177.05, and a payment of $36,000 was made for three years drainage privilege through the Ontario tunnel. The report does not convey any idea as to the worth of the property, as it makes no mention of the number of shares of stock issued, nor does it give any statement as to the amount of ore in reserve, the so-called financial statement being merely a profit and loss account. No provision is made in this for depreciation of the property and equipment.

STANDARD CONSOLIDATED MINING CO.

The report of this mine, situated at Bodie, California, for the year ended February 27, 1911, shows that during 1910, 14,010 tons of ore was mined, and 14,528 tons crushed in the stamp-mill, and $70,402 recovered in the form of amalgam, the cost of treatment being $1.63 per ton and the average extraction being 41.45%. The tailing from the mill was treated in the cyanide plant, together with 23,570 tons of old tailing, the average value being $6.21, of which 83.74% was recovered. The ore reserve is 3275 tons, of an estimated value of $50,000. The dividend for the year was $17,839.40, making a total to date of $5,211,970, corresponding to a total production of bullion of $15,900,520. The company possesses valuable water rights that are capable of being developed into a large source of revenue as soon as a satisfactory market for power has been developed. An excellent feature of this report is the detailed monthly statements of cost of operations, notably the cost of development and stoping in the different veins.

EL PASO CONSOLIDATED GOLD MINING CO.

The report of this company for the year ended December 31, 1910, shows that the receipts from ore sales and other sources amounted to $561,103 and the expense of operation was $512,486. A further payment of $37,098 was made on account of drainage and amortization. Dividends amounting to $49,000 were paid during the year, leaving a surplus of $429,691 in the treasury, but there is no statement as to the character of this surplus, except an incidental reference to the purchase of $80,000 worth of Drainage Tunnel stock. It would be well to include a full statement of this item constituting the surplus. The number of shares issued is 2,450,000 of a par value of $1 each. During the year 8262 ft. of development has been done, with an increase in the ore reserve. Twenty-four sets of lessees are at work, of whom 15 are actually producing ore. The drainage adit is draining the lower levels of the mine, opening them up for exploitation on company account, as the lessees are at work only above the fourth level. The report reflects great credit upon the president, A. L. Burris, and the management, for the energy and skill with which they have brought the mine through a critical period in its history.

WARRIOR DEVELOPMENT COMPANY

During the year this company mined and sold 31,450 tons of copper ore of an average copper content of 9.65%. This was sold to the El Paso smelting works during the first half of the year, and to the old Dominion Copper M. & S. Co. for the latter half of the year, on the basis of 90% of its copper content. The average cost of production was 8.74c. per pound of copper, of which 4c. was the smelting cost. This corresponds to a profit of $2.69 per ton of ore smelted. The company is capitalized at 50,000 shares of $10 each; 5000 fully paid shares are outstanding, and $4 each has been paid on 40,150 shares. The property consists of three groups of 275.5 acres of patented claims, 41.2 acres on which patent is proceeding, and 841.57 acres of unpatented claims. Of the purchase price of the property, $124,940 has already been paid; $30,880 is to be paid from earnings during 1911 and 1912, at the end of which period a further $1,120,000 is to be paid, either $850,000 or $350,000 of this sum being payable in bonds at the option of the purchaser. The report says that there has been an increase in the amount of ore blocked out ready for stoping, but the amount is not given. A contract for smelting the ore on more advantageous terms has been made, and the shipments will be increased to 125 tons per day. The company is operating the property under a bond and lease.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

S. L., Oasis, California: Clay shale.

J. M. D., Atwater, California: Gypsum in a clay limestone.

M. J. O., Denio, Oregon: The specimen is molybdenite with quartz.

E. E. N., Nogales, Arizona: No. 1, olivine basalt; No. 2, amygdaloidal basic lava.

O. F. W., Robinson, Utah: One specimen is quartz and the other an indurated clay.

R. H. B., Takilma, Oregon: No. 1, psilomelane pebbles: No. 2, chromite; No. 3, red hematite; No. 4, earthy limonite or ocher.

T. C. C., Nogales, Arizona: No. 1, cleavage pieces of rhodochrosite with quartz; No. 2, pyrite in chlorite schist; No. 3, pyrrhotite in quartz diorite: No. 4, hornstone; No. 5, manganese dioxide, pseudomorph after rhodochrosite.

W. J. W., Parsons, New Mexico: Most of the samples are too much altered to make definite determinations possible. They appear to be alterations of similar kinds of rock, probably syenite or monzonite. No. 1, highly kaolinized volcanic; No. 2, weathered surface piece of syenite; No. 3, fine grained syenite, showing pink feldspar, magnetite, and chloritized hornblende; No. 4, kaolinized syenite with chalcedony seams; No. 5, altered syenite; No. 6, a weathered piece of the rock which is suggestive of phonolite.

COMMERCIAL PARAGRAPHS

THE AMERICAN METAL CO., LTD., announces the removal of its Denver office to the A. C. Foster building, Sixteenth and Champa streets.

FALKENBURG & LAUCKS, chemists and metallurgists at Seattle, have established an ore-testing plant which contains such equipment as is necessary in making tests by all standard processes.

The AMERICAN LOCOMOTIVE CO. announces that on April 8, 1911, its Chicago office was moved from Railway Exchange building to suite 907-912 McCormick building, Michigan boulevard and Van Buren street.

THE PACIFIC TANK & PIPE CO., of Los Angeles, reports that its San Francisco office has just sold the Rawhide Queen mill a complete cyanide plant for a ten-stamp mill in Rawhide. It is expected that the entire plant will be delivered on the ground within thirty days and will be in complete running order by June 1.

J. W. SWAREN has opened offices in the Shawmut building as advertising consultant, handling engineering advertising only. Mr. Swaren had a broad engineering experience before taking up sales work, and has been advertising manager for several San Francisco manufacturers. There is a broad field for this work in San Francisco.

Jesse Scobey has purchased an interest in the HENRY E. WOOD ORE TESTING CO., of Denver, and is now vice-president and secretary of the company, associated with Henry E. Wood, president. In connection with their regular assaying, chemical, and ore testing work, they will act as consulting engineers in the design and equipment of milling plants and as managers and agents of mining properties for foreign investors.

The DORR CYANIDE MACHINERY CO. reports among recent sales three thickeners and one classifier sold to the Portland Mining Co., of Colorado Springs, Colorado. The Dorr Mines Syndicate of the Porcupine district, Ontario, is installing four Dorr classifiers and seven Dorr thickeners in its new mill. The Vulture Mines Co., of Wickenburg, Arizona, reports that the Dorr continuous thickening process in use there is operating with little or no personal attention.

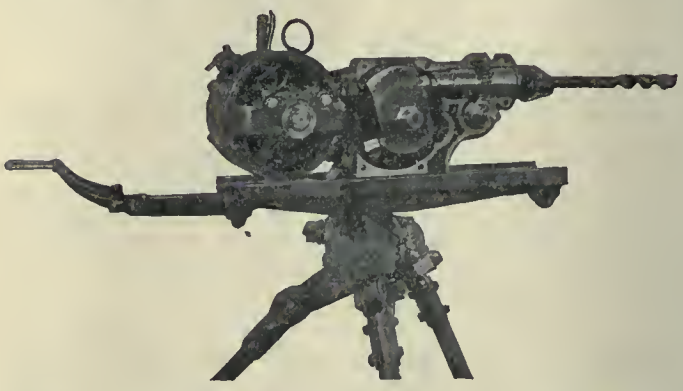
THE HAMMOND IRON WORKS has recently taken over the business of the Hydraulic Cyanide Agitation Co. of Warren, Pennsylvania. The patents for the Paterson agitation tanks have been assigend to the Hammond Iron Works for the United States, Mexico, and Canada. This company has recently received an order and shipped to the Exploration company of England and Mexico for its Santa Rosa mines in the State of Zacatecas, four Paterson agitation tanks. The Paterson tanks have been put on a working scale in London and are showing some wonderful results.

The revival in mining due to the use of improved metallurgical equipment is well reflected in the large number of installations made by the OLIVER CONTINUOUS FILTER CO. of San Francisco. Filters have recently been placed in operation at the following plants: Two at the Trinity Gold Mining & Reduction Co., Carrville, California, handling an exceptionally impervious oxidized slime; two at the Empire Mines Co., Grass Valley, California, operating on classified slime; one at the Pittsburg Liberty Mine, Masonic, near Bodie, California, handling a re-ground product; one filter has just been installed at the Treasure Mining & Reduction Co., Clear Creek, New Mexico. The installation of this filter was a record breaker for prompt delivery, being shipped seven days after the order was placed, and ready for operation twelve days after arrival on the ground. Filters for the following companies are now being built: Nevada Wonder Mining Co., Wonder, Nevada; Candalaria Con. Mexican Mining Co., San Dimas, Durango, Mexico; Maricopa Mines Co., Austin, Nevada; Cia. Minera Jesus Maria y Anexas, San Jose de Gracia, Sinaloa, Mexico. The last named is a repeat order, this company having had two Oliver filters in operation for two years.

THE FORT WAYNE ROCK-DRILL

The great advantages of electrical power as a means for driving rock-drills has caused many efforts to be made to develop an electrical drill of a type suited to actual working conditions. Many devices have been tried, but failed to accomplish successfully and economically the desired approximation to the combined striking and rotating action of hand-drilling; the problem of converting the rotation of the electric motor into the reciprocation of the drill proving too difficult of solution. A simple and ingenious method of solving the problem has been devised and employed in the construction of the Fort Wayne rock-drill, which has recently been placed upon the market.

This drill is of the rotary-hammer type, operated by an electric motor which is mounted on the frame of the drill proper. The mechanism of the drill consists of two parts, a revolving helve containing the hammers, and the chuck mechanism for holding and rotating the drill steel. An idler is conveniently arranged in connection with the flexible belt between motor and drill, which provides a means of regulating the speed of the drill. Thus all the advantages of hand-drilling are obtained without the disadvantages usually incident to machine drilling.



The drill steel is held in the chuck by means of several spring-steel plates. When not striking rock, the blow from the hammer is absorbed by these buffer plates, and they also retain the steel in the chuck while 'backing out' of deep holes or in broken and uneven ground. The drill casing, striking mechanism, chuck, and buffer plates are all simple and very substantial. The floating hammers in the helve are of special steel and are completely cushioned by air chambers so that the jar of the impact is reduced to a minimum. The drill steel cannot be jammed into a fissure or cleavage crack for two reasons. Should a fissure be encountered the buffer head prevents the drill steel from being plunged forward. The drill steel is not reciprocating, and before it can be fed far enough into a fissure to wedge, it has hammered for itself a square shoulder or face, due to the rapidity of the blows on the constantly rotating drill steel. The resultant effect approaches that of boring.

Another point of excellence in the Fort Wayne drill is the simple method employed for the removal of cuttings from the hole being drilled. A specially designed steel, illustrated in the figure above, removes the cuttings by boring action and does away with the use of hollow drills or water under pressure. Thus the large expense of pressure systems, including tanks, hose, water lines, etc., is eliminated, as well as the cost of maintenance and inconvenience incident to such systems. While these drills are ordinarily used in a horizontal position, they may be used in any position and will drill holes at any angle. The ease with which power can be transmitted throughout the workings by wire and the rapidity with which the lines can be changed enables the operator to advance his work more rapidly than could be done when using other types of drills.

A comparison of tests of the Fort Wayne drill and air-drills shows that the former requires about 1½ to 2 hp., including transmission loss, while an average air-drill requires from 15 to 20 hp. for the same work. This is due to the design of the drill, the much greater efficiency of the electric motor, and the small loss in transmitting power to the drill. The simplicity and strength of design of this drill is a guarantee that the cost of maintenance will be exceedingly low. Owing to the saving in power, the low cost of maintenance, and the high efficiency of the Fort Wayne drill, from 50 to 70% can readily be made, under ordinary conditions, upon the investment. The drill can be operated with either an A. C. or D. C. motor, and since the motor is entirely independent of the drill the change from one to the other may be easily made. An 8-page bulletin describing the machine in more detail can be obtained from the Rock Drill Department of the Fort Wayne Electric Works, Madison, Wisconsin.

MAYO MEAN EFFECTIVE PRESSURE TABLES

The calculation of the mean effective pressure of Corliss engines, both single cylinder and compound, operating under condensing and non-condensing service, has always been a tedious mechanical process. While any one may calculate this mean effective pressure by means of standard formulas, engineers have usually avoided this work, with the result that the figures have never become thoroughly standardized. It often happens at a contract-letting where from eight to ten engine-builders are represented, that each builder offers an engine of a different size, which is not only inconvenient for the engine-builder, but results in delays and confusion to the purchaser as well.

The Hooven-Owens-Rentschler Co., of Hamilton, Ohio, has recently issued two tables neatly gotten up with celluloid covers, by means of which the mean effective pressures for the different types of Corliss engines, and therefore their horse-power can easily be obtained. The object of these folders was to get some uniformity in ratings among engine-builders. They will be found of much interest to engineers and others connected with the generation of steam-power by reciprocating engines.

Each set of tables consists of a celluloid casing with a transverse slot near the end, at the side of which the various gauge pressures are printed. Within this casing is a scale upon which the number of expansions or points of cut-off are marked, together with a table of mean effective pressures. It is readily seen that by sliding the scale until the desired number of expansions or percentage of stroke at cut-off is immediately under the opening provided for it, there will be found adjacent to the steam pressure the correct value for the mean effective pressure.

One table gives the results for single cylinder engines, both condensing and non-condensing; the other for compound condensing and non-condensing engines. For condensing operation a vacuum of 26 in. is assumed, but a constant is given which can be added or deducted for variations from this vacuum. Gauge pressures of from 50 to 200 lb. are tabulated. The compound engine table shows results of any number of expansions between 5 and 27.

These tables will be furnished to anyone interested by applying to Chas. C. Moore & Co., Engineers, San Francisco.

A. LESCHEN & SONS ROPE CO.

In a paragraph published in our issue of March 25, relating to the building of an 8500-ft. aerial tramway for the Standard Silver-Lead M. Co., at Silverton, B. C., it was stated that the contract to build the tramway had been let to B. C. Riblet, while as a matter of fact it had been let to A. Leschen & Sons Rope Co., of St. Louis, through the Leschen representative, W. S. Riblet, of Nelson, B. C. The error arose from the fact that Mr. Riblet was formerly in the business of building tramways, and the fact that the Riblet patents and other property were purchased a number of years ago by A. Leschen & Sons Rope Co. had been overlooked.

The Chicago office of the Atlantic Equipment Co. was on April 8, 1911, moved from the Railway Exchange building to suite 907-912 McCormick building, Michigan boulevard and Van Buren street.

GOLD, literally by the ton, is being produced by the Goldfield Consolidated Mines Company, a recent shipment having weighed 2138 pounds.

DISPUTES relative to the proper form of entry for phosphate claims on the public land seem not likely to be determined soon, since the cases in controversy at Salt Lake have been settled out of court.

THE MIAMI MILL began operations upon unusually low-grade ore, so that the poor results in 'warming up' the mill might be upon poor ore. Since Mr. J. Parke Channing has begun with so sensible a refinement, we may continue to look forward with interest to many useful lessons to be learned from ore-dressing practice at the mill under his direction.

SAN FRANCISCO members of the American Institute of Mining Engineers met at luncheon at the Palace Hotel last Wednesday to plan for the meeting of the Institute that is to be held in that city in October. An executive committee with Mr. W. C. Ralston, chairman, and Messrs. H. F. Bain, F. W. Bradley, E. H. Benjamin, S. B. Christy, and M. L. Requa as fellow members, was selected. Mr. Bradley will act as chairman of the sub-committee on session, Mr. Benjamin on excursions, Mr. Requa on finances, while Mr. Christy will be chairman of the reception committee, and Mr. Bain will be local secretary. Excursions probably will be arranged to the oilfields, to the dredging fields at Folsom, and to the Bohemian grove. It was also resolved, upon motion of Mr. Luther Wagoner, that the local members should effect a permanent organization and provide for meetings annually or oftener as might prove feasible. The matter was placed in the hands of the executive committee and no doubt a strong local organization will result. This will, we are sure, be helpful to the community and the parent society.

SALE of a half interest in the Vinegorone fraction to the Goldfield Consolidated Mines Company for $195,000 has led to quiet discussion of the methods of valuing such ground. Last year Mr. C. S. Herzig examined the property for the Jumbo Extension Company and estimated the reserve at 73,000 tons of ore worth approximately $3,000,000. His estimates were widely criticized as excessive. Later Mr. G. F. Lewis made an estimate of 87,000 tons at $41 per ton. The sale was finally made on the basis of an appraisal, Mr. Albert Burch acting for the buyer and Mr. Walter Wiley for the seller. Allowing $5000 for development and $9 per ton for treat-

ment and metallurgical losses, the amount agreed upon is still startlingly less than the previous estimates led the public to expect. It is evident that there is a marked difference of judgment as to what is properly to be regarded as constituting an ore reserve. The difficulties of measuring and valuing deposits where the ore is high in grade and irregular in occurrence are admittedly great, but there should be no such discrepancy as noted. The burden of proof would seem to rest on the engineers making the larger estimate.

"ITALY," says a keen American engineer now traveling on the peninsula, "is a very different country from that depicted by the ordinary tourist with his nose in a Baedeker. The cities are modern, have clean streets, good trams, and steam roads; the hotels are clean and comfortable, with steam heat, electric lights, elevators, and all conveniences. The people are courteous, good-looking, well dressed, and well 'set up'. They show every sign of prosperity, and, while taxes are high and living not at all cheap, they are cheerful and proud of the progress made by United Italy—now just celebrating its semi-centennial. The country has a fine army and navy—every officer looks as if he were a picked man. Machine-shops and foundries are new, well designed, and well equipped. This nation is bound to realize its great future, and American engineers would do well to study European methods more than they do. By joining the best things here to what they have at home, an irresistible combination would be effected." It is a pleasure to quote this cheerful tribute to modern Italy, and at the same time to express the best of good wishes for the future of a country of which every American schoolboy learns the history, but whose present position in the industrial world is too little appreciated.

CHOICE through popular election is a poor way to select State mine inspectors. Mr. J. A. Holmes, director of the United States Bureau of Mines, put the matter nicely when he said in a recent address: "The State mine inspectors should have greater permanence in office and freedom from political and other outside influences. Their selection and continuance in office should depend upon their training and experience. They should be examined by a non-political board of mining men. They should be appointed upon the recommendation of such a board from the applicants that have shown the highest skill and best experience. Under no circumstances should they be selected by popular vote. In other words, politics should have nothing whatever to do with their selection or their continuance in office. The inspectors should have better support in the way of compensation. In fact, the salary and other conditions should be such as to enable the State to secure the best possible type of men for this important work." Inspectors should be impartial public officials, favoring neither the men nor the operators. We are glad to see that the Mining and Metallurgical Society of America has been agitating the matter of securing better and more independent inspectors.

TONOPAH has given geologists and engineers much to think over. The relations of the complex of igneous rocks in which the rich ores occur have led to dispute, the question being whether certain of the formations represented surface flows or intrusive sheets. If the former, it should be possible to follow the veins down into them; if the latter, the orebodies might be expected to be terminated by eruptive contacts. Repeated faulting has complicated the situation, already made sufficiently difficult by the close resemblance of the rocks of the different formations. Mr. J. E. Spurr, in his work for the United States Geological Survey, favored the thesis of the intrusive character of the disputed rocks. Mr. J. A. Burgess, as a result of his long work for the Tonopah Mining Company, developed the alternative hypothesis. During the last year Mr. Spurr has been re-studying the district at the instance of the various companies concerned, and his scientific results have now been made public. We print this week an abstract for which we are indebted to the courtesy of Mr. Edgar A. Collins, general manager for the Montana-Tonopah Mining Company. It will be seen that in the main Mr. Spurr continues to hold to his original hypothesis, and, while in the printed report the matter is not discussed, it is evident that following his conclusions, development must in the main continue to be directed to searching for faulted and floated masses of the 'earlier andesite' or 'Mizpah trachyte,' to use the new name. Perhaps the most interesting phase of the whole matter is the uniting of a number of independent companies to support such an unusually technical and scientific study.

Re-Location of Mining Claims

Our correspondents have taken decided exception to our former editorial comment on the question as to whether or not a locator has a right to re-locate his own claim after having failed to perform the annual assessment work required by law. The subject is of sufficient importance to merit further discussion. The Federal statute provides as a condition of the ownership of an unpatented mining claim that "not less than one hundred dollars worth of labor shall be performed or improvements made during each year," and that "upon a failure to comply with these conditions the claim or mine upon which such failure occurred shall be open to re-location in the same manner as if no location of the same had ever been made." The same statute also provides that if the original locator shall have "resumed work upon the claim" after failure and before re-location, an attempted re-location by another is ineffectual. We have, then, in the very statute prescribing the necessity of performing annual labor, a remedy provided by means of which a delinquent locator can atone for his failure to comply with the law. The question at once arises, is this method exclusive, or has the delinquent locator the same right possessed by third parties of making a new location and initiating a new title? It must be admitted that there is some authority supporting this idea, but a critical examination of the reason-

ing upon which the doctrine is based, leads to the conclusion that it is erroneous. It proceeds upon the theory that the original locator's title is terminated by the failure to perform the required annual labor. This premise is incorrect. The courts have repeatedly held that a failure on the part of a locator to perform his annual labor does not terminate his title. The Supreme Court of California has said: "The sole effect of such failure is to throw the land open to location *by others* and in the absence of such other location the original claimant's right to resume and hold his claim remains." If this doctrine is true and the location remains alive until an adverse locator steps in and takes advantage of the forfeiture (and there is but little question on this point), how can it be contended that the original locator possesses the right to re-enter his own claim, which still is in existence, to oust himself, as it were, in order to defeat the plain provisions of a salutary law intended to make every locator give evidence of good faith? This would allow a man to forfeit his own property in his own favor for the express purpose of evading the law. It has been contended that by making the new location the locator virtually abandons his original location. The very statement of this proposition answers itself. The attempt to make the new location is evidence of the strongest character that no real abandonment is intended.

Such eminent authorities on mining law as Lindley, Morrison, and Costigan, all favor the view that a delinquent locator should not be permitted to take advantage of his own delinquency by being allowed to re-locate. The Act of 1907, prescribing annual labor for mining claims in Alaska, specifically provides that a failure to perform annual labor renders a claim open to re-location "by others." The Supreme Court of the United States has said that the object of the law is to require every person who asserts an exclusive right to a mining claim "to expend something of labor or value on it as evidence of his good faith and to show that he was not acting on the principle of the dog in the manger." There are practical reasons why a man should not be permitted to re-locate his own claim and thus avoid the reasonable requirements of the law. He has the advantage of the situation, for he alone knows whether he is going to perform his assessment work or not, and can plan accordingly. By being in possession of the property at the expiration of the year he can resist the attempt of others to re-locate, for the law will not ordinarily permit any one to initiate a right by force as against a party in possession, and he can manage matters so that it is impossible for any one else to re-locate before he does. The law requiring the performance of annual labor is a wise one. Through all the ages mining laws have invariably required the performance of certain work as a condition of the retention of title. In some instances practically continuous mining was required. Many think that the existing Federal requirements should be increased, and it is certain that they should not be diminished. In any event they should be rigidly enforced, and the recent tendency of the courts seems to be in this direction.

Samuel Franklin Emmons

That geology is a young science, we are constantly reminded. S. F. Emmons, who died at his home in Washington, D. C., March 28, was born less than a dozen years after Lyell's 'Principles' had been given to the world; he graduated at Harvard in 1861, two years before Dana's 'Manual of Geology' was published; he studied, in 1862 to 1864, at the Ecole des Mines under Elie de Beaumont, one of the very founders of geology; he served on the first of the great National Geological Surveys; he was at one time or another the contemporary of practically every working geologist America has produced; and with it all he was the intimate personal friend of more than half of the young men in the profession. Literally hundreds came under his influence and owe something to him for direct inspiration or criticism. Beyond that, in the widening circle touched through common friends and printed page, his influence reached wherever economic geology is practised. In certain ways Emmons was the most influential geologist America has produced. With the possible exception of his chief, Clarence King, to whom he was always devoted, he came closest to mining engineers and mine operators of any of the men who have served the nation through work on the Geological Survey.

A trained mining engineer, with the best that Harvard, Paris, and Freiberg could give, he returned to America at the close of the Civil War, a young man of twenty-four, anxious to practise a profession then nearly unknown in America. His first commission took him to Missouri, where, amid the red clay and dolomite boulders, residual masses of galena were mined by most primitive methods; the forerunner of Missouri's present great lead industry. Other calls took him West, and his great opportunity came when he became one of the geologists of the Fortieth Parallel Survey. He entered upon his duties with enthusiasm and displayed ability of high order, so that at the close of the work he and J. D. Hague were King's principal assistants.

When the work of the Fortieth Parallel Survey was finally completed and the corps disbanded, Emmons started out to make a fortune. Adding to his savings funds advanced by personal friends, he bought cattle and herded them on the open range of Wyoming. It was a profitable business, but involved much hard work of which Emmons took his full share. It was difficult for those who knew him later to realize that the eminent and rather reticent scientist had once been a 'cowboy' and could ride, rope, and brand with the best of them, but in Wyoming there are stories yet of his life on the range. When, in 1879, the United States Geological Survey was organized and Clarence King was made director, almost his first act was to telegraph to Emmons the offer of a position. The lure of the old work was strong, and as soon as the cattle business could be sold to advantage, Emmons rejoined his chief. He was immediately placed in charge of the headquarters established at Denver, Colorado, and remained there up to the time the branch offices were abol-

ished, when he, with others, was transferred to Washington.

While living in Denver, Emmons accomplished three things, in particular, which have profoundly influenced the course of development of economic geology in America: (1) He planned and carried through a geological examination of the Leadville district; (2) he organized and directed the investigation of the precious-metal deposits for the Tenth Census; (3) through the Colorado Scientific Society and other agencies he brought about close personal relations between the scientific men employed by the Government and the mining engineers and mining men who were opening and operating mines. The result was to bring about an immensely stimulating and helpful set of reactions between science and practice. Geology was made practical and mining men were made to see that it was so. This, as much as any other one thing, has made possible the firm support that economic geology now has in the United States. At Leadville, Emmons and his associates centred their attention on structural studies. The fascinating problems of ore genesis were held to be subordinate to the practical problem of finding orebodies, and painstaking plotting of contacts and faults made it possible to accomplish results that, to many of the men then getting their first experience in following orebodies, were uncanny. Nowadays such work is common, and it is easy to overlook the marvel of it then. Emmons' less well-developed studies of the genesis of the Leadville deposits have been criticized; but the maps that accompany the Leadville monograph are standard today. Leadville in the early eighties was the great mining camp of the United States. Many of the present graybeards of the profession were then smooth-faced youths gaining experience there and laying the foundations of success and fortune. From Leadville they scattered to the ends of the earth and everywhere took with them the respect for accurate geologic work that Emmons had inspired. Through his work of the Tenth Census, too, Emmons exerted a wide influence. That Census is commonly considered the best that the United States ever has taken, and the number of men who began their professional work by digging up the exact facts that give it value, is surprising. All these men in the West came in contact with Emmons and he was ever a man to influence his fellows. He liked men and they reciprocated by liking him. So long as he remained at Denver, the office of the Geological Survey was the familiar meeting-place of geologists and engineers interested in developing the West. He was one of the three men, Mr. C. R. Van Hise and Mr. W. H. Weed being the others, who discovered and simultaneously announced the laws of secondary enrichment of ore deposits, and in 1894, at a time when gold mining was much depressed, he predicted the revival that so shortly followed. The roll of men who have served as his assistants includes most of the active men of the profession, and the list of papers he wrote, and of societies he honored and was honored by, is long. He remained active to a few days before his death, and as recently as March 18 we had the pleasure of publishing a notable discussion of the Cobalt deposits written by him. His fame was world-wide, and deserved.

Emmons gave freely of his services and advice and there is no question that had he cared to leave the Government service and undertake general consulting work he could have had for the asking an extremely remunerative practice. He, however, lived close to his ideals, and aside from the modest competence with which fortune favored him, had no apparent desire for money. He devoted his life to his profession, and it is appropriate that his fellow-engineers and geologists should erect some permanent memorial to him. To that end we have pleasure in quoting the following from a personal letter from Mr. T. A. Rickard:

"As you can imagine, the news of the death of Emmons means much to me. Apart from the loss of a personal friend, I appreciate keenly the tremendous service he performed throughout his life in applying geology intelligently to mining, and more especially in deciphering the structural geology of metal-mining districts in the interest not only of science but of industry. What Lyell did for geology as a whole, Emmons did for economic geology. Others have done splendid service, and are still doing it, but his Leadville monograph and the numerous papers he contributed to the Colorado Scientific Society, the American Institute of Mining Engineers, and to various technical journals, undoubtedly were the first publications to impress practical men with the value of geological research as applied to the making of money in mining. As a former resident in Colorado and as a mining engineer keenly interested in the geological side of our professional work, I was one of a great many to feel the stimulus of his writings. He did a public service, and it ought to be publicly acknowledged. Therefore I write to suggest that you, as editor of a paper devoted to the serious side of mining, should start a movement to perpetuate his memory by some useful benefaction. What form this should take may be left for future consideration. The endowment of a chair of economic geology at Harvard, his alma mater, or at the School of Mines in Colorado, the State in which he did his best work, might be appropriate. This may well be left to a committee, which should consist of men representing the intimate relation between mining and geology; for example, R. W. Raymond, James Douglas, James F. Kemp, F. W. Bradley, J. Parke Channing, Ben. B. Lawrence, Seeley W. Mudd (who knew him so well in his Leadville days), H. L. Smyth (of Harvard), David W. Brunton (as representing Colorado mining), George Otis Smith, director of the Geological Survey with which he so long served, J. A. Holmes, director of the new Bureau of Mines, and yourself. Of course, I would like to help in any way possible. Emmons had many friends on this side and they also are sure to be willing to subscribe toward a proper proposal to honor his memory and to perpetuate his good work."

We believe Mr. Rickard voices the feelings of many in what he writes, and, adopting his suggestion, we are asking the gentlemen named to join in forming a provisional committee to investigate the feasibility of carrying out the plan suggested.

The Development of Ore-Dressing Systems

By Frank E. Shepard

*In the quest for minerals there appear to be several phases of development, one leading into the other. The discovery of many of our large mining districts has resulted from placer workings in which the gold is found in gravels on or near the surface. The primitive methods with pick, shovel, and hand-rocker often served to develop rich deposits, then followed the more highly developed hydraulic mining systems involving greater expenditure of capital, but bringing greatly increased returns. This trail leads to a source and the patient prospector often reaches an outcrop or vein which requires deeper working with a more elaborate plant. The search is first for high-grade ores, for the difficulties of mine development, transportation, and treatment are great, and expenses proportionally high. Bonanzas, however, are rare, and afterward comes the patient search for ways and means of developing better methods of mining, milling, and smelting for making a profit from lower-grade ores. Refractory ores are found which call for more advanced methods of smelting, or the grade of ore is such that milling systems must be devised for concentrating sufficiently to permit shipment to smelting or refining points.

While the general trend of the value of an ore is from high grade to lower grade, there has also been an accompanying decrease of market price for the metals, which has called for serious study in all metallurgical systems. Ten years ago manufacturers of machinery for ore-reduction processes in the Rocky Mountain section, were devoting much attention to the details of smelting machinery for the treatment of high-grade ores. Today there is less call for smelting systems, and the demand appears for improved ore-dressing machinery for effecting recovery from lower and lower grade ores. This change from higher to lower-grade ore conditions has taken place generally throughout the fields of gold, silver, lead, zinc, and copper mining. The stamp-mill, with its amalgamating plates and bumping tables for the recovery of 50 to 70% of the gold and silver in the earlier period, is being succeeded by the concentration and cyanidation plants producing recoveries of 90% and over.

Lead-iron-zinc ores are presenting more and more difficult problems, and with the mining of lower-grade ores of these metals has come the demand for better methods of crushing, screening, hydraulic classification, and concentration, and great development in electrical processes for mineral separation has appeared in this particular line of ore treatment. The successful mining and milling of the great porphyry copper-ore deposits of a grade as low as 2% and under has brought about radical changes in milling methods, and concentrating mills of 10,000 tons daily capacity have been successfully developed. The tremendous growth of modern steel production has produced such demands on the iron ore supply that commercial possibilities have been found in the lower-grade iron-ore deposits of Michigan, and concentration plants have been installed for the treatment of 20,000 tons of ore per day. The call for economy in the Cripple Creek district has resulted in treating the dumps formed by the discarded ores of a former period, by means of modern concentration and cyanidation methods at the remarkably low cost of $1.50 per ton.

Those investing in mining enterprises have found that it pays to be guided by specialists in this line of work. Many mistakes are made by mining companies through hurrying the building of a mill before the mine is sufficiently developed. The professional fees of a competent geologist and mining engineer are well earned and thorough examination and sampling of the mine should be completed to furnish sufficient data from which to design and develop a suitable mill system. Having secured a representative sample of the ore to be treated, there are laboratories throughout the country where tests and experiments may be conducted and results obtained from which an economical system of ore treatment may be planned. The various manufacturers of mining and milling machinery offer engineering advice in the development of systems of ore treatment, and while this may be competent and the result of good practical experience, such advice depends upon data furnished by the mining company. Large mining companies appreciate the value of preliminary investigations of ore conditions in a mine and furnish the manufacturer reliable data from which to design and construct suitable machinery and equipment for the ore-dressing system: but in the smaller mining organizations, the building of a mill oftentimes appears to be more important than the development of orebodies, and the manufacturer is called upon to furnish machinery to treat ores which may change radically with further development of the mine. In extensive mining operations the plan is sometimes followed of erecting small mills to test the practical application of the mill system determined upon, and this proves of great value in solving difficult problems of ore treatment.

In the smaller mining companies, often composed of business men without any experience in mining or milling methods, it is seldom found that sufficient funds have been devoted to these important preliminary tests, and instead of employing competent technical advice some one of the directors of the company who 'has a liking for machinery' assumes charge of affairs, and the resulting mining and milling composition ends in minor chords. However small the proposed mining or milling installation, it is always advisable to secure the advice of a mining or metallurgical engineer who, after studying the entire field of operation and the economic conditions relating to mine and mill, making a suitable examination of the mine, and the necessary preliminary tests, submits general plans and specifications for a suitable mill system. While the manu-

*A paper presented before the Congress of Technology at the Massachusetts Institute of Technology, April 11.

facturers of mining and milling machinery are by custom expected to prepare plans for milling systems, on account of the stress of business competition, this is not a wise plan, and it is better practice to have one engineer thoroughly familiar with all technical matters from inception to the completion of the milling plant. The manufacturer has the very important part to perform of attending to the many details of mill installation, and it is his affair to keep up to the minute in all the improvements which aid in reducing costs and increasing the recovery from the ores.

Mill designing is a profession in itself. It is not necessary for the consulting, mining, or metallurgical engineer of the mining company to be an expert in the details of mill construction, as the machinery manufacturers make a study of these problems. The detailed drawings of the mill should be entrusted to an engineer who has not only a very thorough knowledge of mill-machinery details, but an intimate knowledge of mill-men and practice. In the selection of mill machinery the new, inexperienced mining company usually buys the cheapest grade, while the mill superintendent of long experience buys the best machinery that can be built. In a small mill treating 50 tons in 24 hours of an ore having a value of $15 per ton and assuming that the mill recovers 80% of the value, a delay in operation of but one hour means a loss of $25. It is manifestly poor economy to save a few hundred dollars in the original investment at the expense of several thousand dollars for delays and repairs.

Ore-crushers were formerly equipped with hard cast-iron jaw-plates which had to be removed every few weeks, whereas now these crushers are provided with the best crucible-steel jaw-plates which last for several months. Crushing-rolls were formerly equipped with cast-iron shells which gave short service and soon became grooved; now the best forged-steel, machine-finished shells are used with longer service and better product as a result. Elevating and conveying apparatus has reached a high state of development, all tending to greatly reduce the cost of handling materials. By means of these excellent modern devices the entire mill system is made automatic from beginning to end, excepting the adjustment of machinery.

One of the greatest, if not the greatest, improvement in the wet concentration of ores has been the important development in the preparation of ore previous to jigging and table-work as a result of the investigation of Robert H. Richards. Mr. Richards' devices for hydraulic classification of ore pulps, previous to table concentration, have produced savings over former methods amounting to hundreds of thousands of dollars annually. In the case of the small mill before mentioned having 50 tons capacity daily and recovering 80% of the value in $15 ore, an improvement in recovery of only 5% will mean an additional saving of over $12,000. Such improvements have actually been accomplished in practical mill systems using Richards' system of hydraulic classification.

The tube-mill is an important element in modern mill systems and was adapted from cement mill practice. It takes the place of the more complicated crushing machines involving the frequent renewal of shoes, dies, screens, and various parts in roller or Chilean mills and presents a simpler and more economical means for the fine crushing of ores. The development of the tube-mill in connection with the stamp-mill in South African practice is extraordinary; the combination effecting an increase in tons crushed per stamp from five tons, before the tube-mill was introduced, to twenty tons per stamp when assisted by the tube-mill. The better understanding of the preparation of ore previous to treatment on tables as well as the better understanding of the concentrating tables themselves has brought about great improvement in mill recoveries.

The development of magnetic and static concentrating machinery has allowed a practical separation of iron and zinc minerals which before was most difficult or impossible. Use has been made of the property of surface tension in liquids for the purpose of separating minerals from the attending gangue. In general, the sulphides of the metal may be floated on the liquid, while the gangue sinks. While the system is limited to certain conditions, it opens an interesting field, and one which may develop great possibilities. Even greater progress could be accomplished were it possible to obtain the earnest cooperation of mill operators. In some cases splendid triumphs have been accomplished because new devices have been given the 'square deal' by intelligent and progressive mill operators. On the other hand, many a mill system is undeveloped on account of personal prejudice and lack of initiative.

Failures in mill systems are too often due to the neglect to make tests to determine the points where losses occur or the costs of various operations. Changes suddenly occur in the ore, and if not promptly followed up with required changes in the mill system, will result in serious losses. One of the modern requirements is thorough sampling, and the best mills make use of automatic sampling throughout. It is most important to have the right spirit prevail among the members of the mill crew. Good team work tells here as well as in games, and a fair attitude and attention to improved methods of milling means thousands of dollars to the mining company.

We often see machinery advertised as 'fool-proof.' If the mill system is to be run by fools then we need fool-proof machinery, but if we can not advance beyond the stage of fool-proof machinery then we might as well give up our ideal of greater recovery. For the economical treatment of low-grade ores we must expect greater complication in the mill system, but if we can save $25,000 by the addition of some machine, even though not classified as 'fool-proof,' is not the expenditure warranted of $2500 in wages to some mill-man who will be friendly to the machine?

The man who stands by the machine has the opportunity of discovering many points, possibly improvements, regarding the operation or results of that machine. If the personal equation of that man is plus and he receives proper recognition by the man-

agement, the result is a substantial increment to mill development. Mills are usually built in remote sites, difficult of access, and in many cases at altitudes of 10,000 and 12,000 ft. above sea-level. It requires some financial incentive to induce good men to work constantly under these conditions, and liberal wages must be offered to obtain a high order of intelligence in the mill crew. The study of mill systems has in some cases shown a high order of inventive ability among mill superintendents in the development of devices for increasing the recovery of ore values, or reducing the expense of operation. There is, however, a great amount of blind prejudice to overcome when an attempt is made to introduce improved methods in the milling systems. This is a strange condition, for one would think that any millman would be favorable to any device which would show improved results even at the expense of some extra attention, but the fact remains that it requires a bitter fight to establish new systems.

A very interesting psychological fact exists in mill conditions. If a new device or system be introduced by some one of the mill attendants and he has the care of the device, that device is certain to work successfully. Should a system be introduced by the manufacturer, even though such system may have proved a success, all manner of prejudice and resistance appears, and often a good system is classed as a failure. If our graduates of technical schools could be induced to serve a few years of apprenticeship in a mill, and devote their technical training to assisting in the development of improved devices, good progress would be made for securing better ore-dressing systems. With the successful treatment of low-grade ores there must be better study of conditions, better skill in operation, and a constant effort for improvement. The modern mill calls for a higher order of materials of construction; concrete and steel are now being used where a few years ago their use was designated as an extravagance. Better machinery is being used and the use of higher-grade materials throughout the mill construction is considered a necessity.

The opportunity for improved results in ore-dressing systems is great. When it is known that in the operation of 10,000-ton copper-ore concentrators, the loss on every ton of ore treated is from 30 to 40%; that in precious metal wet-concentrating mills the loss is from 20 to 30%, the time is at hand when the data from long lines of investigation in assisting the engineer and the builder, added to the practical application of the honest mill-man, should produce some telling results.

Keeping a defective tool in operation does not pay; nor is it to the interest of the employee, particularly if he is paid by the job, to use imperfect apparatus which reduces his possible earnings. On the other hand, it is by no means seldom that workmen are found who have their choice of the best materials and apparatus and who possess the intelligence to apply these correctly, showing a striking disregard for their own safety and that of others, especially in framing structures of a temporary nature.

Magnesite in California

By Charles G. Yale

*The production from the magnesite deposits of California in 1909 was 9465 short tons crude, valued at $37,860, as compared with 6587 tons crude, valued at $19,761, in 1908. Aside from the increase in quantity in 1909, it is to be noted that there was an advance of 33⅓% in price of the crude ore, the average having risen from $3 per ton in 1908 to $4 per ton in 1909. The cost of producing magnesite differs considerably in different counties, owing to the diverse character of the deposits and the differences in the cost of carrying it to the nearest railroad. In some localities the ore is valued as low as $2.35 per ton at the mines; in others as high as $9 per ton. Where the merchantable ore occurs in small stringers, instead of in heavy homogeneous deposits, the cost of production is much increased. Moreover, where considerable development work is combined with that involving the extraction of ore, the cost increases, and it is not always feasible so to segregate the two factors of cost as to fix an exact valuation on the ore mined ready for sale. The price given is that at the railroad station nearest the respective mines.

Only seven mines in California were productive in 1909, and all but two of these are small, yielding a few hundred tons each. These mines are in Fresno, Napa, Riverside, Santa Clara, and Tulare counties, the most productive one being in Tulare county. The sale of the product of these mines is virtually limited to localities on the Pacific Coast, the cost of transportation to points of consumption east of the Rocky Mountains being prohibitive. The California magnesite can not compete in price at Eastern points with that imported from Greece and Hungary, whence shipments are made by sea and where cheap labor conditions prevail. Most of the magnesite produced in California is used in the manufacture of paper from wood pulp in the paper mills of California and Oregon. The quantity used for making artificial stone, tile, flooring, and building material is increasing each year. For these purposes and in paper manufacturing, only calcined magnesite is used. Crude magnesite is used only in manufacturing carbonic-acid gas, in the course of which process the magnesite is calcined and then is sold in that form. This calcined magnesite is sold generally at from $16 to $20 per ton, and it takes about 2 tons of crude ore to make 1 ton of the calcined material.

The few mines opened in 1909 were small, none of great importance having been developed to a producing stage. The county most productive in magnesite is Tulare, which has three mines, one of them the most important in the State. On this property calcining furnaces have been in operation for some time, and the entire output is calcined before shipment. The other two mines in the county are not equipped for calcining the crude ore.

---

*Min. Res. U. S., 1909.

The World's Greatest Silver Mine—Broken Hill

By John L. Cowan

Few of the world's 'big bonanzas' have given a better account of themselves than Broken Hill, in New South Wales, where silver-lead ores are quarried in open-cuts, like sandstone is in America; and where one remarkable mine (the Consols) has yielded incredible quantities of ore that ran 95% pure silver. And although silver mining on 'the Barrier' is greatly depressed, and the Cobalt mines have monopolized the attention of that part of the mining world interested in silver for several years past, the Broken Hill Proprietary is the largest silver producer in the world today. In the twenty-seven years that have elapsed since the discovery of 'the Barrier' (as the vein is called), its mines have paid more than $100,000,000 in dividends. They have yielded silver of a value of $300,000,000, to say nothing of shiploads of lead and zinc, and no inconsiderable quantity of gold and copper. Yet the Broken Hill mines are rarely

Main Shaft, Broken Hill Proprietary.

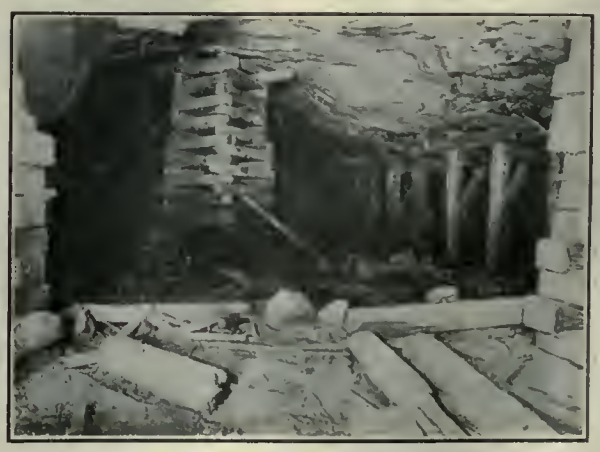
mentioned in the journals, and the average American, unless well informed, probably does not even know the name of the great silver-producing lode to which New South Wales owes its prosperity and the commanding position it occupies in the world's metal markets.

Like most of the world's great mines, those of Broken Hill were discovered by accident. In 1869, Charles Rasp left his home in Germany to seek his fortune in Australia. Apparently he did not find it quickly, for in 1884 he was only a 'boundary rider' (a bush-country euphemism for sheep-herder) killing time and strangling ambition on one of the dreariest stretches of saltbush and mulga-bush that even New South Wales afforded. The country round about had been prospected before, and was universally believed to be devoid of valuable minerals. Patrick Green, a storekeeper of Menindie, with a party of experienced miners and prospectors, had hunted for copper on the very spot where the city of Broken Hill now stands, but found nothing that looked good or afforded the slightest hope of something better deeper down in the earth. Then in 1883, Charles Nicholls went in search of whatever the fickle goddess of the mines might see fit to bestow, walked over the spot where now is located the main shaft of the mine that yields one-sixteenth of the world's annual output of silver, 'pegged a block,' and worked for a few weeks, finding nothing, and then gave up in disgust. He was willing to take a solemn oath to the effect that there was nothing worth digging for in that part of the saltbush country.

Whether Charles Rasp, the boundary rider, knew

Great Open-Cut, Broken Hill.

of these past failures or not does not matter. He noticed the peculiar appearance of the country that he traversed day after day. Odd-looking outcrops of 'ironstone' were distinguishable through the growth of saltbush that covered the half-desert; queer-shaped hills gave to certain sections an appearance that bordered upon the uncanny. It was after Broken Hill had grown into a great mining camp that the discovery was made that the despised ironstone was a rich sulphide ore. Although Rasp did not suspect that the ironstone was worth anything, he did think that so strange looking a coun-



Method of Timbering, Underground.

try must contain something of more value than the scanty desert vegetation that had grown, withered, and grown again for unealculated ages. He was not a geologist, nor even a mineralogist, and had not the remotest idea what that something might be. He made a wild guess that it might be tin. So he 'pegged a block' (for no one 'stakes a claim' in Australia), and sought for help to develop his problematical tin mine.

Rasp must have been a persuasive talker, for he

soon succeeded in getting together a syndicate, composed of himself and six other employees of the sheep ranch. That made seven members, constituting the syndicate, each one owning one share. The maximum assessment that could be levied was fixed at ten shillings per share per week, or a total of about $35 per week available for development work. Seven claims were located, and the parent of the Broken Hill Proprietary Mining Co., embarked in mine development, with less real working capital than would suffice to pay the office rent and postage bill of any up-to-the-minute American 'mining syndicate' trying to float a Nevada prospect showing 'free gold' or 'virgin silver' from 'the grass roots.'

It was not long until some of the future silver kings of New South Wales began to feel the weekly drain of ten shillings each upon their meagre wages. So they were compelled to sell fourteenth and even twenty-eighth interests in the mine. Sometimes 'the boys' were careless, when going to or returning from the mine, breaking down the fences and permitting the sheep to stray; and that got them into serious difficulties with the overseer, who would have regarded as a fool anyone who tried to tell him that the hole in the ground into which 'the boys' were sinking their money meant more for the future development of New South Wales than all the sheep in Australia were worth.

One day a boundary rider, named Philip Charley, who had purchased a fourteenth interest in the mine, went to camp in great excitement. "Look at that, boys," said he; "we're in luck at last." They looked at the specimens he exhibited, but couldn't see anything to get excited about; and one of them remarked, disgustedly, that it was "nothin' but bloomin' carbonate of iron." "No," said Charley, "don't you see the speeks of chloride?" That seemed to the 'boys' to be really funny. "Hold on to your share, Charley," said one; "you may make a thousand out of it." "I wouldn't sell out for that," the boundary rider replied. "Ho, ho," jeered another, "then if I hold on to mine a year or two I may make five thousand out of it." That was considered the wildest possible flight of the imagination. Yet within three years after that a fourteenth interest in that mine was worth, on the open market, more than fifty thousand pounds sterling. In ten years it was worth half a million pounds.

By 1884, it began to be apparent to everyone that there really was silver in paying quantities in the Broken Hill Barrier, and a little cluster of tents sprang up on the site of the future mining metropolis. One day a man from an older mining camp drifted that way and offered the members of the syndicate a dozen eggs for a monopoly of the restaurant privileges on their lease. Eggs were scarce, in fact almost unknown, in that part of the bush country, and the proposition was hungrily accepted. Thus was the commercial life of Broken Hill inaugurated, and the first business enterprise launched.

It was a bad beginning. Nine of the eggs proved to be hopeless, and the other three were open to grave suspicion, so that they were regarded 'only fit for custards.' Thus it happened that the municipality of Broken Hill, with a present population of 20,000, was hatched from a dozen stale eggs. In 1884, chlorides were discovered in large amounts, and then the boom began. In a few months there were 5000 people on the ground, notwithstanding the fact that the law regarded every individual as a trespasser. The land was all reserved from settlement and occupation. However, the Colonial Land Department had no desire to engage in wholesale prosecutions, and allowed matters to drift until late in 1887, when a proclamation was issued canceling the reserve and permitting settlement. Then came a fight for land. The occupants had no shadow of legal title, and every claim of any possible value was hotly disputed by a dozen or more contestants. Claim jumping, rioting, gun fighting, and assassination for a time made Broken Hill one of the wildest and most lawless of the world's mining camps.

This period of lawlessness is known in the history of New South Wales as the 'Battle of the Barriers.' As soon as it had been fought to a finish, the great Broken Hill mining boom rose to its highest pitch. It was just like all other mining booms—like the 'Kaffir circus' of Johannesburg, or the more recent Goldfield and Cobalt frenzies. Promoters traded upon the credulity of the people, rather than upon the riches of the mines—and the amount of credulity available passed human power of estimation. It was all converted into cash by the crafty. Everything within a radius of miles was 'pegged,' and shares in worthless saltbush claims were sold at figures that would have been regarded as fabulous for dividend-paying mines in old and well established districts. One man wanted badly to enter the gamble, but had not a one-pound note to his name. So he wired to a Melbourne broker to buy for his account 1000 shares in block No. 10, in which it was expected that the mineral lode would be cut at any minute. The broker had unlimited faith in anything bearing the Broken Hill label, so he executed the order, allotting the penniless speculator a thousand shares at the market price, which was then three pounds six shillings. In less than a week the lode was cut, proving to be of phenomenal richness, and shares soared to £20 each. The man with plenty of nerve, although with only enough cash to pay for a telegram, cleared £15,000 on the transaction.

In twenty-seven years, the little $35-a-week syndicate developed into the world's greatest silver-lead mining corporation, employing 6000 men in its mines at Broken Hill and its reduction works at Port Pirie; and the municipality hatched from a dozen stale eggs has become the wealthiest city of its size in Australia, the creator of a hundred colossal fortunes. Ten or twelve years ago, experienced mining men regarded the camp as rapidly declining, because the carbonate and oxidized ores that had been the making of the camp seemed to be verging toward exhaustion. Then it was found that down below the carbonate ores were sulphides extending to great depths, and that the 'ironstone' outcrop that scarred the face of the entire country round about was rich in silver, lead, and zinc. To extract the silver alone from the 'ironstone' did not pay; but to smelt the ore for the saving of the silver, lead, and zinc proved like rubbing the lamp of Aladdin.

As a result of the discovery of sulphide ores, and of practicable and economical methods of treating them, a railroad was built connecting Broken Hill with the ocean at Port Pirie, where one of the largest silver-lead reduction works in the world has been built. Pig lead is shipped to Europe literally by the shipload, and silver bullion by the ton. Most of the zinc concentrates are exported to Europe for treatment, but it is planned in the near future to build reduction works at Port Pirie for the treatment of these also. Small quantities of gold, copper, and tin are produced, and great expectations are entertained of the eventual finding of important tin-producing deposits somewhere in the neighborhood. Although the Broken Hill Proprietary is the greatest of the Barrier mines, with an output more than equal to that of all the others combined, still the Broken Hill Central, producing 1,500,000 oz. of silver annually, is something of a mine, too; and numerous others justify their existence by paying dividends with unfailing regularity. But when Broken Hill is spoken of, one's thoughts naturally revert to the Broken Hill Proprietary, which for years has held its position as the greatest silver producer in the world.

Gypsum produced in the United States as well as in foreign countries is mainly manufactured by grinding and partial or complete calcination into the various plasters, such as plaster of paris, stucco, cement plaster, flooring plaster, and hard-finish plaster. A steadily increasing quantity is being used as a retarder in portland cement. Refined grades of plaster are used in dental work, also as cement for plate glass during grinding, and as an ingredient in various patent cements. Considerable quantities are ground without burning and used as land plaster or fertilizer, while smaller quantities are used in the manufacture of paint, crayons, and paper, imitation meerschaum and ivory, and as an adulterant. The pure white massive form, known as alabaster, is much used by sculptors for interior ornamentation.

Sand-lime products may be put to numerous uses. It is claimed by the manufacturers that the bricks are suitable for use in superstructures and foundations and for all underground work, especially for sewers; that they improve with age, have great crushing strength, are low in porosity, are poor conductors of heat, and are unaffected by acids. It is also claimed that they are sanitary, and that they will not disintegrate under extreme climatic changes. On account of their uniform size, shape, and color it is said that they can be economically laid and can be made to produce a like face on both sides of an 8-in. wall. The bricks can be tinted any shade or color desired.

Some Surveying Problems

By E. R. Rice

A scheme that is quite useful in field work, and especially in stadia work where it is neeessary to sacrifice accuracy to speed, is shown in the sketches, Fig. 1. In the ideal case, shown at (1), where the instrument is set up at A and the rodman is at C, across a river or deep valley, too far to read the rod, the transit-man turns off an angle of 5° 42′ 30″ (theoretically 5° 42′ 38″), and lines the rodman in at B, at right angles to A C.

Then when the transit is moved to C, C B is measured either by tape or stadia, and A C = 10 C B. In ordinary country and ordinary work, it is sufficient for the rodman to guess at a right angle to A C. A right-angle prism can be used to advantage. Sometimes, as in (2), in sighting from one ridge to another, the rodman cannot go at right angles

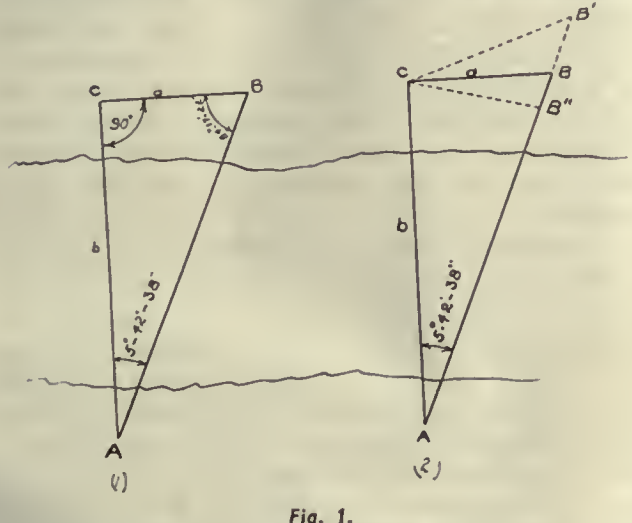

Fig. 1.

to C A, but has to walk along the right to C B′ or C B″.

When the transit is moved to C, then C B′ or C B″ is measured, the angle B C B′ or B C B″ measured, and C B solved for by $C B = \frac{C B' \sin C B' B}{\sin 84° 17' 22''}$. This method should be resorted to, also, when higher accuracy than is obtainable by the first method is desired.

I might mention here that the accuracy of stadia measurements, a solar attachment, and a 10-inch slide-rule graduated as close as a 20-inch, are all about the same, averaging in the neighborhood of 1:1000, and can be used in conjunction to advantage. The above formula can be solved at one setting of the slide-rule. In long stretches of country, A C can be made two miles or over, if the rodman has a field-glass with which to watch the transit-man's signals.

The sketches in Fig. 2 show three possible cases of the 'three-point problem', which may be solved in the following way:

$\eta = \Theta + \Phi$ in all three figures.

In (1), $\eta = C - A - B$

In (2), $\eta = 360° - A - B - C$

In (3), $\eta = 360° - A - B - C$

$\text{Cot } \Theta = \frac{a \sin B}{b \sin A \sin \eta} + \text{Cot } \eta$

The triangle U V W has all its sides and angles known, as would be the case in any triangulation system. S is any station occupied by the instrument, not on the circumference of a circle passing through the points U V W.

The instrument is set up at S, and the angles A and B read, and Θ solved for by the formula. With Θ known, we have a triangle S U V in which all the angles and one side are known, and hence the bearing and length of S U or S V can be found, and the total latitude and departure of the station S computed. This method is quite useful in a hilly country where triangulation stations are established on the tops of hills and one does not care to spend five or six hours tying in work by an ordinary traverse.

It is to be noted that in cases (1) and (3) it is impossible to place S on the circumference of a

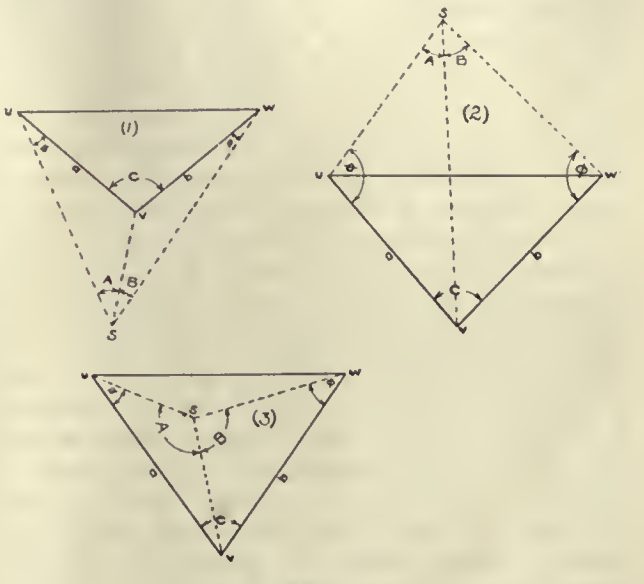

Fig. 2.

circle passing through U V W. Also, in solving case (2), attention has to be paid to signs, for when η is between 90° and 180° Cot η is negative, and when between 180° and 270° it is positive. It is therefore best to use case (1) or (3) whenever possible.

Carborundum is manufactured by fusing a mixture of pure granulated coke, very pure glass sand, and sawdust. The coke is the carbonaceous residue from the distillation of petroleum; the sand used is the purest glass sand. The sawdust is added mainly to make the mixture porous and thus to avoid explosions of the carbon monoxide produced during the reaction. The fundamental reaction takes place between the sand (silica) and the coke (carbon), resulting in the production of carbide of silicon, or carborundum. The carborundum crystals are crushed under manganese steel rollers in a circular pan of the same material. The crushed product is then treated in a bath of sulphuric acid to dissolve the minute particles of steel that have been cut from the rolls and the pan. This method of removing the steel has been found more satisfactory than the method of removing it by magnets. After the carborundum has been washed to free it from acid it is screened into different grades and is then ready for manufacture.

Tonopah Geology

By J. E. Spurr

***Conclusions in 1902.**—When I made my study of the mines of Tonopah, in the summer of 1902, I identified the highly altered and variable-appearing rock in which the principal veins were found as andesitic; and found that this rock was frequently covered by another andesite, later than the principal ore deposition, and therefore barren of ore and forming a 'cap-rock' to the ore-bearing veins. The formation which enclosed the veins I called the 'earlier andesite' (although my investigation shows the rock to be really a trachyte); the younger rock the 'later andesite.' Still younger than the 'later andesite' I found a variety of volcanic rocks, largely extrusive surface formations including tuffs, explosive breccias, and flows, but also partly intrusive. These younger rocks were chiefly rhyolitic in composition. One of the most conspicuous of these rhyolitic rocks was a rock with a glassy ground mass, usually packed full of angular inclusions of similar glassy rhyolite, so that the whole had usually the structure of a breccia. This rock occurred chiefly as surface flows in the district south of the town of Tonopah; to the north of the town, however, it was found to outcrop abundantly in the guise of an intrusive rock, younger than the 'later andesite.' To this rock the name 'Tonopah rhyolite-daeite' was given; it appeared to be plainly an autoclastic volcanic breccia. The origin seemed to be due to periods of quiescence and of partial congelations in a volcanic vent, alternating with periods of upward propulsion of the viscous lava, so that the hardened glassy exterior crusts were shattered and carried along in the upwelling still fluid portion of the same lava; and these incidents repeated a number of times produced the peculiar and characteristic structure of the finally solidified rock as we find it. Also later than the ores, and roughly contemporaneous with the Tonopah rhyolite-daeite eruptions and related intrusions (the span of the period of activity of this lava was considerable), I found a series of waterlaid tuffs formed in a lake of vast extent. Later than these tuffs, I found a number of volcanic necks, formed of distinct but closely related lavas of rhyolitic composition merging toward daeitic composition. In sum, it appeared that the productive veins had formed after the eruption of the 'earlier andesite' (which was and is still believed to be in a large measure at least a surface flow) and before the advent of the numerous other volcanic and volcanic-detrital mentioned. The whole volcanic history, including the formation of the ore deposits, was found to belong to the Tertiary, probably Miocene-Pliocene.

New Information Obtained in 1903.—Returning to Tonopah in the summer of 1903 for a brief examination of recent developments before the publication of my report, I found that a number of shafts had, after passing down through the 'earlier andesite,' penetrated, at a depth of a few hundred feet, a dense greenish glassy rock, highly altered, and essentially aphanitic, but evidently of rhyolitic nature. This rock is characterized by numerous angular light-colored or white inclusions, apparently of altered rhyolitic glass of much the same nature as the matrix, so that the whole rock appears to be an autoclastic glassy rhyolite. The most important veins seemed to be cut off by this rhyolite, whence it was concluded that the rhyolite was an intrusive sheet, younger than the 'earlier andesite' and the principal ore deposition; and this view, after recent exhaustive investigation, is still held. Since this rock was closely similar to the outcropping intrusive Tonopah rhyolite-daeite in the vicinity, it was correlated with this formation. This correlation has now been definitely abandoned, as subsequent extensive development work has proved this underground rhyolite to be of distinctly greater age than the Tonopah rhyolite-daeite (or Tonopah rhyolite, as it may be called with more simplicity and as much accuracy) and to outcrop at the surface nowhere in the surveyed and mapped district. Thus it constitutes a new formation, unexposed at the time of the original investigation. It is commonly referred to in Tonopah as the 'Upper rhyolite,' but will be here more conveniently designated as the West End rhyolite.

I observed, in the summer of 1903, that there was evidence of a second period of vein-formation, later than the extrusion of the West End rhyolite. The description of these later veins still holds. They are less definite and persistent than the veins of the first period, contain great quantities of low-grade or barren quartz, and the pay-ore, where it does occur, is spotty and usually of low grade.

The developments observed in the summer of 1903 also showed that several shafts had passed through the sheet of West End rhyolite into andesite, having apparently the general composition of the 'earlier andesite' above the sheet, and highly altered by hot-water action. No development work whatever had been done on the lower andesite body, but it was especially remarked that the alteration of this rock was entirely of the sort sometimes designated as 'propylitic,' that is, to calcite, chlorite, and pyrite, so that the rock took on a characteristic dark-green color; while the 'earlier andesite' above the West End rhyolite sheet was mainly altered to quartz, sericite, and adularia. Evidences of this propylitic alteration in this original 'earlier andesite' mass were, however, abundant in many places, so that this lower andesite was correlated with the 'earlier andesite,' although it was pointed out that this 'calcitic phase of the earlier andesite' was not associated with the ores.† At the time of this second examination in 1903 a vertical drill-hole downward from the bottom of the Mizpah shaft had penetrated a rock which I identified as rhyolite, and correlated it with the Tonopah rhyolite, and on this basis interpreted it as a barren formation, in which no pay-ore would be found. This correlation and interpretation have been confirmed by the recent exhaustive investiga-

*Abstract of report on the Geology of the Property of the Montana-Tonopah Mining Co., Tonopah, Nevada.

†Professional Paper No. 42, U. S. Geol. Surv., p. 32.

tion. In the Mizpah Extension shaft part of probably the same underground rhyolitic body was observed, and, as it still appears, correctly correlated. This deep-seated sheet became subsequently locally known as the 'lower rhyolite.'

Progress of Development Work and Modifications of Geological Views.—The extensive underground development of the succeeding years emphasized the distinction between the lower andesite body, or the 'calcitic phase of the earlier andesite,' and the upper or original 'earlier andesite' mass. The first-named rock, whose designation became usually locally abbreviated to 'calcite andesite,' was found to have a considerable lateral extent, with the general form of a sheet underlying the West End rhyolite sheet, and overlying the deeper Tonopah rhyolite (usually called locally the 'lower rhyolite') mass, which was also found to have considerable lateral extent. The green color, due to the type of alteration of the 'calcitic andesite,' was found to be quite uniform, and the scarcity of silicification or veins in this rock became increasingly apparent. Therefore there was an increasing tendency on the part of the local Tonopah geologists, who were watching the development, to question the correlation of the 'calcitic andesite' with the 'earlier andesite,' and this increasing doubt was shared by myself. These doubts took more definite form in my mind in the summer of 1908, when I returned to Tonopah for an examination of the West End and MacNamara mines. At that time I determined the fact that the West End rhyolite sheet could not be correlated with the Tonopah rhyolite, but was distinctly older. One of the strong arguments for the intrusive nature of the West End rhyolite sheet was therefore withdrawn, and a review of the whole argument became necessary, for if the rhyolite sheet were not intrusive, the main argument for the correlation of the underlying 'calcitic andesite' with the overlying original 'earlier andesite' was also withdrawn. The now more clearly exhibited (on account of new development work) uniform points of distinction between the two andesitic rocks led finally to the conclusion that the two andesitic sheets were indeed distinct and independent rock-formations. In this new light, a probable explanation appeared to be that the different formations were merely a series of regularly successive surface flows. This explanation was regarded with some favor, although it by no means explained the peculiar relations of the rocks to the mineral veins, as it still appeared that the most important veins in the 'earlier andesite' were cut off by the West End rhyolite sheet; and that the large but relatively low-grade veins of the second period, found in the West End rhyolite, did not penetrate the 'calcitic andesite' and, apparently, had not been found in the Tonopah rhyolite beneath.

In December 1909, the thesis that the different rock formations at Tonopah were a series of successive surface flows was brought out in a publication by J. A. Burgess, geologist for the Tonopah Mining Co. As a strong point in favor of this view, mention was made of the discovery, in the Mizpah mine and in the uppermost portion of the 'lower rhyolite,' of white dense banded rocks having the appearance of stratified tuffs, alternating with the coarser breccia such as is more common in this formation. Further specimens were found in cores obtained by deep drilling which could be easily interpreted, on account of their definitely banded character, as stratified. Microscopic examinations made by E. S. Larsen, of the Carnegie Institute, showed these rocks to have an essentially fragmental character, and this led to their designation as well-bedded tuffs. These considerations made the thesis that the rocks of the district were a series of successive surface formations, occurring in their normal order, with the oldest at the bottom and the youngest on top, a plausible one, which I had no difficulty in believing might prove to be correct.

Outline of Results of Recent Study.—In the early part of 1910 arrangements were made with the principal mining companies of Tonopah for a thorough geological investigation, to supplement my original report published by the Geological Survey, and to investigate the import of data subsequently exposed by development, with its bearing upon the future methods of development work in the camp. Accordingly I have spent a number of months in close detailed underground studies and mapping, and have already investigated in detail the mines of the Tonopah Mining Co., the Montana Tonopah, the Belmont, and the Midway, all adjacent and forming as a group a unit. The results of this arduous work have been finally to fix definitely and beyond doubt most of the geological relations. As is so often the case, it is the unexpected which has finally proved to be the true solution. The 'earlier andesite' still remains the oldest of the rocks, but turns out to be a true trachyte instead of an andesite, and will henceforth be called the Mizpah trachyte. In its lower portion it passes by transition into a dense banded glassy basal phase, called in this report the 'glassy trachyte.' This 'glassy trachyte' was at least several hundred feet thick, but where the exact base was, or on what older formation this flow rested, is not known. The West End rhyolite has been determined to be an intrusive sheet, mainly inserted along the zone between the 'glassy trachyte' and the Mizpah trachyte proper, although showing considerable irregularity. The 'calcitic andesite' is a distinctively intrusive sheet of considerable irregularity, younger than the West End rhyolite, and sometimes underlying this rock, directly, sometimes separated from this rock by a variable thickness of the 'glassy trachyte.' It appears to be of essentially the same age and composition as the 'later andesite,' is correlated with it, and is probably directly connected with the main later andesite mass, which appears to be essentially a surface flow. The 'lower rhyolite' is shown to be younger than the 'later andesite,' is correlated with the Tonopah rhyolite, as was done at the time of my original investigation, and is younger than the 'calcitic andesite' sheet, which it underlies and is locally known to intrude. This 'lower rhyolite' is evidently the flatly downward-pitching extension of the great mass of intrusive Tonopah rhyolite exposed on the surface

half a mile or so to the north of the main producing mines. The thickness of this Tonopah rhyolite is unknown, as it has never been bottomed; in the Mizpah mine a vertical thickness of over 1900 ft. has been demonstrated by drilling. Thus is demonstrated by the well-substantiated and extraordinary condition of a series of four successive sheet-like formations of distinct characteristics, of which the oldest lies at the surface, and the youngest at the bottom, and the whole order of superposition is the reverse of the order of age. This inversion, striking as it is, is not so regular as an elementary review of the situation indicates; the impression of great regularity arises from the limited field of development underground, which has a major horizontal axis hardly more than a mile in length, and from the fact that the geological conditions in this developed area are so complex that the area appears to the conception much more important in size than it actually is. Development carried outside of this limited area would doubtless show a great irregularity of relation; and, indeed, this is already exhibited on the borders of the developed area.

The veins have finally been divided into three groups according to their age, which groups correspond essentially with those originally made. The formation of the first group followed the advent of the Mizpah trachyte and preceded the advent of the West End rhyolite. This group comprises those rich veins which have made Tonopah famous. The second group followed the intrusion of the West End rhyolite, and preceded the advent of the later andesite (including in this term the 'calcitic andesite'). It includes frequently large veins, usually low grade or barren, and locally profitable. The third group followed the intrusion of the Tonopah rhyolite and comprises rare, essentially barren veins, never profitable.

Synopsis of Final General Results.—At Tonopah the oldest rock is a trachyte flow highly altered to quartz, sericite, and adularia. The lower part of this flow is a fine flow-banded glassy trachyte. The main body of the trachyte contains the oldest and by far the most important group of mineral veins; the glassy trachyte appears practically barren. Stresses subsequent to the trachytic extrusion produced horizontal faulting near the zone of transition between the main body of trachyte and its glassy lower portion; and along here a glassy trachy-alaskitic intrusion, very full of inclusions, took place. Subsequent movement reopened this line of weakness, and a second trachy-alaskitic intrusion came in—the West End rhyolite sheet. At a subsequent epoch came an eruption of andesite (Midway andesite), largely as a surface flow, but largely also as an intrusive sheet along the old zone of weakness, but typically below the West End rhyolite sheet; at a still later epoch there was a series of rhyolitic and alaskitic surface flows and intrusive mass called the Tonopah rhyolite.

The principal veins were formed after the trachyte eruption and before the Montana breccia-West End rhyolite intrusions. They are quartz veins carrying silver and gold. A second set of veins was formed after the West End rhyolite intrusion and before the Midway andesite eruption. This second set is divided into four successive groups—**A**, large typically barren quartz veins; **B**, tungsten-bearing veins; **C**, mixed quartz and adularia veins, typically barren; **D**, small productive veins like those of the first set, following the trachyte. A third set of veins was formed after the Tonopah rhyolite intrusion. They are quartz veins containing occasional lead, zinc, and copper sulphides. All of these veins formed at shallow depths, and the different types represent various stages of temperature. The first period veins represent the normal shallow-seated type, and followed the trachyte eruption: the second period **B** veins represent an abnormally intense shortly-sustained temperature, following the trachy-alaskitic intrusion; the second period **D** veins a directly subsequent briefly-sustained stage of temperature more normal to shallow depths; the third period a relatively high but briefly-sustained temperature, following the alaskitic (Tonopah rhyolite) intrusion. No vein-formation followed the andesite eruption.

The history of faulting is long and complex; important movements have taken place at every stage of the geologic history. These movements accompanied and were due to the volcanic paroxysms; and were so intense that locally the rocks are ground almost to a powder.

Before magnetic separation can be applied, it is necessary to free, or break apart by crushing, all the constituent minerals forming the crude ore. Theoretically the point to which comminution should be carried is that at which every particle of mineral is free to be attracted or rejected according to its permeability; this is, of course, the ideal situation, but can not be carried out in practice. Nevertheless, this theoretical point should be the aim. The practical rule is to carry the crushing far enough to free the maximum number of valuable mineral particles, having due regard to the cost of crushing, and the saving effected. There is no ironclad rule to be followed for the solution of this problem; the process, as a whole, requires an intimate co-relation of the crushing and separation factors. Different ores require widely different treatment; for one ore, moderately coarse crushing will suffice; for another, excessive pulverization is required to liberate the particles of magnetite, with the consequent added cost of comminution.

New abrasives recently placed on the market are aloxite, a product for steel grinding which is successfully used in machine-shops, as it does not heat the tool or draw the temper; samite, an abrasive for cutting aluminum which does not glaze or fill when used on aluminum or other fibrous metals; and carborundum fire sand, a chemical compound of carbon and silicon which is mixed with a binding material, silicate of soda, of 52° B., which is dissolved in water before being added to the fire sand. The mixture is made plastic and is molded to the interior of a furnace for a lining. It is understood that this lining will withstand very severe conditions.

The Panama Canal and Commerce

By E. M. Lawton

That the opening of the Panama Canal will bring the western coast of the American continent very much to the fore, is acknowledged by all, but the extent to which this great stretch of seaboard and contiguous territory will enter into the business markets of the world involves questions too large to answer, which have, indeed, not been fully appreciated by people in general. Probably the greatest development which can reasonably be expected from this new tide of commerce will be that of the mining industry.

Latin America offers the greatest possibilities, for already California, Oregon, Washington, and Alaska have demonstrated their resources and possible products, and the Pacific ports found in this stretch are destined to be the rivals of the greatest of the Eastern cities. But take a map of the two continents and contemplate the remaining stretch of country, and recall to mind what part the countries there shown have played in the world's history. Where is to be found a land of romance more brilliant and full of stories of pursuit of wealth? Such has been the lure of the stories of all ages surrounding Latin America that even today are abortive attempts by soldiers of fortune in Mexico and Central America to secure by adventure a portion of the wealth of these wonderful places.

Will the Canal separate the two continents? Physically it will, but at the same time will unite them by the stronger ties of commerce. Peru, Ecuador, and the west coast of Mexico will be thousands of miles nearer to New York. There are many persons in our own United States who do not know that Lima and Quito and the whole west coast of South America, lie to the east of the eastern shores of the United States. With the ship canal, vessels will sail south in almost a direct line from New York to Peru, or, if anything, to the east of south. The Panama Canal itself has its Pacific outlet, southeast of the Atlantic inlet. The merchandise destined for Buenos Aires can be transhipped at Valparaiso on the Pacific and still save twenty-five hundred miles of a detour in getting around the capes of Brazil. Much has been said of the probable influence of the Canal on commerce. It is safe to assume that the ten per cent of imports now supplied to South American countries by the United States will be materially increased. The development of the natural resources of the western coast will be so favored that great strides in advance may reasonably be expected.

Unquestionably the first of the countries to be largely influenced by the completion of the Canal will be Mexico. To the great mass of the Mexican people its southwestern coast is an unknown land, a most natural condition, because it is cut off from the east by the same chain of mountains that kept California practically unknown until the railroads conquered the Rockies. Already a coast-line railroad is built from the northern frontier for more than half the total distance to Tehuantepec, with the Pan-American also in operation from the Isthmus to the Guatemala frontier and beyond, while the gaps are rapidly being filled in. This is the result of the work of the latest times because financiers foresee the part this immense stretch of country will play in the new setting of the world's stage, with the Canal as the central figure. This is not the fever-laden coast which rumor would have it, but a veritable garden, whose climatic and agricultural character is but a continuation of the known salubriousness and fertility of southern California. Cane (sugar), cotton, tobacco, corn, pineapples, oranges, melons, onions, and like products are already grown

Position of Panama Canal.

on a mammoth scale; in brief, the combined possibilities of Texas and California are found all along the west coast of Mexico. And as for transportation, aside from the railroads building, Manzanillo has a deep-water harbor just completed at an approximate cost of ₱8,000,000, Salina Cruz, with unexcelled harbor and dock facilities, and with the Mexican Government planning to spend millions of pesos on harbor improvements in Mazatlan, the district shows preparation at every point for the expected increase of commerce which the Canal will bring.

There will also be opened to the world a wealth of minerals. There may come a time, and probably will, when the headwaters of the Amazon will develop the world's greatest placer ground, but in Mexico alone, it is easy to believe that the west slopes of the Sierra Madre will prove a treasure-house far exceeding the well known propheey of Cecil Rhodes.

It is much easier to describe the non-mineralized

sections of Mexico than those producing abundantly. Mining men, with years of experience in other parts of the world, after looking over Mexico, invariably make the statement that they have never seen such an abundance of mineral signs. From Sonora to the Isthmus, there are few districts which do not show evidences of gold, silver, lead, copper, zinc, iron, graphite, and saltpetre, in evidently paying quantities, with smaller amounts of asbestos, mercury, mica, and even rarer metals and precious and semi-precious stones. Beginning at the north and referring only to the western shores, the State of Sonora has already developed mineral resources in such districts as that of Cananea, besides which there are a half dozen well known districts now producing, despite the troubles which have existed until recently with the Yaquis. The State of Sinaloa is next to the south, and minerals are known to exist there, though the records of former times when the Jesuits were the miners, are not to be had, doubtless because they were not anxious for governmental espionage. The geographic position of this State as well as the territory of Tepic adjoining to the south, is such that they must needs wait for some such increased activity as the opening of the Canal will bring. They are wholly to the west of the mountain ranges and dependent entirely on the railroads now building and on ocean traffic, for the solution of the freight question. However, at least eight well defined districts are now developed in this section, waiting for the attention which capital is beginning to give.

The State of Jalisco, having but a small amount of coast line, and the rest well traversed by railroads, has already come into great prominence. There are many millions of foreign capital invested in this State, but the coast part is still undeveloped. In the State of Michoacan, in such districts as Tlalpujahua and Inguaran, the latter being the site of the famous copper mines belonging to the Rothschilds of Paris, there are many good prospects known. The State of Guerrero is perhaps the greatest in its mining possibilities. It is known as 'the land set on edge,' of box canyons and difficulties of transportation almost insurmountable. This is one of the largest States in the Republic, as well as one of the least populous. It is the sort of mineral country commonly known as 'a poor man's country,' although, until today, transportation and distrust of foreigners, in most of the wilder sections, has detracted from the value of the rich finds which hundreds of prospectors have made. The capitol of the State has no communication by railroad with the outside world. It is the centre of seismographic disturbances in the south end of the Republic, and in general the country has the reputation of being wild but rich in minerals and waiting for some general invasion of capital which will pacify the people, solve the transportation problem, and by 'community of interest' bring about the prophesied future.

Oaxaca has been called by President Diaz, the 'Pennsylvania of Mexico,' on account of the undeveloped iron and coal deposits which are found there, and reaching into Guerrero. The iron has been smelted for centuries, but not mined, simply taken off the surface. At one small charcoal furnace on the west coast of Oaxaca, which has been worked from almost pre-historic times, a grade of iron is manufactured which has been pronounced by iron experts to be equal to the best Norway iron, if not its superior. To furnace foundrymen, a visit to this little adobe furnace, turning out about 400 lb. of iron every 24 hours, would alone be worth the trip to Mexico in order to study the primitive methods employed. The State of Chiapas next to the Guatemala border and the peninsula of Lower California, are but little known as to their mineral possibilities, but without doubt these large territories, with a combined area more than half as large as California, entirely dependent on the development of the west coast, will furnish their proportionate quota to the interest which will be found manifested toward the great Canal and its attendant results.

MINING IN HONDURAS.

Mining claims may be taken by any person in Honduras, upon payment of the Government fees, foreigners having the same rights as citizens of that country. The mining laws are much like those of Mexico. Claims are 'denounced', which is equivalent to the American word 'located'. The discoverer goes to the proper Government agent, usually to be found in the nearest good-sized town, states where he wishes to prospect or mine, and at the stated time pays the fees, whatever they may be—never large—and goes to work. A claim may be taken to the extent of 1000 hectares, equivalent to 2470 acres (the maximum). Within six months the tract is surveyed by a Government engineer and the tax paid, which amounts to 50 cents silver per hectare. Of course, a smaller claim may be taken. The principal placer region is in the Department of Olancho, near the centre of the Republic. In that region are large areas of placer ground, cut by good-sized streams, among them the Guayape, Panal, and Jutiape. There are also gold placers south of Olancho and extending into Nicaragua. It is probable that these are on the same mineral belt which runs in a northwest-southeast direction through the Central American Republics. The climate of Honduras, in the Mountain region, is salubrious, even delightful, and one can live there in comfort; but that of the lowlands adjacent to the coast is hot, and malarial fevers are prevalent. Mosquitoes abound and transmit the various contagious diseases to which residents of the tropics are subject. For this reason those from northern climes should get away from the low coastal plains and into the highlands as quickly as possible. The real extent of the mineral resources of Honduras has never been adequately proved, because of the difficulties of transportation, there being but one short railroad, which runs a few miles into the interior from Puerto Cortez, in the northwest corner of the Republic. A gold dredge is at work near San Pedro, near the southern end of this railroad. There are no wagon-roads in the country, with the exception of one from the west coast of Tegucigalpa.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual its probable interest to the readers of this journal.

Weight and Volume of Ore

The Editor:

Sir—In your issue of February 18, in an article by L. S. Austin entitled 'Weight and Volume of Ore,' the writer gives, among other things, an account of a short practical method of determining the weight of ore per cubic foot as found in stopes, using wheat as a medium to give displacement of the ore in question. This method is, briefly, filling a box with ore and wheat and afterward filling the box with the same wheat without the ore, and thus determining the displacement or volume of the ore. It seems that a far better and quicker way would be to first weigh the ore, and have a tank or water-tight box handy with water to a known depth. Place the ore in the water and take a reading on the water after submersion of the ore; data is then available for calculating the volume of the ore. Unless the ore were extremely soluble, it would make no practical difference if the reading of the depth of water were taken quickly. At any rate, if a large quantity of ore were used (400 lb. being mentioned in Mr. Austin's article) it would have no practical effect on the determination if the reading of depth of water were taken immediately after submersion of the ore.

A. L. GERRY.

Hibbing, Michigan, March 8.

Re-location v. Resumption

The Editor:

Sir—In an editorial under the above headline which appeared in the *Mining and Scientific Press* of January 14, I find the following statement:

"The original locator having failed to comply with the law's requirements has forfeited his right and the claim is then open to location by any person willing to comply with the law, *except the original locator.*" (The italics are mine.) That may be true in California under the law of 1909, but to the best of my knowledge it is not true in any other Western mining State. It certainly is not in accordance with the practice in those States. Under the United States mining law, any claim that is forfeited by failure to do the required assessment work reverts to the Government and becomes a portion of the public domain. Under that law any citizen of the United States, of legal age, is competent to locate any vacant mineral lands on the public domain. In that law there is no bar, either expressed or implied, against any citizen. The prospector who has owned a claim and forfeited it has the same rights of re-location that any other citizen possesses. Absurd? Of course it is. And, so far as I am aware, California is the only mining State which has even attempted to wipe out that absurdity—and California has not been successful. The three-year penalty, to be effective, should begin with the date of the forfeiture instead of beginning with the date of the original location. If three or more years should elapse between the date of location and the date of forfeiture, is there anything in the California law to prevent the original owner from relocating his claim at once? The clause which pretends to do so seems to have been inserted merely to make business for the lawyer and trouble for the other fellow.

J. W. BUSH.

Lower Lake, California, February 12.

The Editor:

Sir—It is rather presumptious for one not a lawyer to doubt your exposition of the right to relocate a claim, in your editorial of January 14. There is no limit to the number of times a citizen, or one declaring himself as intending to become such, may locate vacant mining ground, and his own claim again becoming vacant mining ground, what is there in the Federal laws to prevent his again using his right on the same ground he had before? And doesn't the State law imply that he did have the right previous to its passage, and that he may again re-locate after three years? True, it may be the poorest kind of policy to permit this re-location, but an amendment of the Federal laws limiting a locator to some definite number of times he may use his right in any one camp, would seem to be about the surest way to stop this practice.

While writing you, another matter may be noticed. Just how are claim holders going to be compelled to record their proof of labor? The State law says, *shall*, etc., but provides no penalty for a failure to do so. Why not make it optional, as the Montana statutes do? As this question was thoroughly thrashed out in personal conversation with one of the assemblymen responsible for the passage of the bill, the point is mentioned more with a desire to call attention to the matter than for personal information. There is one matter that seems to be overlooked by most claim holders, particularly in California. A good share of the foothill country has been surveyed for many years, and much of it returned as 'barren and worthless,' 'bushy,' 'thinly timbered,' etc. Until there is an application for patent, the Land Office has no official knowledge that there is a mineral location. If now some one comes along and uses any one of the numerous filings other than mineral, after a short time of advertising, the title may pass to the later applicant, though the ground may in fact be mineral-bearing, providing the mineral claim holders do not see the advertisement and file a protest. A remedy for this would seem to be to have location notices made in duplicate, both sent to the county or district recorder, one to be returned to the locator, the other sent to the local Land Office to be there placed on file as an official record.

E. L. BALLOU.

Igo, California, February 25.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Heat has a tendency to demagnetize magnets, and a red heat will remove the magnetism completely.

Muntz metal is an alloy consisting of 3 parts of copper and 2 parts of zinc. Brass, as commonly made, contains 2 parts of copper to 1 of zinc.

Silver that contains lead that is to be treated by amalgamation should first be concentrated as thoroughly as possible to remove the lead, for the latter in any form is detrimental to amalgamation.

California oil is frequently used for fuel in generating oil. The duty usually is figured at 140 kilowatt hours per barrel of oil. At the Redondo plant, 250 kw. hr. per barrel was obtained, which earned a substantial bonus for the builders.

Electric power has been sold in California as low as 70 cents per hundred kilowatt hours. The cost of electric power is peculiarly subject to the influence of quantity, and prices necessarily and properly vary widely with the amount contracted to one user.

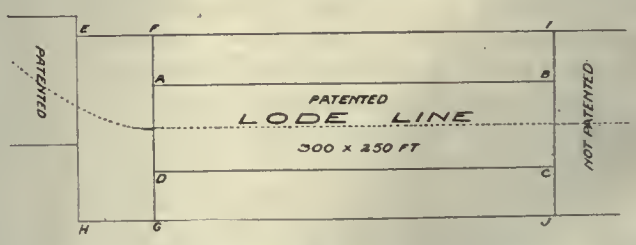
Sand when wet occupies about 10% more space than when dry, while broken rock does not change materially in volume when wet. Portland cement, when loose, occupies from 20 to 30% more space than when packed in barrels. A barrel weighs 376 to 380 lb. net, or 400 lb. gross, and occupies from 3 to 3.65 cu. ft. Four bags of portland cement go to a barrel, while natural cement takes 3 bags to a barrel. An average sand averages about 40% voids, while broken stone between the sizes of 1½ to 2½ in. contains about 54% voids.

Mantles for incandescent gas-lamps may be prepared as follows: Make a knitted or woven tube of cotton and soak in the following solution: lanthanum oxide, 30 parts; yttrium oxide, 20 parts; burnt magnesia, 50 parts; acetic acid, 50 parts; distilled water, 100 parts. To this solution 150 parts of water is added. When the mantle is first used the vegetable fibre burns off, leaving a skeleton of ash and salts. This will not stand rough handling or jarring. Another salt much used in the making of such mantles is thoria. The principal source of the oxides of thorium, cerium, and lanthanum is the mineral monazite. Monazite is chiefly obtained from Brazil, but about $150,000 worth of it was obtained from deposits in North and South Carolina in 1909.

Foaming in cyanide solutions is due to a variety of causes. In new mills particularly, oil may get into the alkaline solutions and form soap. High alkalinity, even in the absence of oil, is a common cause of foaming. Formation of calcium sulphate in the solutions is also given as a disturbing cause, and in certain instances the presence of copper and of lime compounds in the form of a fine powder seems to develop foaming. Probably the most common cause is the formation in the solutions of gelatinous hydrates, alumina being especially troublesome. The remedies to be applied are: (1) be sure no oil gets into the solutions; (2) reduce the alkalinity as much as possible; (3) clarify the solutions by use of a separate press. It must be confessed, however, that the whole matter is but imperfectly understood, and each case demands a special study.

Sulphuric acid was formerly manufactured by the chamber process. The acid so made was dilute, and where concentrated acid was desired it was necessary to evaporate. This was difficult, as the acid would attack ordinary metal, evaporating-pans of glass or porcelain were likely to break, and if made of platinum or gold were much too expensive. Recently the contact process has been devised whereby SO_2 and air are made to pass over heated platinized asbestos; the SO_3 thus formed is caused to unite with any desired quantity of water, and so acid of any desired strength can be made. A further advantage of the contact process is that it can be installed on a comparatively small scale; a single unit for burning 8000 lb. of pyrite per day, yielding 8000 lb. of H_2SO_4 may be erected for about $40,000. One of the most important points in the manufacture of H_2SO_4 is to be certain that the pyrite used is free from arsenic and other volatile metals.

Where a lode location *E H J I* is made so as to embrace a narrower patented lode location *A B C D*, which patented claim includes within its surface boundaries the apex of the lode for the entire length of the patented claim, and thus leaving on either side of the patented claim two long, narrow strips of ground, *A B I F* and *C D G J*, without any apex of any vein in either of these strips, it is extremely doubtful whether these strips can lawfully be held as a part of the larger junior location. As



a rule, a lode location should be predicated on a lode, and surface ground extending beyond the lode, where it is apparent that nothing but non-mineral surface ground is sought to be obtained, will hardly be recognized as a valid appropriation of such surface territory within the intent of the statute. Of course, junior locators are permitted to extend the lines of their locations over on patented senior claims in order to parallel end-lines and secure more complete extralateral rights, but this privilege has never been extended to a case where the junior locator's intention is palpably only to secure additional surface territory beyond the linear extent of free apex existing within the junior claim. Without doubt, the junior location would be valid as far as the parallelogram *E F G H* is concerned.

EL ORO MINING & RAILWAY COMPANY

The report of this company for March shows that the mill ran for 29 days and crushed 28,910 tons of ore, yielding bullion worth $207,410, at a total working cost of $129,050 ($19,850 being developed), with a resulting profit of $78,360. The railway yielded a further profit of $9000.

TIN PRODUCTION, STRAITS SETTLEMENT

The world's production of tin for 1910 was about 100,000 tons, and the average price was £155 5s. 3d., approximately $753 per ton. The mines of the Federated Malay States of the Malay Peninsula are the chief source of supply. *In Tinland*, a weekly journal, published at Kuala Lumpur, gives the following figures showing the output of tin for eleven months of 1910 of the several States: Perak, 387,931 piculs; Selangor, 218,922; N. Sembilan, 32,105; Pahang, 37,030; making a total of 675,989 piculs, equivalent to 44,953 tons. This represents the products of about forty mines. The smelting works at which the ore is treated are situated at Singapore and Penang, and these are in control of Europeans. The United States consumes over 35% of the world's output of metallic tin.

THE LENA GOLD INDUSTRIAL COMPANY

The report of the Lena Gold Industrial Co. for the fiscal year ended October 14, 1910, as published in the *Irkutsk Daily Sibir* of February 15, 1911, gives the following interesting facts: The property includes 43 placers of an average area of 250 acres each. The record of operations shows the handling of 0.38 cu. yd. of gravel per man per shift, the working of 1,884,710 shifts, and an aggregate of 724,573 cu. yd. of gravel washed during the year. The recovery of gold resulting from the company's own work amounted to 765.6 poods, equivalent to 403,195.6 base ounces troy; there was recovered by tributers, 18.4 poods, or 9690.2 base ounces; gold purchased, for the most part paid for in trade, 33 poods, or 17,379.1 base ounces, making a total of gold delivered to the Government assay officer at Irkutsk of 817 poods, or 430,264.9 base ounces troy. While the average value of the gold is not given, it is commonly reported at $17.75 per ounce, or $9360 per pood. Taking this average as a basis, the season's output of gold, including the small amount purchased, amounted to $7,637,200; and the average tenor recovered from 724,573 cu. yd. of material mined and sluiced was $9.87 per cubic yard. The cost per cubic yard is not given, but it has been sufficiently commented on in the reports of the Lena Goldfields Ltd., which holds the bulk of the shares. The low duty per man, less than $^2/_5$ of a cubic yard per shift, goes far toward accounting for the excessive cost known to have been incurred. The mines are situated near Chita, East Siberia.

TRANSVAAL MINERAL PRODUCTION

The total mineral output of the Transvaal for the month of January is returned by the Mines Department as of the value of £2,892,217, an increase of £17,986, as compared with the previous month. This total does not include diamonds, otherwise the total value of the mineral output would just about reach three millions sterling in value. Gold, of course, accounts for the largest portions of the output, which was valued at £2,753,543, of which no less than £2,647,808 was contributed by the Rand alone. The value of the diamond output may be estimated at £110,000. Despite the growing use of electricity at the gold mines on the Rand the tonnage of coal sold by the Transvaal collieries increased to 339,162 tons, but the average price realized at the collieries was only 4s. 10d. per ton, as against 4s. 11d. per ton in the month of December. Perhaps February may see a further decline in the average selling price of coal, as several low-priced contracts started upon that date. The total labor employed in the mining industry of the Transvaal was 27,190 Europeans and 215,867 negroes in December, but in January it had increased to 27,382 Europeans and 220,365 negroes. There were 105 fatal accidents in January, 15 Europeans and 90 negroes, as compared with 78 in the month of December.

The gold output of the Transvaal for February has been declared at 610,828 oz. of fine gold, in value £2,594,634. In comparison with the previous month the decrease amounts to 30,119 oz. or £170,752. The output of the Witwatersrand was worth £2,488,589, and that of the outlying districts £106,045. The stamps at work numbered 9627 and the tube-mills 201. On the Witwatersrand 9080 stamps were in operation. The February return is really better in point of production and profit than were the results obtained in January, if the statistics for both months are analyzed on the daily basis. On this basis there should be a shortage of £257,259 in the Rand production alone, whereas in reality it is less than £170,000. The profit should be £81,627 less, whereas actually there is only a decrease of £51,859. The following were the principal producers on the Witwatersrand:

	Stamps at work.	Tube-mills at work.	Output.
East Rand Proprietary	820	25	£228,103
Crown Mines	620	19	202,120
Randfontein S.	400	11	125,168
Robinson	250	6	111,639
Geldenhuis Deep	420	7	89,317
Simmer & Jack	320	6	86,237

INSPIRATION COPPER COMPANY

The report of Henry Krumb, consulting engineer for the Inspiration Copper Co., dated February 20, has recently been made public. Mr. Krumb describes the ore as occurring in small seams and veinlets, and also as minute grains of copper minerals, disseminated throughout a gangue consisting generally of silicified schist, but also, occasionally of granite porphyry. It was formed by secondary enrichment, through leaching and re-deposition at a lower horizon, of the primary copper contents of the mineral belt. The leached capping averages 367 ft. in depth. It lies above the enriched sulphide zone which forms the commercial orebody and which averages 155.5 ft. in thickness. This orebody has been developed by drill-holes and underground workings for a length of 3400 ft. and a maximum width of 1400 ft. As in previous reports, the ore reserves have been divided into two classes, namely 'developed' and 'partly developed.' Ore is considered as developed when bounded by either drill-holes or underground workings not in excess of 200 ft. apart. In blocks with drill-holes more than 200 ft. apart the ore has been classed as partly developed; but no ore has been allowed where the drill-holes were more than 400 ft. apart, nor has any ore been allowed beyond the lines connecting either drill-holes or underground workings. Values have been calculated for each block by averaging all samples taken within the block in proportion to the length of drift or drill-hole represented by the samples. On February 15, 1911, he estimated that there were developed 17,173,000 tons of ore, assaying 2.02% copper, and 4,029,000 tons of ore assaying 1.90% copper, making a total of 21,202,000 tons, averaging 2% copper. The above ore is all developed on 39.8 acres out of a total of 581 acres owned by the company. The number of tons of ore per acre, developed and partly developed, is 543,000 tons. To date 81 holes, with a total footage of 45,433 ft., have been drilled, and underground development work aggregating 27,526 ft. has been done. A small experimental mill has been erected, in which tests are being conducted to determine the method of concentration which will give the best results on ore, and also the kind of machines to be selected for the purpose. Tests so far conducted have given satisfactory results, and when they are completed the design of a mill to treat 5000 tons of ore per day will be commenced. To this W. B. Thompson, president, adds that a telegram from the manager, T. R. Drummond, states that on March 1 the ore reserves had been increased to 18,738,000 tons of developed, and 3,490,000 tons of partly developed ore.

Special Correspondence

BUTTE, MONTANA

Mr. Thayer's Report. — Reconstruction at Great Falls. — Centrifugal Separator.—Excellent Conditions of Mines.—Retimbering Mines. —High Ore Mine.—Probable Increase of Output.

Benjamin B. Thayer, president of the Anaconda Copper Mining Co., has completed his inspection of the properties of the company and returned to New York. Previous to his departure he stated that he had found all mines and smelters in fine condition. In regard to the numerous reports touching extensive improvements to the smelters at Anaconda and Great Falls, Mr. Thayer says that they are without foundation. No new work was being done at the Great Falls plant, and none was in contemplation. A short time ago Hancock jigs were tested and they had been found so satisfactory that they have been substituted for the others in use. The Hancock jigs have greatly increased the capacity of the concentrator.

Some reports sent out in the past few weeks would make it appear that the Washoe smelter at Anaconda was going to undergo very extensive improvements and that it would be necessary to close down the plant for a time. Mr. Thayer said that nothing of the kind is under consideration. "We are always carrying on certain tests in an effort to improve methods, but there is no reason whatever why the smelter should be closed down in consequence or any further curtailment made in the output." Mr. Thayer added that the tests being conducted at present had to do with improved methods of concentration. A new system of centrifugal concentration is being tested and may lead to a revolution of ore concentration. A machine with a capacity of 250 tons of material per day has been made and is soon to be shipped from New York to the Washoe smelter. It is expected that within 90 days it will be demonstrated whether the new system is a success. On test runs in the East the machine is said to have worked perfectly. The method of concentration by this machine is to throw the material out from the centre, separating the different particles and casting the heavy ones farther off. The system is entirely new, and has not been tested elsewhere.

In talking about this new machine, Mr. Thayer said that this was only one of many things the Anaconda company was constantly testing and experimenting with in order to keep ahead of the times and avail itself of the best machinery and methods. He said that another important test that is being carried on now at the Washoe is in sizing ores. Asked about the condition of the mines, Mr. Thayer replied that they never looked so good as at the present time. "The most gratifying thing to me," he said, "is the condition of the Anaconda mines at depth. Every new level that is being opened seems to be better than the one above." He added that the company intends to maintain the present output until there is a general improvement in business conditions. "Improvements tending toward reduction in costs are being made in all departments and it is only a question of a month or more until a number of the large hoists on the hill will be operated by compressed air generated by electricity at the new power plant at the High Ore mine. I do not think that there has ever been a year in the history of the company's mines when as much ore has been developed and the ore was of such an excellent grade."

Mr. Thayer said that in his opinion business conditions would improve when the Supreme Court decisions were all disposed of and the Canadian reciprocity question settled. He said that just as soon as conditions warranted it the Butte mines could nearly double the present output. During the curtailment period advantage has been taken to do a lot of re-timbering and other work. The work of re-timbering the St. Lawrence shaft is about completed and operations will be resumed in part just as soon as the work is completed. The re-timbering of the Anaconda mine will take several months more. In the mines formerly owned by the Boston & Montana company, the Butte & Boston, the Washoe, and Butte Coalition, conditions are better than they have been for some years, and the ordinary amount of development work is being kept up. He said that in the High Ore mine where the fire made its appearance some time ago, there was not a sign of gas and all appearance of the fire had disappeared, but for the purpose of making sure that all danger was passed, the mine would not be operated for some time yet.

CORDOVA, ALASKA

Opening of Copper River & N. W. R.R. — First Shipment of Copper Ore.—Lower Freight Rates.—Chicken Creek. —Opening of Nome Route.—Heavy Rush of Prospectors.

Saturday, April 8, 1911, was 'Copper Day' at Cordova. Early in the morning, to the accompaniment of every bell and steam whistle within a mile of Cordova, the first freight train on the Copper River & Northwestern railway loaded with 1100 tons of high-grade copper ore from the Bonanza mine, pulled through town. The Chambers of Commerce of Seattle and Tacoma were prepared to receive the shipment on Friday morning, April 14, with an appropriate celebration commemorative of the opening of Alaska's first through trunk line and the initial shipment of this remarkably rich copper ore from the interior.

The Copper River & Northwestern railway has now been turned over to the company by the contractors, and regular train service has been inaugurated between Cordova, the seaport, and Kennicott, 197 miles into the interior. Coincident with the opening of the railway, its officials have voluntarily reduced the rates on ore and concentrate from all points on the railroad to the smelter at Tacoma. In line with the plan adopted by Western railroads, this new tariff is based upon the value of the ore, so that the smaller shipper, the owner of low-grade ores, and the prospector who is trying to develop the country, gets the advantage of the lowest rates. The rates run from $5.75 per ton on the lowest grade ore to $33.70 per ton on ore which shows high value. The announcement being publicly made on the day of the opening of the railroad, created most favorable comment, as it indicates the determined effort of the railroad company to develop the interior of Alaska, in giving to the small shipper every opportunity and advantage in prospecting and developing. It is also acting as an incentive to prospectors to go into the country. The rates quoted include railroad transportation to Cordova, wharfage and handling at Cordova, and steamship transportation to the Tacoma smelter.

Word has just been received of a disastrous fire which destroyed a large portion of the business district of Iditarod on Sunday, April 9. The loss has been estimated at $75,000. This place is the centre of activity for the Iditarod district, which promises to be one of the good producers during the year. Chicken creek, in the Iditarod district, is coming to the front and prospecting carried on throughout the winter has demonstrated it to be as rich as the famous Flat creek. Several finds are reported from this district.

The competing steamship lines have announced the opening of the Nome route, commencing June 4, and continuing through the summer. This will be the signal for one of the heaviest movements to the Northland known since the early days of Nome, owing to the remarkably rich discoveries made last year at Squirrel River, Kuskokwim, Iditarod, and other points which are reached from the Nome route. As usual, the stampeders have been rushing into the country weeks ahead of time, and as a result Valdez, Seward, and Cordova have been filled with men for the last month. They have gained nothing at all by rushing into the country so early, as it has been impossible to leave the towns owing to the fact that the country has been covered with snow. But now, and until well into June, is the time to leave for the North. The service is regularly maintained to southeastern and southwestern Alaska, while the route to Nome, Kuskokwim, and Iditarod will not be opened until June.

TORONTO, CANADA

Decline of Porcupine Boom. — Hollinger Milling Plans. — Progress Notes of the District.—Diamonds at Tulameen.—Temiskaming & Northern Railway.—Keekeek Goldfield.

The Porcupine boom on the stock market is experiencing a decided reaction, Hollinger, the leading stock, having dropped, accompanied by a depression of the whole list of lower-priced issues. Investment in these has been mainly speculative, as is clearly shown by the rush to take profits whenever an advance of a few points is made. In view of this tendency it is hardly likely that any very decided or permanent upward movement will occur, at least until a dividend-paying era sets in and convinces the public that some of the mines have a substantial basis. Despite the professions of the Government of its anxiety to protect the public from the snares of the wild-cat promoter, it does not seem to be anybody's business to enforce the stringent legislation relative to advertising and prospectuses, which is little regarded in some of the announcements now being made.

The Hollinger has modified its plans for milling ore. It is said that the 30-stamp custom mill, to be controlled by the Timmins-McMartin-Dunlap syndicate, is to be supplemented by a cyanide plant supplied by the Merrill Metallurgical Co. of San Francisco. Tube-mills probably will be introduced to supplement the work of the stamps, but exact details have not yet been settled. A diamond-drill is being installed to test the orebody in depth. On the Standard a boiler and hoist have been installed, and two shafts are down over 40 ft. A rich find of free gold has been made at the bottom of one shaft. The Foley-O'Brien mine, in which high-grade ore was recently struck at 68 ft., and driving has been carried on with good results, has passed into the hands of a newly organized company known as the Foley-O'Brien. Operations are in charge of Mowry Bates, an experienced mining man. A vein recently struck on the Crown Chartered in the drift at the 50-ft. level, has proved to be 3 ft. in width and carries an average of $32 per ton. At the Vipond a 30-hp. boiler has been put in to operate a 2-drill compressor plant. One shaft is down 100 ft. with a crosscut 46 ft. to the vein, which is yielding good ore. The Callinan claim, adjoining the West Dome, has been sold to American capitalists for a figure stated at $225,000. The two Shillington-Richardson claims, north of the Armstrong-McGibbon holdings at the east end of Pearl lake, have been taken over by the Porcupine Gold Trust for $150,000, and a force of 20 men has been put to work on the property. A syndicate, headed by S. R. Clark, has secured the properties of the Success Gold Mines, consisting of four Tisdale claims, adjoining a portion of the Bewick-Moreing holding on the north. The new company will be capitalized at $2,000,000.

The mining industry of Cobalt is still languishing on account of the shortage of power, and shipments have greatly decreased, those for March being only 1819 tons as compared with 2516 tons for last March. The Right of Way, as was generally anticipated, has passed its dividend. The list of dividend-payers has been increased by the addition of the Beaver, which has declared an interim dividend of 2½%. The Beaver has good ore on the 200, 250, and 300-ft. levels. The new vein on the 300-ft. level is 8 in. wide and carries 2900 oz. per ton. The Eric Cobalt Co. which has liabilities of $33,000, is being wound up. The Nova Scotia's statement of profit and loss as of October 31 shows a deficit of $64,268 for the year and a total deficit of $235,-064. Later operations have been more profitable, shipments of bullion up to March 1 yielding a net profit of about $38,000. The Wettlaufer of South Lorrain has been transferred to the Mines Finance Co. of America. The Ophir Cobalt has struck rich ore on the 100-ft. level.

The news of the finding of diamonds in the Tulameen district, British Columbia, has awakened considerable interest, and the Canadian Geological Survey has received numerous enquiries concerning it. Some prospectors have gone to the district, though Charles Camsell of the Survey states that it will be impossible to stake claims for some time on account of the depth of snow. He will re-visit the area during the summer and make further investigations.

The Ontario Government declines at present to extend the Temiskaming & Northern railway to Gowganda. They will, however, grant a charter to any private corporation that is prepared to undertake the enterprise. There is a rush of prospectors to a new goldfield, known as Keekeek, situated in Quebec province some 60 miles northeast of Haileybury, where some 6000 claims have been recorded. The area is about 20 miles wide, extending from Lake Opasatika to Lake Missinable. The Quebec mining regulations are very favorable to prospectors.

JOHANNESBURG, TRANSVAAL

Enforcement of Mining Regulations.—Round v. Rectangular Shafts.—Natal Coal Mines.—Arbuckle Process. — Decrease in Grade. — Klerksdorp Strike.

A question of some importance to mine managers on the Rand is dealt with in the Government Mining Engineer's annual report, namely, that of making the manager directly responsible for carrying out the mining regulations instead of as in the past leaving that duty entirely in the hands of the mines inspectors. There are few mining fields in the world where such an excellent set of mining regulations exists as that in the Transvaal, but probably there is no other mining field in the world where they are broken with so much impunity, especially on the part of the employed. The regulations with regard to

Map of South Africa.

the laying of dust so as to reduce the risk of miners' phthisis to a minimum are generally disregarded by the men for whose benefit they are drawn up, and when the workmen will not take the necessary steps for the preservation of their health it is easy to understand that those regulations framed for the prevention of accidents and the men's personal safety are broken to a much larger extent. The explanation is that hitherto the mine officials have not been held responsible for the due observance of regulations in and about the mines, but that duty has devolved upon the inspector, who manifestly cannot be always in the mine, and whose occasional presence is announced all over the mine within a short time after his arrival. It would clearly require an army of inspectors to enforce the regulations under these circumstances, and the wonder is that the mine manager was not called upon to see that the regulations were properly enforced when they were first brought into use many years ago. In England a mine manager finds it necessary to prosecute all offenders against the regulations, and to send in a report of every such prosecution to the mines inspector for his own protection.

The old controversy regarding the best shape of shafts suited to the requirements of the Rand has been revived by the sinking of a circular shaft at the New Modderfon-

tein mines. With the exception of a few circular shafts, put down by Laurie Hamilton many years ago, all the shafts at the gold mines are rectangular in shape, but at the present time, when shafts are being sunk through the dolomite formation, carrying large feeders of water, the advisability of sinking them circular in shape is being seriously considered, as that shape admits of the water being shut out by iron or steel segments and pumping is thus lessened. At the Western Rand Estates beyond Randfontein, circular shafts are being sunk through the dolomite, and the water shut out permanently; this being the first instance where work of this kind has been taken in hand at the gold mines on the Rand. Had circular shafts been sunk at Grootvlei the shafts would never have been stopped through inability to deal with the water, and the Springs mines, had they adopted circular shafts, would also have made better progress where it is announced they have only just succeeded in passing through the dolomite. Probably at the New Modderfontein mine the same reasons for using a circular shaft do not apply, but the consulting engineer, having been trained at collieries in South Wales where circular shafts prevail, it is easy to understand why preference should be given to that cross-section. The Witwatersrand goldfields, as the mines increase in depth, are more approaching coal-mining conditions than metalliferous mines in other parts of the world. The need for good ventilation in the deep mines of the Rand is also becoming as well recognized as in a coal mine. The greater area of a circular shaft as compared with a similar rectangular shaft would also conduce to less interference with the air currents and make for better ventilation all around. The best shape of shafts to adopt must naturally depend upon the conditions, and on the Rand no hard and fast rule can be laid down, as circumstances may exist making either circular or rectangular shafts almost imperative.

The prospects of the Natal coal trade are causing some uneasiness to shareholders as owing to increasing competition, shortage of railway stock, loss of Cape railways locomotive contract, and the stoppage by the Indian Government of further recruiting of laborers for the Union of South Africa, there seems to be quite a crop of troubles ahead. Last year's output of coal in Natal was 2,296,447 tons as compared with 1,786,568 tons in 1909; a record output, but it seems doubtful at present whether this year's will be as satisfactory. The first month of the year has resulted in an output of 191,661 tons, of which 100,024 tons was disposed of for bunkering purposes and 31,055 tons was exported, but, seeing that the railway has refused to lower the railway rate on carriage of export coal, the question of bidding for the contract on the Indian railways has been considered and found impracticable. There will therefore be nothing to make up for the loss of the Cape railway contract; one colliery has already closed down, and it is not at all unlikely that before the year is out others may feel compelled to take a similar step.

At the East Rand Proprietary Mines, after somewhat lengthened tests, it has been decided to abandon the Arbuckle process of treatment of sand and slime; it is said that a Butters vacuum system may be installed. At Benoni the Arbuckle method of treatment, with some slight modifications, is being adopted and the results will be awaited with some interest.

Despite all that has been said lately about keeping up the grade on the Rand, the average recovery, according to the Chamber of Mines returns for the month of January, was 28s. per ton as compared with 28s. 1d. for the previous month. The decline is not much, but it follows a continued decline for many months and accompanies a rise in the working costs of from 17s. 9d. in December to 17s. 11d. in January, so that altogether the profits per ton are about three pence less. For the month of January the tonnage milled was 1,855,232 tons as against 1,827,423 tons in December, so that the lessened profits per ton were not due to a smaller tonnage being handled. Moreover, in spite of the increased tonnage treated, the working profit for January was only £954,536, being £22,406 less than during December when a smaller tonnage was treated. There can be no doubt that this continued fall in grade is due to the exhaustion of some of the richer rock near the outcrop and the milling of increased quantities of deep-level ore of lower grade than formerly. Taken in view of other indications, it raises a very interesting question regarding the future of some of the deep-level mines, particularly where they are of unusually low grade. One of these, the Simmer & Jack East, is said to be looking better in its lower levels and it is to be hoped that a corresponding change for the better will soon be seen among its neighbors.

The rich Cyferfontein bore-hole strike of 39 dwt. over twelve inches has been confirmed in another bore-hole about three miles farther to the southeast, the reef having been struck by the drill after passing through troublesome ground. The core looks well and should the results turn out anything like those in the first hole, Klerksdorp should do well again, while the possibilities of that section of the Rand beyond Randfontein so long dead will re-command attention.

DOUGLAS, ARIZONA

Electric Transmission Line From Douglas to El Tigre. — Information Concerning the El Tigre Mine.—Notes on Cochise County Properties.

The transmission line which will carry electricity generated at the Copper Queen smelter power-plant at Douglas, Arizona, to the Lucky Tiger Gold Mining Co.'s camp at El Tigre, Sonora, will be completed and ready for operation by April 15, and for the first time in the history of the border electricity generated on the American side of the international line will be used in the operation of machinery at a Mexican mining camp. The power will be used to operate the stamp-mill, new cyanide plant, and hoisting machinery at the El Tigre mine and to light the camp. The route of the transmission line is from the smelter over the international line to a point a little south of Frontera, 55 kilometres south of Douglas; thence over the mountains to the El Tigre stage line, with which it connects at a point six miles east of Yzabal, the El Tigre shipping station on the Nacozari railroad; thence along the stage road to the camp, a total distance of 65 miles. A telephone line has been strung on the poles carrying the heavier transmission wires. The latter are of No. 4 copper, single circuit, three-phase, 60-cycle, carrying 45,000 volts. The poles are of Texas pine, treated by the Burnettized system, with creosoted butts. This treatment not only preserves the wood against the elements, but also saves it from the borings of woodpeckers and other fowls that are pleased to make nests in the poles.

To supply the power for the El Tigre camp the Copper Queen smelter has installed two new 750-kw., General Electric, low-pressure turbine generators, generating at 2200 volts. These have been placed in the west end of the big power plant, and will transmit the equivalent of about 900 horse-power. A concession was granted by the Mexican Government for the route of the transmission line, and also for the passage of the electric power from the American side to Mexico. The power will be used for all purposes at the El Tigre camp. The Lucky Tiger mine has become one of the most notable silver mines in the world. Just why it lay so long undenounced while at the same time so close to the American boundary is one of the mysteries of Sonora. For years the Indians and Mexicans had spoken of a wonderful lode of silver ore rising from the mountain tops to the south of where Douglas is situated. Many prospectors searched for this vein, and finally, when the Cinco de Mayo mine was discovered, only six miles north of the El Tigre, it was thought that the bonanza long heralded had been found. When A. J. King, in partnership with the owner of the Cinco de Mayo, Francisco Garcia, took from the Cinco de Mayo $680,000 worth of silver ore in fourteen months this impression grew to conviction. Then came James Taylor and his dog Tige of Douglas. The dog is given credit for discovering the mine, at least to the extent that it was named The Lucky Tiger. Follow-

ing big development and the shipment of high-grade ore and concentrate valued at millions, out of which the company has paid to date over $1,000,000 gold in dividends, the company decided upon an increase of production. While working the high-grade gold and silver ores enough low-grade ore, averaging $30 per ton, had been uncovered to run the new cyanide plant for five years. The cyanide plant will have a capacity of 250 tons per day. The Pachuca tank system formed a part of the improvements. Instead of zinc shavings the Merrill system of zinc-dust precipitation will be used, with the Kelly filtration presses. The stamp-mill capacity will be doubled, and the heaviest stamps made have been installed, together with rolls. Engineers who have recently examined the El Tigre property declare that the mine has blocked out and partly stoped the largest tonnage of low-grade silver and gold ore ever uncovered in any silver mine. The main El Tigre vein has been developed for many thousands of feet, and the company has also opened up much high-grade ore on what is termed the Sooy and the Seitz veins. The Lucky Tiger Mining Co. is owned by Kansas City capitalists, who purchased the property for $350,000. The capital stock is now $8,000,000, and the report for 1910 showed that the mine had produced $927,000 worth of gold and silver. J. W. Malcolmson, as consulting engineer, has charge of the property.

The Arizona United has a Standard drilling rig, capable of reaching 1000-ft. depth. E. W. Walters is manager of the property, J. M. Libbey superintendent. They are making 20 to 30 ft. per day, which is good work in the hard dolomite. The sludge does not yet show many signs of copper, but this was not expected at less than 300 ft. The work is being done at the lowest point on the property, and below where a large amount of surface ore was taken out during the time the smelter was operating; thus making it possible to cut with the drill the contact in which the ore was found at a depth of about 300 ft. There is here a 400-ft. incline, from which a large tonnage of ore was taken, but which is now filled with water. A good body of sulphide ore was found in this incline, and it is believed a larger body of sulphide occurs at greater depth, and to open it would supply the character of ore required to operate the smelter. There are on this property a number of houses for workmen, office buildings, and a fine hoisting plant. The smelter is about a quarter of a mile from the railroad tracks, but a spur will be put in if the plant is again operated. The Keystone property, 1½ miles from the Arizona United, is owned in Wichita, Kansas. Some work is being done, and the vertical shaft has cut several good veins, one of which was partly explored last summer. There is also on this property a deposit of iron ore, suitable for flux. The Copper Chief properties, now idle, are operated by a vertical shaft, in dolomite, 300 ft. in depth. Last fall several shipments of ore were made, but these did not prove satisfactory, as the ore contained a good deal of zinc, which was shipped under a misapprehension. There has been some good work done on these properties, and considerable ore has been shipped from time to time, mostly high grade. Dissension in the company has hindered operations, but now that a partial reorganization has been effected, matters may improve. The properties lie on the great contact running through the camp, and orebodies of sufficient size and value to be profitable should be discovered. The Black Prince has been worked during the last four years, with R. N. Bell, of Denver, as manager. There is a vertical shaft 935 ft. deep, reaching water-level. This shaft passes through successive strata of limestone, but from the 850-ft. level the material is bluish and shows copper. Several good veins were crossed by the shaft. A Temple-Ingersoll machine drill is in use, and there is a generator for lighting the premises. This is the only deep work in the camp, and the fact that it goes a little below water-level is of great importance. Now the veins crossed may be explored with probability of good results, and sufficient water for all purposes is at hand. The work now in progress consists of exploring the vein on the 650-ft. level, and to some extent the one at 900 feet.

NEW YORK

American Electrochemical Society Meeting. — Hard Times in Wall Street.—Dullness of Porcupine.—Copper Situation Unchanged.—Debut of Miami in Exchange. — Elimination of Heinze. — Goldfield Consolidated.—Nevada-Utah Merger.

The American Electrochemical Society met here this week. On Thursday the Society visited the Laurel Hill works of the Nichols Copper Co. and on Saturday the Perth Amboy plant of the A. S. & R. Co. The meeting was full of interest, and a large membership, including those most prominent in this field, were in attendance. A number of papers were read dealing with the electric furnace and its application to commercial work, and the paper by J. C. Clancy on his new cyanide process was brought up for further discussion. The meeting as a whole was productive of great interest.

This is one of the hardest seasons Wall Street has ever endured. It is not so much the fact that there is no business doing, as it is that Wall Street as a whole is just like a factory owner with a big plant. Operation under present conditions means a desperate loss; to close down is impossible. There has been no comment made upon the men thrown out of employment or the branch offices discontinued, but many men of long employment in the Street are being forced to seek new fields, and the retrenchment all along the line has been drastic and is becoming even more so.

The market in the mining issues has had its centre of interest in the Porcupine stocks, though this week the trading has been strictly pre-holiday in character. . The new Canadian shares have elicited a great deal of public interest, but the handling of the market has not been above criticism. In nearly every case the offerings have suffered sharp recessions from the subscription prices, with the result that traders have felt safe in taking the bear side. The attitude for the present seems to be a waiting one, and Porcupine will evidently have to show cause in full measure before its boom can be launched. The argument heard on all sides is that foreign capital, Englishmen proverbially 'cold-nosed' are going in; this is important to the property owners, the fact remains that the share market in New York has had a decided reaction and will undoubtedly have further recessions in the absence of good news from the camp.

The copper situation remains bad. The increase as shown by the figures of the Producers Association for last month practically put an end to all talk of curtailment policy, and while no producer would be radical enough to admit that he would like to see a further lowering of prices such as would eliminate a large part of the high-cost copper produced by those who can make no money at present market, but who are working rather than face the cost entailed by closing down, yet it is undoubtedly true that such action would clear the atmosphere. There is no question that there is a great deal of copper coming to the market now that shows little or no margin of profit; to revert to the doctrine of the survival of the fittest would be primitive but radical and effective.

It has always been a matter of comment that the New York Stock Exchange never made any particular effort to cut into the business of the Boston Stock Exchange, but allowed the latter to monopolize so largely the trading in high-class copper stocks. Evidently, the acute conditions prevailing are to bring about a change in this regard. This week Miami Copper joined the small but growing group of copper-mining issues on the 'big board'. The statement made by the Miami, in application for trading privileges, shows 663,938 shares issued of a total of $800,000 (par value $5) authorized; 1122 acres of land owned, of which 58 are prospected and developed. Ore reserves are given as 18,000,000 tons of an average copper content of 2.58%. Equipment consists of hoisting plant of 6000 tons daily capacity with crusher plant and conveyor system of same capacity, concentrator of six units with a total rated capacity of 2000 tons. Cash on hand is $351,059. Of the bond issue put out by the company some months ago, there is now out-

standing $1,433,000. It is said that the Consolidated Arizona Mining & Smelting Co., which controls the old smelter at Humboldt, Arizona, in addition to having rebuilt that plant is to erect a custom smelter near Tucson, for the purpose of taking care of the ores from the smaller properties which need a custom plant. F. Augustus Heinze is said to contemplate complete retirement from the field of copper mining. To be sure, there is a hint that such retirement is not wholly voluntary. Mr. Heinze has relinquished control of the Davis Daly to the New England interests, and the contemplated rejuvenation of Ohio Copper is dependent upon the elimination of Heinze.

The Eastern market in Goldfield Consolidated has been something of a disappointment during the current year. There is no sign of decrease in the dividend, the showing in earnings is as strong as it has been at any time since the quarterly disbursement of 50c. was begun, but recently it has seemed impossible for the shares to make any advance. It is quite plain that there is a steady liquidation from some source, the shares being fed out as fast as the market will absorb them. The merger of the Nevada-Utah, Ohio-Kentucky, and the Prince Consolidated seems for some unknown reason to have 'bogged down'. The merger was evidently originally planned with the idea that the Nevada-Utah interests should be dominant in the new company which was to have been known as the Amalgamated Pioche Mines & Smelters Corporation. The Prince and the Ohio-Kentucky are now demanding that the deal be completed by May 1 or be definitely abandoned. Announcement of the completion of the merger has been made several times, but in each instance some hitch seems to have interfered with projected plans.

LONDON

Murex Process. — North Broken Hill and Broken Hill South Silver.—Satisfactory Development.—Stocks on Hand.—North Broken Hill.—New Concentrator.

Progress at Broken Hill is a source of continual interest. A new departure of promise is the acquiring of an interest in the Murex magnetic concentration process by Bewick, Moreing & Co., who will become managers of the Murex company for Australia. W. J. Loring will join the board. I have followed the process with keen interest and have always considered that the management hitherto has been rather lacking in engineering qualifications. The new departure will therefore introduce an important element into the method of carrying out the metallurgical idea. South Blocks Extended is to adopt the process.

On several occasions recently I have referred to the exceedingly sound positions at the North Broken Hill and the Broken Hill South Silver. These are the two brightest spots on the Barrier range, and not only are the developments in the mines excellent, but the metallurgical plants are perfect models in their way. At the Broken Hill South Silver the new concentrating plant was completed at the beginning of 1909, but was not at once put into commission, as the directors had not been able to conclude a satisfactory contract for the sale of the lead concentrate. After the settlement of this question later in that year, another period of inactivity was caused by the Australian coal strike. Some of the zinc tailing used to be sold to the Zinc Corporation, but since March 1910 the whole has gone to the De Bavay company to be treated on joint account. The Zinc Corporation and the De Bavay company are still treating old dumps. The company is in prosperous condition and nothing is now hindering the continuous working of the mine and plant. The amount of ore raised during the latter half of 1910 was 179,117 tons averaging 14.9% lead, 12.9% zinc, and 6 oz. silver. The concentrating plant produced 28,162 tons of lead concentrate averaging 70.4% lead, 5.5% zinc, and 21 oz. silver; and 84,428 tons of zinc tailing averaging 4.1% lead, 18.2% zinc, and 3.7 oz. silver. In addition 22,866 tons of slime was produced averaging 10.7% lead, 12.1% zinc, and 4.9 oz. silver, stored for future consideration, and 43,760 tons of useless tailing averaging 2.2% lead, 7.7% zinc, and 1.4 oz. silver. The zinc tailing was all despatched to the De Bavay company's plant, together with 11,548 tons of dump material; 11,420 tons of dump material was also taken by the Zinc Corporation. The developments in the mine during the half-year have been most satisfactory and the reserve on December 31 was estimated at 3,000,000 tons. It is known in addition that there are large amounts of ore not yet blocked out in the mine between the 970 and 1070-ft. levels. The company also has 1,199,000 tons of dump material on hand, averaging 5.8% lead, 16.8% zinc, and 3.6 oz. silver, together with 238,675 tons of accumulated slime, averaging 11.8% lead, 14.7% zinc, and 5.8 oz. silver. The cost of mining, filling stopes, and development was 12s. 8d. and of concentrating 3s. 6d. The income from the sale of lead concentrate was £212,591, and the receipts on account of zinc tailing £32,089. The net profit was £67,800, out of which £60,000 has been distributed as dividend.

Map Showing Position of Broken Hill.

At the North Broken Hill mine the first part of the new concentrating plant was put into commission in September 1909, and the remainder about midsummer, 1910. The present capacity is 6000 tons per week, but this level has not yet been reached owing to scarcity of mine labor. During the half-year ended December 31 there was a continued increase in the output and profit, and, what is equally important, most satisfactory development. During the six months in question 132,626 tons of ore was raised, of which the largest proportion, 56,690 tons, came from the 950-ft. level; the remainder coming from the 500-ft., 600-ft., 700-ft., 800-ft., and 1100-ft. levels. The amount treated in the concentration plant was 136,044 tons, averaging 15.8% lead, 13.3% zinc, and 6.3 oz. silver, and 23,011 tons of lead concentrate was produced, assaying 70.8% lead, 6.6% zinc, and 20.2 oz. silver. The amount of zinc tailing produced was 67,757 tons, averaging 3.6% lead, 17% zinc, and 3.2 oz. silver. This was sent to the De Bavay company's plant which is situated just to the north of the mine. In addition 15,445 tons of slime was produced, assaying 12.5% lead, 16.3% zinc, and 7.6 oz. silver, together with 29,831 tons of useless tailing. It is of interest to note that a small plant has been built for the treatment of the slime, and that the results so far obtained are promising. As regards ore reserve it is estimated that there are 1,500,000 tons available above the 1100-ft. level. At two points on this level the orebody is over 70 ft. wide.

General Mining News

ALASKA

KENAI PENINSULA

The Kenai-Alaska Gold M. Co., the property of which is at mile 24 on the Alaska Northern railroad, which extends from Seward northerly 75 miles, has driven a 400-ft. adit, by which bodies of free-milling ore have been opened. It is said this ore samples about $30 per ton. Some additional equipment has been ordered that will be in place in a few weeks. Seattle capitalists have secured the controlling interest in the Alaska Gold Quartz Mining Co., embracing five claims on Willow creek, back of Knik. The quartz is reported as being very rich and the three-stamp mill which is now on the property will be increased to a seven-stamp during the coming summer.

The Canadian interests behind the Alaska Northern are planning to extensively develop the tributary territory, and with the opening of the summer season expect to play a most important part in the quartz development of that portion of Alaska. Many experienced quartz miners are making up parties for a thorough study of the Alaska situation; these parties being largely drawn from Butte, Montana, and the Nevada camps.

A party of Salt Lake mining men has been formed to operate a large number of claims in the Lake McKinley district, another section which is making a favorable showing and which is just coming into life on account of the fact that it is tributary to the Copper River road.

THE KOYUKUK

George Gregson, who mushed out to Gibbon from the Koyukuk in February, reports much development on Sheep creek where pay-dirt was found on the benches, and he predicts a good clean-up there this season. Good pay was found, also, on Nolan creek, where several claims will be worked this year. A Keystone drill is to be taken in this spring for prospecting on South Fork. Work continued through the winter in the Koyukuk camps, getting out pay-dirt for summer sluicing.

PRINCE WILLIAM SOUND

Charles Crawford is building a stamp-mill at Valdez for treating custom ores. The Valdez M. Co. is having an adit-level driven alongside the vein in one of the walls. The ore disclosed contains gold, galena, and iron. The Biglow brothers, with W. D. Nutley, are outfitting at Chitina for extensive prospecting and development work in placer operations on Slate creek, which is 190 miles from the new town of Chitina. They are making ready to leave for the interior with a most complete outfit, and as this country has not been extensively explored in the past, the results are awaited with interest.

ARIZONA

COCHISE COUNTY

It is reported that plans have been made for the construction of a new smelter by the Calumet & Arizona Mining Co., consisting of McDougall roasters, two 60-ft. blast-furnaces, and five reverberatories. A definite announcement is expected after the annual meeting.——It is understood that final plans have been made for re-opening the Tombstone Consolidated Mining Co.'s properties. Arrangements have been made for retiring the indebtedness of the company, and the probable re-opening of the mines has greatly encouraged the district as a whole. The Hershall is working a full force and the Bisbee Extension has five men at work. The 300-ft. brick stack for the reverberatory furnaces and McDougall roasters at the Copper Queen smelter is in course of construction. The base is more than 35 ft. in diameter, the walls being 3 ft. thick. The first 40 ft. is of red pressed brick and the rest is of tiling. It is expected to complete the work early in July.

GREENLEE COUNTY

The Shannon (formerly known as the Copper Belle) is shipping a car of ore a day to the smelter at Clifton to be used for smelting purposes.

MOHAVE COUNTY

The U. S. S. R. & M. Co. has made a substantial cash offer for the Gold Road mine, after a thorough investigation by Jennings and Holden. The ore averages about $8 per ton and is suited to cyanidation.

PIMA COUNTY

(Special Correspondence.) — The announcement in the *Tucson Star* of an enormously rich strike in the Arivaca district is entirely unfounded. The Arivaca district is as yet undeveloped and while the surface showings are good and encouraging results are being obtained from prospecting, no tellurium ore has ever been discovered and no development work has been done in any other than the

Central Arizona.

Oceanic mine, which is an old, well known property, at present shut down, pending a sale. The visit of Mr. Wiseman to the district was not connected with business matters. The lease referred to in the newspaper account had only a two-inch streak of ore, and after sinking on it for 23 ft. the lessees abandoned it.

Arivaca, April 8.

PINAL COUNTY

Good vanadinite ore has been found in the Shamrock mine in the Casa Grande district, and Mr. Meehan says that he has a 16-ft. vein. The ore carries $5 per ton in gold, 460 lb. of lead, and 216 lb. of vanadium pentoxide. Vanadium ore also occurs in the Orizaba mine, a mile west of the Shamrock.

CALIFORNIA

BUTTE COUNTY

(Special Correspondence.)—Within a short time a comprehensive test will be made of a new type of dry-land dredge in this district. The dredge, which is being constructed for L. N. Hearn and associates, will be provided with a steam-shovel in place of the customary bucket line, and will be mounted on rails, instead of floating on water. It is expected that the new type of dredge will facilitate the profitable dredging of shallow ground, and also allow the working of small acreages, where it would not be possible to economically operate an ordinary dredge. The new dredge will be given its try-out on land owned by the firm of Rideout, Smith & Co. It is expected to have the dredge in commission within a few weeks. Natomas Consolidated is pushing work on its 15-cu. ft. dredge, recently delivered at Thermalito. The completion of this monster will be the first advent of the 15-cu. ft. type in this district, although the Natomas is operating a similar boat at Folsom with success. J. C. Boyd, of Sacramento, has been delegated by the Anti-Débris Association to make another examination of dredging conditions at Oroville. Mr. Boyd recently completed an investigation, but the anti-débrisites do not appear to be wholly satisfied. In the Magalia district much work is going on. Eastern people recently took a bond on the Eureka and are pushing development. At the Robbers Roost mine, E. H. Young

and associates of New York are finding gravel of fair grade.

Oroville, April 15.

INYO COUNTY

There is great activity at Keeler, following the discoveries which have been made in the leases on the Sam Kee and Whittier properties, and a promotion club has been organized to forward the development of the district. It is reported that a 12-ft. vein of shipping ore has been uncovered in the Sam Kee. Many leases are being let; the first team-load of ore went over the new road on April 3, and a 6-horse load of ore came in from the Shively on Sunday. L. D. Gordon has taken a lease on the Cerro Gordo and has about 500 tons of zinc ore ready for shipping; work being confined to the 400-ft. level. A new rate of $8.50 per ton from Keeler to Oklahoma has been secured. It is expected to ship a 20-ton car every day in the future.

KERN COUNTY

The Guaranty Oil Co. has made an alliance with the American Oil Fields Co. by which the former receives 120 acres of patented land in the Midway field, while the latter secures 25% of the carrying capacity of the pipe-line to be built to the coast by the Guaranty Oil Co. There is great activity in the mines of the Rand district; the Atolia has 100 men at work and more than 50 miners have found work in new enterprises and old ones that are increasing their forces. Edwin Higgins has been appointed manager of the La Crosse mine. The Ajax is finding good ore, and the Sunshine has good ore on the 200-ft. level. The stamp-mill at the latter will soon be started again.

NEVADA COUNTY

Eighty men are at work in the Champion mines on Deer creek, 20 of them exploring on the account of the North Star Mines, which has an option on the property. It is expected that the Morning Star and Siberia mines will soon be re-opened. These promising properties have been closed down for some time.

PLACER COUNTY

The Beaver Dredging Co.'s dredge on Dry creek is making rapid progress, and the necessary surface buildings are being constructed. H. B. Morse is retimbering the old Pioneer mine on which he has a bond. The stamp-mill at the Herman will be increased to 30 stamps. The sawmill will be started as soon as the roads are open. The Last Chance mines are working 100 men and maintaining a steady production. R. H. Young has struck some rich ore in the Annie Laurie, and the clean-up from the crushing of 18 tons at the Malmberg mill gave big results. A shaft will be sunk at the Crandall mine and drifts driven to cross-cut the ore which Mr. Norten, the superintendent, has found.

PLUMAS COUNTY

Samuel Alebuster, of San Francisco, according to the *Plumas Independent*, has taken a lease on an area covered with tailing from the Crescent and Green Mountain mills, and will proceed to cyanide it. Bids have been invited for furnishing 1000 cords of wood and for hauling 57½ tons of freight, consisting of engines, boilers, and other material from Keddie station to Crescent Mills.

(Special Correspondence.)—The Engels Copper Co. is proceeding with the erection of a 50-ton smelting plant at Light's canyon; 20 men being employed in installing the machinery. Towers for a tramway, 7500 ft. long, have been erected, and construction work on the tramway will be resumed early in June. At the mine two shifts are employed in development, and it is stated that an excellent reserve of high-grade copper ore has been opened. The blowing-in of this smelter marks the first effort at copper smelting in this county, and it is expected that the close of the year will find the company an important producer. The company is controlled by the Engels brothers of San Francisco. Several Eastern companies have also become interested in the copper deposits in the Genesee and Copper Hill sections, and exploration has been productive of satisfactory results. The Engels company has purchased a 60-hp. automobile truck to facilitate the shipment of supplies from the Western Pacific station at Keddie to the mine, which is situated at Taylorsville in Indian valley. The Plumas Power Co. was recently formed by San Francisco people, for the supply of power to the mines in the Indian Valley district. The company plans to develop 1200 kw. Operations are about to be resumed at the Gold Mountain hydraulic mine, near Quincy. A large quantity of pipe is being laid. G. W. Fagg is superintendent. Driving for the orebodies on the Seventy-Six portion of the property is progressing steadily at the Plumas Eureka, near Johnsville. This famous property, which has paid $2,831,294 in dividends, is one of the premier producers of the entire county. The Ebert quartz mine has been acquired by the California Con. Gold Mines & Exploration Co., an Arizona corporation.

Quincy, April 14.

SHASTA COUNTY

R. T. White has resigned as general manager for the Balaklala company and will go to the Braden copper mines in Peru. The farmers are awaiting the report by Mr. Gould as to the amount of solids which are being removed from the gases by the Cottrell process, and developments are expected soon. George Bayhew, who was instrumental in the sale of the Evening Star mine for $125,000, has taken a bond on the Texas group, which has lain idle for some years.

SISKIYOU COUNTY

The Siskiyou Electric Light & Power Co. announces that it will extend its lines to Klamath falls and Butte creek valley. Work will be started on a 90-ft. dam to impound the waters of the Klamath river and develop 30,000 hp. The large amount of power which this will make available will permit the development of many enterprises throughout the county. L. E. Buckner and Peter Walls, who have a lease on the Overton mines on Cow creek, made a rich strike last week, the ore taken out during the week is said to have realized $7000. This mine has been noted for years for its rich specimen ore.

TRINITY COUNTY

In our Trinity county news of April 8 it was stated that the La Grange mine was included among several properties which had been taken under option by persons representing the Guggenheims; and we have been informed since by P. Bouery, manager for La Grange M. Co., that the statement was an error so far as it related to the La Grange mine.

COLORADO

CHAFFEE COUNTY

The Low Pass M. Co., owner of the Belle of Granite mine, at Granite, has discovered rich ore in a 5-ft. vein, which formerly yielded high-grade ore. The ore blocked out is estimated to be worth $100,000. That on the dump, placed there years ago, is considered profitable now when treated by present milling methods. The equipment includes an old mill which is to be improved with new machinery. A water-power plant is to be established.

CLEAR CREEK COUNTY

(Special Correspondence.)—J. R. Claypole, of Cripple Creek, has been awarded the contract to drive the Lucania adit 1500 ft. The electric-driven compressor at the Lamartine mine has been purchased and will be placed in position during the coming week. The heading is now in a distance of 4800 ft. The Old Town M. M. & T. Co. has been orgauized to carry on development work, which will be in charge of G. K. Kimball. Shipments are going out from the Blue Ridge mines on Columbia mountain. The 50-ton concentrating plant will be started May 1.

Idaho Springs, April 10.

LAKE COUNTY (LEADVILLE)

The London mine, situated at a high altitude on Mosquito range, close to the line between Lake and Park counties, is reported to have been subleased for a term of 20 years to a syndicate of Eastern men, by which work has been commenced. One of the projects of the syndicate

is to put in equipment for electric power at the mine and build a surface tramway to the property from Alma. Another is to open the great vein at 2000 ft. depth by driving two cross-cuts—one from the north side and the other from the south side of London mountain. These cross-cuts are to open the vein at widely separated points, which will be connected by a drift on the vein. The old workings are entered through a higher adit-level, and a winze that was sunk from that level on the vein. When the two projected cross-cuts shall have been driven, and connected by a drift, the great working level thus established is to be connected with the winze so as to secure ventilation, and to permit the passing of ore from the old workings to the haulage level. This plan, where worked out, will serve to drain the workings and relieve the operators of the expense of hoisting ore and waste. The London is principally a gold mine, some of the ore extracted in past years having been high grade. J. M. Kuhn is the original lessee, who has subleased to the syndicate which is to undertake the work outlined.

The Leadville *Chronicle* estimates the output of zinc carbonate ore at 250 tons per day, and anticipates an increase by May 1. The tonnage of zinc sulphide is increasing, a portion of which has to be concentrated before shipping.

SAN JUAN COUNTY

Development work in the Gold King mine has been kept up all winter, with the result that a large tonnage of ore is now in the bins, and broken in the stopes. The mill at Gladstone is being put in condition to operate, and the Gladstone & Northerly railroad, which extends from Silverton up Cement creek to Gladstone, is being repaired; also, accommodations for miners and millmen are being provided. Within the next few weeks the mine and mill are expected to be in operation. The Ledge Con. M. Co., with R. W. Hollis as superintendent, has performed important development during the winter, the result of which is that the shaft now has a depth of 517 ft., and drifts in ore have been extended some distance both north and south from the sixth station, showing the vein to be 5 to 6 ft. wide. The ore is of profitable grade, carrying gold, silver, lead, and zinc. Development on the third and fourth levels has exposed new orebodies in those places. The mill is being provided with some new equipment, including four jigs, set of rolls, and Callow tanks. The Silverton *Miner* states that the Hamlet mine, situated between Howardsville and Eureka, is to be worked this season under direction of Etienne A. Ritter, of Colorado Springs, consulting engineer for those having a bond on the property, the price specified in the bond being $150,000.

SUMMIT COUNTY

The mine and mill of the Colorado-Toledo M. Co. are operating at Collier mountain, near Argentine, the mill being expected to treat 100 tons per day. The New Pennsylvania Mines Co. is having its mill repaired, and will soon have it in operation.

TELLER COUNTY (CRIPPLE CREEK)

The Vindicator Con. Gold M. Co., owning about 80 acres at the foot of Bull hill, near Goldfield, is operating through two principal shafts, No. 1 and Hull City, and is mining at a depth of 1400 ft., having about 30 miles of development. There is a working force of 200 men. The March output amounted to 3540 tons of ore of an average value of $30 per ton. Of this production, 2880 tons was taken from the drifts and stopes tributary to No. 1 shaft, and 960 tons was hoisted at the Hull City, while 300 tons was shipped by lessees at the Glorietta and other minor shafts. The ore is shipped to the mills in the valley. The mills which are operating on Cripple Creek ores treated a big tonnage in March, the Portland handling 10,000 tons, and the Golden Cycle nearly 25,000 tons. The Cresson mine is keeping up a production of 2500 tons of ore per month. It is reported that the United States Reduction & Refining Co. has just put into effect a treatment rate of $6.50 per ton on ore sampling 3 oz. gold per ton or less, and $7 per ton for ore containing an excess of 3 oz. gold, which amounts to a reduction of 10% from former charges. It is anticipated that this cut will be met by those operating other plants.

IDAHO

LEMHI COUNTY

The Pittsburg-Idaho company, operating a lead-silver mine at Gilmore, shipped 15,000 tons of ore to the United States smelter at Midvale, Utah, between July 1 and April 1, which sampled 36% lead, and 15 oz. silver per ton. The Pittsburg & Gilmore railroad, which extends from Armstead, Montana, to Salmon, Idaho, has a branch line from Junction to the vicinity of the Gilmore mine. New equipment is being put in at this property. A dividend of $10,000 was paid April 12.

SHOSHONE COUNTY

The Success Mining Co., controlled by H. F. Samuels, of Wallace, and his Spokane associates, has paid all indebtedness, and recently paid a dividend of $15,000. The Success mine, situated on the north fork of Nine Mile creek, 4½ miles from Wallace, is a producer of zinc and lead ore. In the past the zinc product was of most importance, but on one of the two veins a strong shoot of galena has been opened on the lower levels which is giving the lead output first place. The Monarch mine, situated in Murray district, is producing 100 tons of ore per day, which is being concentrated, and it is announced that this tonnage will be doubled next month. The property belongs to the Coeur d'Alene North Fork M. & S. Co., for which E. P. Spalding is manager. The main haulage level extends 3200 ft. into the mountain ridge between Pritchard creek and Barton gulch, and this cuts the vein system at a depth of 1400 ft. It is stated that a 250-ft. winze is to be sunk from this level. Other producing mines of the Murray region include the Black Horse, Jack Waite, Bear Top, and Terrible Edith. The Paragon is considerably developed and has some good bodies of ore.

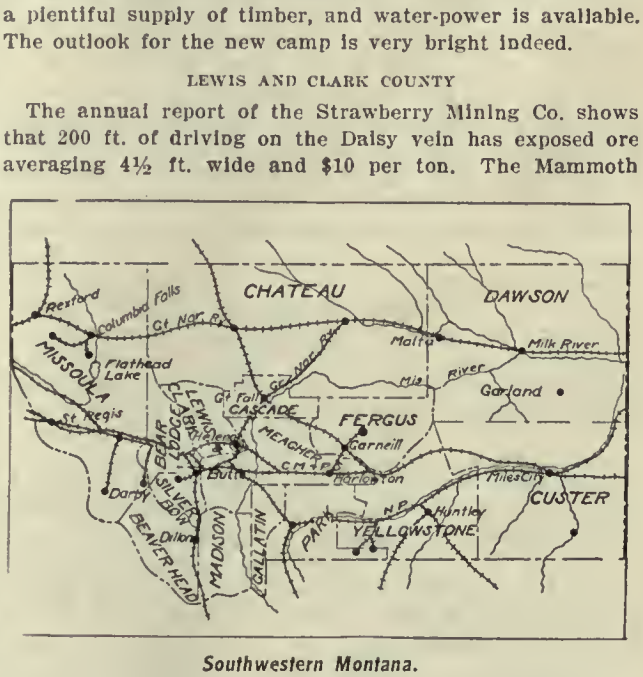
MONTANA

BEAVERHEAD COUNTY

Recent reports from the Elkhorn district are to the effect that the Central Group, owned by Dillon interests, has eight veins, the largest of a width of 27 ft., the ore averaging 4% copper, 12 oz. silver, and $2 gold. There is a plentiful supply of timber, and water-power is available. The outlook for the new camp is very bright indeed.

LEWIS AND CLARK COUNTY

The annual report of the Strawberry Mining Co. shows that 200 ft. of driving on the Daisy vein has exposed ore averaging 4½ ft. wide and $10 per ton. The Mammoth



Southwestern Montana.

vein has also been cut and shows an average of about $10 over 5 to 7 ft. The new mill was expected to start on March 10.

SILVER BOW COUNTY

The North Butte has struck another vein which is reported to be even richer than any yet found in the property. The vein was struck at a depth of 2750 ft. and is

from 15 to 17 ft. in width, a large portion of the ore running as high as 22% copper. Like other finds in the North Butte, few particulars can be learned, but there is no question as to the authenticity of the report, as a prominent person connected with the company has acknowledged the correctness of the story. However, no definite statement will be given out. The Edith May vein is expected to be cut on the 2800-ft. level. The ore on the 1800-ft. level continues to be as rich as when first uncovered, while on the 2400-ft. level the ore runs from 9 to 11% copper.

The Raven company is now driving on the 200-ft. level of Snoozer, but so far as can be learned no ore of a commercial quality has been found. A force of men is at work in the Raven mine doing extensive development work, but if any ore has been found the management is keeping the matter strictly quiet.

NEVADA

ESMERALDA COUNTY

At the Goldfield Consolidated, J. W. Donnelly, the mine superintendent, has organized a rescue team which is shown at practice in the illustration. It consists of eight picked miners, men who are most familiar with the underground workings, furnished with Draeger oxygen helmets. Suitable training quarters have been provided, and practice is

Mine Rescue Team, Goldfield Consolidated.

held every change day. The men all take great interest in the work. While Rescue Car No. 4 was in Goldfield, Sumner S. Smith and his men gave this team thorough training in the use of helmets and in first-aid work. The suit of the Goldfield Consolidated against D. McKenzie for damages sustained by a cave-in in the Mohawk while the latter was operating it under a lease will be tried before three district judges, sitting *en banc*, and their decision will be accepted as final.

The Coalition Mining Co. produced bullion during March to the value of $23,000, making a total since the first of the year of $68,384.43. There is a steady increase in production each month, and it is confidently expected to pay the initial dividend before the close of this year. The lower levels look better, especially the sixth.

LYON COUNTY

It is reported that oil has been found in the well which was drilled for the smelter at Wabuska, and high hopes are entertained of being able to perhaps secure a supply of fuel oil. A small crew is at work in the Nevada Douglas putting the raises and levels in shape to produce ore as soon as the railroad is completed to the property and the smelter is ready.

NYE COUNTY

The March report for the Tonopah Belmont shows that 8295 tons was treated, 3957.323 oz. gold bullion and 386,626.10 oz. silver bullion were produced at a net profit of $169,336.91. The March report for the Tonopah Mining Co. shows that 14,078 tons was sent to the mill, with a resulting bullion recovery of $210,185. Concentrate to the value of $51,360 was shipped, the net profit for the month being $147,678.

(Special Correspondence.)—The Big Four Leasing Co., operating on the Manhattan Big Four mine, has placed orders for a 10-drill air-compressor, two Knowles pumps, and other equipment. The compressor is of the Imperial type, manufactured by the Ingersoll-Rand Co. It is expected to commence the installation of the equipment within three weeks. The shaft is advancing rapidly and will soon attain the 300-ft. point. From here lateral work will be pushed. On the 220-ft. level a north and south drift is being advanced rapidly, and considerable ore is being extracted. About 100 tons of ore is on the dumps, and this is being increased as development continues. It is understood that the ore showing has been so encouraging that the company has decided to install its own mill. The War Eagle mill is handling 300 tons of ore from the workings of the Dexter L. company on Union No. 9 claim of the Dexter Consolidated. At the Morning Star, George Durgin has started the sinking of a new shaft. At a depth of 10 ft. a new vein, one foot wide was discovered and is showing greater width as developments progress. The old shaft is 135 ft. deep, with encouraging showings. Durgin states that he may install a small mill during the summer. Conditions are generally improving in the Manhattan district, and the outlook is for an animated summer. Several leases on the Blue Jacket property at Round Mountain report the opening of ore averaging $20 to $40 per ton. A recent shipment to the mill by the Gibson-Kemont-McVeigh lease netted $47 per ton.

Manhattan, April 13.

The gross output of the mines of the Tonopah district for the week ending April 8 was 8353 tons, of an estimated value of $209,000. To this the Tonopah M. Co. contributed 3350 tons; the Belmont, 2803; Montana, 1000; Tonopah Extension, 980; West End, 200; and Midway, 50. The district in general shows continued improvement.

J. R. Davis, manager of the Round Mountain Mining Co., will submit his report for the year 1910-11 on April 17. It will show that the company as well as the mine is in better condition than ever before. On Feb. 28 the cash in bank and bullion in transit amounted to $60,338.42, while the ore blocked out in reserve amounted to 111,928 tons. Contracts have been made for the machinery to increase the capacity of the mill 50 tons per day. This machinery is expected to be in operation within 60 days, with a resulting one-third increase of the earning power of the mill. J. P. Sweeney has sent circulars to the shareholders and will probably attempt to gain control at the meeting.

OREGON

JOSEPHINE COUNTY

The Circuit Court for the District of Oregon has handed down a decision affirming that the United States may issue patents to mineral claims within the grant of a military road. This, by extension, would also apply to mineral claims within the lands of the Oregon and California railway grants.

UTAH

BEAVER COUNTY

(Special Correspondence.)—This district is showing considerable activity with the opening of spring. The South Utah, which commenced operations in September 1910, has made profits as high as $10,000 per month. This is a good showing considering the fact that the ore is of very low grade and that the mill has been treating only 700 tons per day. After many delays the 100-ton concentrator of the Horn Silver has been started up. The ore treated runs 10 to 12% lead, with 8 to 10 oz. silver. About 25,000 tons of this grade is stored in the old stopes and a large additional tonnage is blocked out, so that there is sufficient ore in sight to run for some time to come. Power is generated in the company's steam-electric plant. The operation of the mill will make practically no increase in the working force, as a considerable amount of labor has been required in the past to store the milling ore. A 5-stamp amalgamation mill has been erected at Beaver City to treat the ore of the Sheep Rock mine. The mill was brought over from Marysvale canyon. The Busy Bee,

eight miles east of Beaver, and in the same mineral belt with the Annie Laurie, is planning the erection of a 10-stamp mill on Indian creek. The Imperial, near the South Utah, has commenced a shaft which will connect with a winze in one of the tunnels and give a depth of 140 feet.

Milford, April 15.

JUAB COUNTY

(Special Correspondence.)—At the annual meeting of the May Day the old officers were re-elected and the annual report submitted. This shows that within the past year the company has paid off the indebtedness with which it entered the year, has shipped ore and concentrate of the value of $70,000, done extensive development work, and has $4000 in the treasury. One assessment of $16,000 was levied. The new orebody found in the Eagle & Blue Bell appears to be a continuation of the rich vein recently opened by the Victoria. Work has been carried on in it for about three weeks, and, although it does not show the high value of the Victoria, the ore is of good shipping grade. The King William has started a new drift from its main level. The appearances are that Beck Tunnel in its new drifts near the Uncle Sam lines is above the large orebody that was opened by the latter property, and sinking will be tried in an effort to find it. A contract has been let to sink the Swansea shaft another 150 ft. A drift will also be driven on the 1000-ft. level. The Brooklyn Zinc Co. is in the process of organization to develop six claims near the Scranton. This will give the district another zinc mine. Total shipments for the week from the district are 187 cars, Centennial Eureka leading with 44 cars, and Iron Blossom second with 42. The week previous there were 189 cars, Centennial Eureka 47, and Iron Blossom 46.

Eureka, April 15.

SALT LAKE COUNTY

(Special Correspondence.) — Work on the 500-ton lead plant at Tooele has been commenced. It is planned to have the plant ready for operation by August 1. Lead ore is already being shipped in, and about 2000 tons is now on the stock pile. The Utah Consolidated has increased its shipment of copper ore, and is now sending in 500 tons daily. About 800 tons per day is being treated. There are prospects that a fight for the control of Utah Consolidated will be waged at the annual meeting on April 18. The company earned only 4.35% during the last year. Proxies are being sought to be used against the present management at the meeting. The Utah Apex company has found 14 ft. of ore running 30% lead in its No. 2 workings. This company has been developing since the mill was shut down last fall and has blocked out a large tonnage of ore. In another portion of the mine a find was made of ore carrying 6% copper, and 33% iron. The Bingham-New Haven has declared a dividend of 20c. per share, bringing the total up to $135,000.

Bingham, April 15.

SUMMIT COUNTY

(Special Correspondence.)—The Daly West has declared a dividend of 30c. per share. The mill-men employed at the Silver King Coalition concentrator have gone on a strike for an eight-hour day. The men worked ten hours when the mill was operating only one shift, but refused to work more than eight when a second shift was put on.

(Special Correspondence.)—The American Exploration Co., controlled by F. B. Bodfish and his associates, has commenced the work of driving a cross-cut for 3600 ft., the purpose of which is to drain various old mines of the Alta camp, including the Copper, Prince of Wales, Davenport, Grizzly, and City Rocks at depths ranging from 600 to 1000 ft. The starting point is in Silver fork of Big Cottonwood canyon, the course is southerly, and the mines referred to are situated on both sides of the divide that separates Big Cottonwood from Little Cottonwood canyon. One of the main objects is to tap the limestone-granite contact on the Alta side. The advantage in entering this mineralized region by an ore-haulage and drainage adit from the Big Cottonwood side is the accessibility of that side by a good wagon-road and its comparative freedom from snowslides. This company has control of the American Flag mine, at Park City, in which large bodies of low-grade ore have been exposed during the last six months. The building of a concentrating mill to treat those ores is contemplated.

Park City, April 20.

WASHINGTON

FERRY COUNTY

(Special Correspondence.) — The Insurgent Gold Mining Co. paid its first dividend March 31, of 1¼c. per share, amounting to $12,500. The Hope company has resumed work at the winze on the Black Tail vein, below the adit. A foot-wall assay of $113 was $61 in gold and $52 in silver. A general sample assayed $55 in gold and $40 in silver. In the North San Poil raise a black flint streak assays $30 per ton. In the back the pay-shoot is about 6 ft. wide, and some of the assays continue high. The shaft is 128 ft. deep. At a depth of 70 ft. a 2-in. streak was thickly studded with native gold. The back of the raise is 90 ft. above the adit-level, and there remains about 115 ft. of the pay-shoot unbroken between the two workings. At about 75 ft. up from the bottom of the raise the shoot was from 10 to 12 ft. wide. At 45 ft. above the floor of the adit-level a drift has been started to run on the course of the vein, N. 30° W., to cross the streak going down from shaft, on its rake northward.

The Imperator-Quilp Co. is sacking ore on the 500-ft. level of the Quilp mine, from a body 12 to 24 ft. wide, which averages about $200 per ton. On the adit-level samples assay over $400, and run as low as $8 or $9 per ton. On the 200-ft. level the pay-shoot is 28 ft. wide, and the daily samples assay about $30 per ton. The 50-ft. level (where the native silver was found), is continuing about 5 ft. wide. The mine is now sending out to the smelters about 25 tons per day. The Republic Mines Corporation is shipping now about 50 tons of ore daily. On the 600-ft. level of the Surprise a streak 6 to 7 ft. wide assays from $20 to $40 per ton. The Knob Hill mine looks better than ever. The heading of the north drift on the No. 2 level is still in a good grade of ore. Smelter returns from five carloads are as follows: Two cars assayed per ton 3 oz. gold and 10.70 oz. silver; total gross value, $65.56 per ton. Two cars, 2.82 oz. gold, and 10.6 oz. silver; total gross value, $62.91 per ton One car, 2.57 oz. gold, and 10.8 oz. silver; total value, $57 per ton.

STEVENS COUNTY

(Special Correspondence.)—The drift on ore in the Gem mine, on Toulon mountain, Orient district, shows a breast of ore 7 ft. wide, assaying high in gold, some of which is in free particles. The Orient Gold Mines, Ltd., is sinking a shaft, the ore opened at the bottom of which contains chalcopyrite intermixed with galena.

Orient, April 5.

MEXICO

GUANAJUATO

The annual report of the Guanajuato Reduction & Mines Co. for 1910 shows that during the year the company milled an average of 19,000 tons per month, chiefly from the dump. Milling and cyaniding costs show a marked reduction, and after paying all expenses, including 6% on its bond issue of $2,800,000, the company earned a profit of $146,767. This company is controlled by the American Finance & Securities Co. of New York.

The mill of the Tajo de Dolores bas been completed and is now in full operation. It has 40 stamps and the ore is treated as slime by the continuous process. In the mine, which is connected to the mill by a two-line tramway, enough ore has been blocked out to furnish a two years supply. At the Peregrina mine of the Guanajuato Development Co. a large tonnage of ore from the Villalpando is being treated. The Cubo M. & M. Co. has shut down its mill. Unwatering at the Loreto mine has been completed and three shifts will immediately be put at sinking and cross-cutting. Good ore is being taken out of the Santo Nino and shipped to the Dwight Furness Company.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. F. Shaw is in Lonon.

D. A. Lyon is in Europe.

Louis Janin is in San Francisco.

R. P. McLaughlin is in Wyoming.

R. P. Russell is in San Francisco.

H. C. Hoover has returned to London.

E. F. Burchard was at St. Louis recentiy.

E. G. Hothorn has been in San Francisco.

C. A. Fisher was at Casper, Wyoming, recently.

Edwin Letts Olliver has gone to Portland, Oregon.

F. J. H. Merrill is examining oil lands in Wyoming.

J. M. Callow has returned to Salt Lake from Arizona.

E. W. Carson, of Los Angeles, is at Goldroad, Arizona.

J. Nelson Nevius was in San Francisco and has gone to Utah.

Ernest A. Haggott will be in Arizona tili May, on mining work.

E. B. Kimball is at the Adler Sanatarium, San Francisco, with a broken arm.

J. A. Burgess is superintendent for the Nevada Wonder Mining Co., Wonder, Nevada.

Siegfried Maurer is assayer for the Long Valley Gold Mine Co., at Quincy, California.

Jesse J. MacDonald is on an extended professional visit to the San Juan oilfields of Utah.

Lyon Smith is mili superintendent for the Tonopah-Liberty M. Co., Tonopah, Nevada.

L. B. Eames is visiting California in the interest of the Dorr Cyanide Machinery Company.

H. F. Lefévre has returned to New York after an absence of two months in Central America.

A. Bement has removed his office from Fisher building to 206 So. La Salle street, Chicago.

W. L. Saunders delivered the Class Day Address at the Michigan College of Mines, April 20.

F. O. Martin has returned to San Francisco from an examination of the Lost Hills oilfield.

Glenn K. McKenzie is with the U. S. Reclamation Service, in the vicinity of Pendleton, Oregon.

Ferdinand McCann is temporarily at Hostotipaquillo, Jalisco, acting as manager for El Favor Mining Company.

F. O. Jasmer, superintendent of cyanidation for the Yoquivo Development Co., Chihuahua, has been visiting San Antonio, Texas.

Joseph Jaffa, of Denver, Colorado, gave ten lectures on 'American Mining Law' at the Missouri School of Mines, from March 20 to March 25.

Paul W. Gaebelein, formerly with the Golden Cycle Milling Co., is now consulting engineer for the Colorado Metals Extraction Co., of Denver, Colorado. He will be assistant to W. L. Bain at the Denver plant.

Samuel Calvin, who died at Iowa City, April 17, was born in Wigtonshire, Scotland, in 1840. He removed to Iowa when but a boy, and is best known for his work as a professor in the State University of Iowa and as State Geologist. The comprehensive reports on Iowa geology made by the present Survey have all been written under his supervision and the present advanced state of knowledge regarding the mineral resources of that State is largely due to his energy and ability. He was a man of high ideals and singularly lovable character who devoted himself unselfishly to his profession. He leaves a record of clean, honest work, and of distinguished service.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MOTION STUDY. By Frank B. Gilbreth. 5½ by 8 in. Pp. 116. Ill., index. D. Van Nostrand Co. New York, 1911. Price, $2. For sale by *Mining and Scientific Press.*

In this book are told in detail the methods used by Mr. Gilbreth in standardizing bricklaying. It is part, and a most important part, of the growing literature of 'efficiency engineering.' The methods used are widely applicable.

CRIPPLE CREEK MINES YEARBOOK, 1911. By Colorado Springs Mining Stock Association. Distributed by the Frank Hervey Pettingell Co., Colorado Springs. Price, 25 cents.

This is an official summary of the certified reports of all the listed companies operating in the Cripple Creek district. It is an invaluable handbook for those interested in Cripple Creek mines.

LOCKYER'S DIAGRAM FOR CYANIDE OPERATIONS. 30 by 36 inches. Price $2.50. For sale by *Mining and Scientific Press.*

This is a particularly convenient wall diagram, showing by inspection the solution content of any vat through a wide range of depth and diameter. It is clearly printed, mounted on heavy linen, with a varnished surface, so that it may be posted at any place in the mill convenient for easy reference. How much cyanide is required to bring the solution up to any required strength can be found by inspection, and the diagram should prove very useful to cyanide engineers.

ELEMENTS OF GEOLOGY. By Eliot Blackwelder and Harlan H. Barrows. 8vo., Pp. 475, Ill., index. American Book Co., New York, 1911. Price $1.40.

This is a thoroughly new textbook. As the authors state, it is neither a manual nor reference book, but it is well designed to rouse and hold the interest of the intelligent beginner. The material is fresh, well written, and well illustrated. It is the sort of book that, in the hands of a good teacher, can be used with high school pupils, or without a teacher can be recommended to the mature prospector or others who want to know the elements of the science of geology.

SMOLEY'S PARALLEL TABLES OF LOGARITHMS AND SQUARES. By Constantine Smoley. Sixth Edition. 5 by 7 in. Pp. 174; flexible back. The Engineering News Pub. Co., New York, 1911. Price, $3.50. For sale by *Mining and Scientific Press.*

The new edition of this well known work includes a table of natural functions giving the sine, cosine, tangent, cotangent, secant, and cosecant by intervals of one minute. Other additions are tables of squares, cubes, square roots, cube roots, reciprocals, areas, and circumferences of circles. The book is convenient in form, and well printed, with type that is unusually large and clear for a pocket book.

ELEMENTARY CHEMISTRY FOR COAL-MINING STUDENTS. By L. T. O'Shea. Pp. 319, Ill., index. Longmans, Green & Co., New York, 1911. Price $1.80.

This is not a textbook of chemistry, but a compilation of the parts of chemistry related to coal mining. Mr. O'Shea, who is professor of applied chemistry in the University of Sheffield, has made good selections as to the material to be included and a helpful book is the result. It is not, however, as elementary as might be inferred from the title, and the men who most need it, in America at least, will not always find the text simple. However, the subject itself is complex, and that the book should be full and accurate is more important. The book is well printed and bound and is the best one available in its field.

Recent Publications

BRITISH GUIANA. The Permanent Exhibition Committee has recently sent out leaflets describing the 'Rice Industry,' 'Sugar Industry,' and 'Balata and Rubber Industries.'

STRATIGRAPHY OF THE OLDER PENNSYLVANIAN ROCKS OF NORTHEASTERN OKLAHOMA. By D. W. Ohern. State University, Oklahoma, Research Bull. No. 4, Pp. 40, map. Norman, 1910. A résumé of results of a systematic re-study of the region.

REPORT OF THE STATE ENGINEER. [CALIFORNIA.] Pamphlet. Pp. 180. Sacramento, 1911. This report covers the period from November 30, 1908, to November 30, 1910, and deals with harbor work, river control, road construction, topographic surveys, water supplies, and similar subjects.

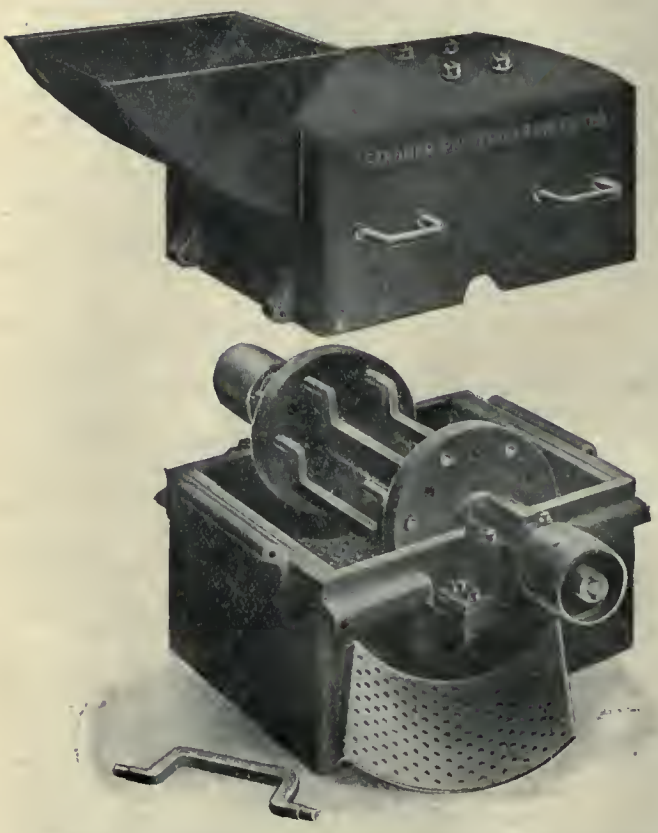
DEPARTMENTS OF MINES (CANADA), reports recently issued include: Bulletin No. 5, 'Magnetic Concentration Experiments,' by George C. Mackenzie, 27 pp. 'Investigation of the Peat Bogs and Peat Industry of Canada,' by Alfred Aurep, 44 pp., Ill. This is a description of five Canadian peat bogs, with appendices describing the manufacture of peat powder in Sweden, the Aurep peat-machine, and the Ekenberg wet-carbonizing process, followed by a translation of Eleknud's pamphlet, 'A Solution of the Peat Problem.' It is accompanied by maps of the bogs and six plates.

PROCEEDINGS OF THE AUSTRALIAN INSTITUTE OF MINING ENGINEERS. Vol. VIII, No. 1. January 1911. The principal papers of interest in this number are 'A Standard of Adequate Ventilation at Metal Mines,' by F. Reed; 'Precipitation of Gold and Silver in Cyanide Solutions of Carbon,' by R. K. Cowles; 'Estimation of Tin in an Ore,' by R. G. Morgan; 'Metallurgical Processes of the Waihi Grand Junction Gold Co., Ltd,' by A. Fyfe; 'Pumping Machinery for Mines,' by W. Percival Gauvain; 'The Thames-Hauraki Pumping Plant,' by A. C. MacDiarmid; 'Milling and Treatment at the Waihi Mine,' by E. G. Banks; 'Mining Methods at the Waihi Mine,' by J. L. Gilman and W. H. Johnston.

UNITED STATES GEOLOGICAL SURVEY publications recently issued include: 'The Production of Sand-Lime Brick in 1909,' by Jefferson Middleton; 'The Production of Gems and Precious Stones in 1909,' by Douglas B. Sterrett; 'The Production of Abrasive Materials in 1909,' by W. C. Phalen; 'The Production of Borax in 1909,' by Charles G. Yale; 'The Gypsum Industry in 1909,' by Ernest F. Burchard. Bulletin No. 439, 'The Fauna of the Moorefield Shale of Arkansas,' by G. H. Girty. Water-Supply Paper No. 270, 'Surface Water-Supply of the United States, 1909. Part X, The Great Basin,' by E. C. LaRue and F. F. Henshaw. Geologic Atlas. Sewickley Folio, Pa., by M. J. Munn. The topographic maps named below were issued during August, September, October, November, and December 1910: Bath, New York; Briceville, California; Carlyle, Illinois; Clay City, Indiana; Coahoma, Mississippi; Dundee, Mississippi; Eaton, Colorado; Fayetteville, West Virginia; Fort Bayard special, New Mexico; Fowlerville, Michigan; Greenwood Lake, New Jersey-New York*; Hardinville, Illinois; Jonestown, Mississippi; Knights Landing, California; Leadville special, Colorado; Leavenworth, Kansas-Missouri; Lincoln, California; McComb, Oklahoma; McConnellsville, Ohio; Marcuse, California; Murphysboro, Illinois; New Hope, California; New Kensington, Pennsylvania; Nicolaus, California; Okawville, Illinois; Pikeville special, Tennessee; Princeton, Kentucky; Quincy, Washington; Ramapo, New York-New Jersey; Red Rock, Washington; Roseville, California; Sheridan, California; Southern California; Sutton special, West Virginia; United States base map (a wall map in 3 sheets) without contours, 49 by 76 in.*; Vernon, California; Walnut Lake, Mississippi; Winchester, Washington; Yosemite National Park, adm. map (bound edition). *New editions.

THE GARDNER CRUSHER

The range of material that may be handled to advantage in disintegrators is rapidly widening. Originally machines of this type were used only for soft material, but now hard clinker and cemented gravel are put through them successfully. The applicability of crushers of this type, in connection with jaw crushers and tube-mills, to quartz milling is attracting attention. The Gardner crusher is illustrated in the cut below. The shaft is designed to be driven 1000 to 1200 revolutions per minute, and the movable arms or beaters shown in the figure are made of the best manganese steel. Below them is a perforated plate, and inside the top are ribs of extra hard metal that can be moved down near the beaters in the case of wear. The secret of the high capacity and low repair cost of the machine lies in the fact that the rock is forced to do its own crushing, by making one piece strike another. As explained by the builders, when a stone falls into the apparatus it is seized at once by one of the cranks and broken into pieces. The beaters break the stone while giving way to it, and the chips are immediately caught by the following crank, which acts on them with still greater force. Moreover, under the impulse, the material is thrown against other pieces of the same character, and in the midst of the vortex of iron formed by the cranks a nucleus of matter to be crushed is produced, which is carried along by the centrifugal force, belabored and pounded as in a cyclone. If the material to be crushed offers too much resistance, the cranks, owing to their mobility, turn on their axles, by which they avoid breaking. It is to be observed also that the hammers never strike any part of the crusher. The explanation of the low motive power required by the Gardner crusher in proportion to its high yield, lies in the fact that the cranks act as does a fly-wheel. It is the impact and the friction of one piece of material against the other which does the work. There is no part of the crusher where the material to be crushed can act as a brake.



The makers, the Gardner Crusher Co., 556 West 34th street, New York, give the following table of capacities for crushing cement:

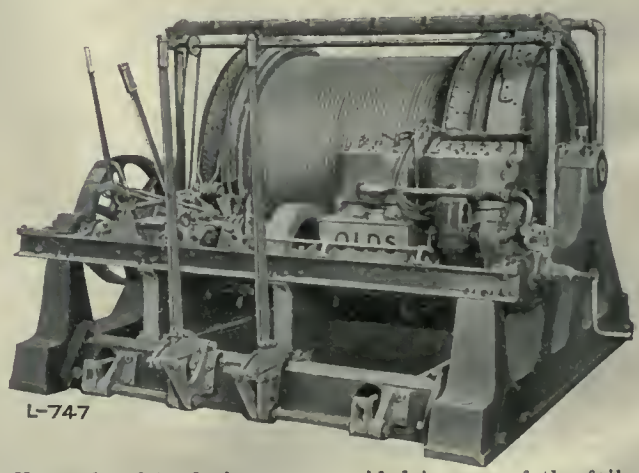
	1	2	3
Feed, inches	4 by 8	6 by 10	10 by 12
Weight	1700 lb.	1½ tons	3 tons
Speed	1000 rev.	900 rev.	800 rev.
Power required	7-10 hp.	12-15 hp.	25-30 hp.
Capacity per hour	3 tons	9 tons	25 tons
Fineness	Everything passing through the 20-mesh screen; about 50% passing through the 100-mesh.		

OLDS GASOLINE MINE HOIST

The engine or power plant of the Olds hoist consists of a multi-cylinder gas-engine of the four-cycle type. The cylinders are cast in pairs, out of the best material that money can buy. These cylinders are annealed to take out all casting strains. Then they are bored and ground to a perfect finish. The pistons are ground into the cylinders, first under auxiliary power, then finished under its own power. The crank-shaft is a hammer forging, with extra large crank and wrist-pin bearings. The valves are of ample dimensions. The carburetor is of perfect design. The ignition system is the 'jump-spark' with both dry batteries and magneto, and two spark-plugs for each cylinder. Ignition troubles are thus positively avoided.

The main working parts of the engine are enclosed in a dust-proof crank-case. Inside the crank-case is a bath of lubricating oil, so all the main working parts are self-lubricated. There is not a single moving part of the engine, except the fly-wheel, that is not protected from dust.

Accessibility to all moving parts for either inspection or repairs is provided. The entire engine can be taken from its frame by the removal of four bolts only, without disturbing another part of the hoist. As no moving part of the engine is exposed, there is no oil flying about, nor is there any condensed steam or water dripping.



Unusual safety devices are provided in case of the failure of the brakes. Two powerful brakes are placed on the winding drum, assuming effective and positive action if everything else about the hoist should fail. One of them can be used as an emergency brake. The clutch lever is operated by hand. When the clutch engages, the engine automatically runs up the speed, and when the clutch is disengaged the engine automatically throttles down to slow speed. At any time after the clutch is engaged, the engineer can throttle the engine by hand to any speed he desires. He cannot, however, make a mistake and run his engine too slow or too fast, as this is governed by a mechanism that operates with the clutch.

The manufacturers claim the maximum of fuel economy and that their hoist is the only one using gasoline for fuel that permits of hoisting different loads at different speeds. The bulletin issued by the makers of this hoist, the Seager Engine Works, Lansing, Michigan, gives a number of testimonials from mining companies.

The Sterlino Lubricator Co., of Rochester, New York, announces the removal of its factory to Norwich, Connecticut, where the shops will be combined with those of the Uncas Specialty Co., the new combination to be known as The Sterling Machine Co. The increased shop capacity and generally improved manufacturing facilities will allow room for expansion and furnish better service for the trade.

The Hodgens-Greene Co. announces the opening of offices at 401-3 State Savings Bank building, Butte, Montana, for the purpose of engaging in general mining and irrigation engineering practice, the exploitation of agricultural and timber lands, mines, irrigation projects, and water-powers, and the management of mining enterprises.

TABLE OF CONTENTS

EDITORIAL

STATE GEOLOGISTS have been meeting at Washington in conference with the Director and other officers of the United States Geological Survey.

ENGINEERS will have large part in the building and conduct of the Panama-Pacific exposition. The choice of Mr. Charles C. Moore to conduct the enterprise is not only excellent in itself, but a compliment to the profession.

OUR excellent contemporary, *The South African Mining Journal*, celebrated its twentieth anniversary on March 18, with a special number of unusual interest. The *Journal* has a record of achievement of which it may well be proud. We extend congratulations and good wishes.

SETTLEMENT of the libel suit of Bayliss *v.* S. Pearson & Son, Ltd., growing out of trouble over management of the Mexico Mines of El Oro, Ltd., has been announced. The defendants disclaimed any intention of making imputations regarding the personal honor or character of Mr. R. T. Bayliss, intending only to criticize his management of the mine. Apology having been offered and accepted, the suit was dismissed.

PORCUPINE will probably be the liveliest gold-mining camp in America this summer. Completion of the railway will make it easily accessible to the great cities of the East, and enough has been done to demonstrate the presence of large quantities of gold ore of a character almost ideal for treatment. It is true that as yet little is known as to the depth to which the ore-shoots extend, but a body 300 feet wide at a depth of 100, and, when carefully sampled, found to assay more than $10 per ton, is itself a sufficient basis for considerable mining activity. Even making allowance for the tendency of decimal points to stray from their proper places, it is clear that much ore of workable grade is present. We print this week a careful description of the deposits, written by Mr. Reginald E. Hore, instructor at the Michigan College of Mines, who is well qualified to discuss the geology of the new district. The boom in Porcupine stocks that started in New York has been temporarily checked. This is not an unmixed evil, since in the list of promoters were the names of nearly all those who did most to discredit Nevada a few years since. Ontario does not need the help of these adventurers, and as for their clients, it may be worth recalling that, while lost woodsmen have often found porcupine meat a savory delicacy, the live animal presents but a prickly exterior to amateur huntsmen.

Zinc Smelting Problems

The metallurgy of zinc is, in many particulars, so peculiar that it can be authoritatively discussed only by a specialist. We have taken pleasure, therefore, in presenting in this, and in our issue of April 15, the review of modern zinc problems that constituted Mr. H. Livingstone Sulman's scholarly address as president of the Institution of Mining and Metallurgy. As befitted the occasion, the review is comprehensive, in that it covers all phases of zinc reduction, and includes summaries of progress throughout the world. In the United States those portions of the address will be read with especial interest that deal with the various flotation processes. Though the principle upon which these processes are based, was discovered at Denver by a schoolmistress while washing sample bags belonging to her brother, an assayer, flotation processes have never been applied on any large scale in the United States. There are undoubtedly large bodies of ore here that can be treated by such processes, but up to the present other means of meeting the situation have been preferred. Such American engineers as have been interested in flotation, Messrs. Hoover, Nutter, and others, have been busy making available the great bodies of zinc residue in Australia. Recently a corporation has been organized to exploit flotation processes in the United States, and doubtless mills will be built in various parts of the country. To a certain extent these processes will come into competition with ore-dressing by means of magnetism and static electricity, but in a broader way the fields are distinct. It is difficult, for example, to think of a flotation plant competing in the Wisconsin field where small units, cheaply built, and requiring the minimum of skilled attention, now operate so successfully. In the Western States where more complex ores occur and gold and silver as well as zinc dust must be taken into account, there is a broader field; and in the West there is much zinc now going to waste. A few years ago the feed of one of the large lead-concentrating plants in a Western State contained within one per cent of as much zinc as would then have rendered the whole operation profitable at Joplin, Missouri, and yet no zinc was saved. Even now there is need, in more than one mill, of a supplementary zinc-saving plant. As Mr. Sulman states, magnetic concentration has usually been applied only to dry ores, and the problems involved in handling wet pulp under magnets are numerous and difficult. As early as 1905, however, at the plant of the United States Zinc Company at Pueblo, Colorado, machines were in use that accomplished this feat. The practice was unusual, and, so far as we are aware, has not been introduced elsewhere. Progress has been rather along the line of better separation of dry ores previously concentrated by ordinary wet processes and improvements in standard methods of zinc smelting. While American spelter-makers have, perhaps, introduced nothing of great novelty, they have made most important improvements so that zinc smelting is no longer far behind other methods of furnace work. The hydraulic-pressed retort is but one of many minor improvements that collectively have raised standards from the old days of hand-fired furnaces with eighty per cent recovery of metal and no by-products, to that in such plants as the Depue works of the Mineral Point Zinc Company. Mr. Sulman's statement of the advantages of briquetting as against charging with ordinary pulverized material is worthy of careful consideration, though at plants where charges are mechanically mixed, and properly dampened and loaded into the retorts, it is entirely possible to satisfactorily treat ores high in lead and iron without briquetting.

Perhaps the most marked development in American methods of handling complex ores is exemplified in such plants as those at Canyon City, Colorado, and in eastern Kansas, where ores are burned with forced draft, the zinc and lead oxides, mixed with some sulphate, being caught in bag-houses and used as a basis of paint, while the cinder left on the grates, and containing copper, gold, and silver, is smelted in ordinary blast-furnaces. The oxide, it is true, is not so well adapted to paint manufacture as is that made at regular oxide plants, but it finds a ready market and the process meets certain situations well. Mr. Sulman mentions Mr. H. Pape's plan of forming an oxide of zinc first and using this in retorts for making spelter. This was done a half-dozen years ago at the Bertha furnace, Pulaski, Virginia, by Mr. J. A. Van Mater. Having on hand a large quantity of calamine tailing containing approximately twenty per cent zinc, Mr. Van Mater burned it to oxide, obtaining thereby an eighty per cent product excellently adapted to sweetening regular furnace charges, and saving many pounds of otherwise worthless material. In a sense he used the oxide furnace for fine concentration, and its possibilities in this direction are perhaps worthy of study. In the Appalachian region flue-dust from the iron blast-furnaces contains much zinc and is regularly saved and sold to zinc smelters. In this there is the germ of a proposed method involving treatment of zinc ores in blast-furnaces, saving the dust, and reducing it in retorts. Whether this will ever be done regularly is uncertain, and the progress being made in direct treatment electrically somewhat reduces the probability. In that connection may be mentioned two papers by Mr. F. T. Snyder that will be read with interest by all concerned with zinc reduction. In the first, on 'The Reliability of Electric Furnaces for Commercial Work', read before the Chicago section of the American Electrochemical Society, January 20, he presented a startling picture of the extent to which electric furnaces have been introduced already in commercial work. The second paper, read at the recent New York meeting of the same society, went into the details of 'The Condensation of Zinc'. That the Canadian commission which is investigating the zinc situation, has in mind the possibilities of electric smelting, is known, and that something feasible in that direction may develop is hoped. In the meantime metallurgists are greatly indebted to Mr. Sulman for his full and fair review of the present situation.

Modern Zinc Problems

By H. Livingstone Sulman

(Continued from page 518)

*The slime problem has been studied by Horwood, who operates by superficially attacking one class of sulphide particle, while leaving the surfaces of the other unaffected, and thereafter submits the product to oil flotation. He usually employs heat to effect this differentiation, a low calcination temperature oxidizing the surface of the galena, while the blende remains unaltered. The Minerals Separation method is preferred for the subsequent differential flotation, owing to its ability to deal with slime mineral. Indeed, a certain proportion of mineral slime is essential to the formation of a coherent froth in this particular oil process. The device of 'deadening' the surface of but one or two different sulphides Horwood has shown may be accomplished by chemical as well as by physical means. His process has been successfully used in certain instances, though the handling of powdery slime in the furnace, maintaining the temperature within the somewhat narrow range permissible, and the consumption of somewhat large quantities of acid in subsequent flotation, are difficulties which at present tend to limit its application. I believe, for example, that it has not been found applicable to the Tasmanian type of ore. Nevertheless, the modification of the surface nature of mineral particles, either in a positive or negative direction in regard to differential flotation, is a principle which is receiving much attention.

It is quite possible that the sphere of usefulness of oil concentration will be considerably enlarged by special preliminary treatments in cases where the raw ore does not lend itself to the direct application of the process. In this connection Dick's process for the treatment of oxidized copper ores must be mentioned. He finds that by heating such material to a comparatively low temperature in a reducing atmosphere, and cooling it in the same, the copper mineral is converted into finely divided metal or into a form capable of ready oiling and flotation. In this simple manner excellent extractions may be obtained on ores hitherto beyond the reach of all but leaching methods, which, owing to local conditions, are frequently incapable of economical application. As so often insisted upon, no process is likely to have a monopoly of employment, even upon a comparatively narrow range of ores, but it may meet special cases with completeness. That under mention will also be watched with interest in its competition with the so-called 'metallizing' process on ores of similar character. Further methods for the proximate separation of minerals require some consideration.

Magnetic separators employing fields of high intensity, and applicable to substances of a low range of magnetic permeability, have still a wide range of usefulness. The Wetherill and Mechernich machines both attained to considerable success in the earlier treatment of Broken Hill middling. I take the following figures from my note-book as showing what was achieved by one of them a few years since. The material to be concentrated contained 29.9% zinc, 8.6% lead, and 12 oz. silver. Two products were obtained: one 44.7% of weight of the whole being a 'leady blende' carrying 36% zinc, 12.9% lead, and 15¼ oz. silver, and the other (20.7%) a blende of 45% zinc, 8.3% lead, and 13 oz. silver. These when mixed yielded a product amounting to 65% of the total, assaying 39.1% zinc, 11.05% lead, and 15 oz. silver. This is equivalent to recoveries of 88.5% zinc, 87% lead, and 81% silver, subject, however, to the usual drawback of a decreased price for the two latter metals. These results have since been exceeded only by oil concentration. Hitherto magnetic separators have been confined to the treatment of dry ore, and however well designed, have always given trouble on account of dust, which is particularly objectionable and dangerous with leady ores. Wet types have been extensively experimented with, and Mr. Ullrich has lately introduced a multipolar ring machine for the treatment of ore pulp. It claims the intensity of field of the older types, and by the application of certain devices overcomes the difficulty of removing small particles from a liquid. Several of these machines are already working, and their possibilities in regard to slime mineral are also receiving close attention.

Electrostatic methods for the separation by electric repulsion of good conductors (such as certain metallic sulphides, pyrite, chalcopyrite, galena, chalcocite, native metals, graphite, magnetite, and hematite) from poor conductors (the silicates, carbonates, oxides, and sulphates—also zincblende) are revived in the Huff machine and process. The first of these processes to be applied in practice was that of Blake and Morscher, in which separation was effected by a revolving electrode energized by direct sparking from a Wimshurst static machine. To these inventors is due the credit of having been the first to introduce a commercial separator on the electrostatic principle. This was followed by Sutton and Steele: in their machine the electrode was charged inductively by a brush discharge, and was furnished with an ingenious interrupter whereby any desired degree of saturation of the separating roller could be obtained to suit the varying electrical capacities of the minerals to be separated. An electrostatic generator was also employed in this type. The main advances in the Huff machine are in the employment of a dynamo-current of suitable intensity, and the discarding of electrostatic generators of the Wimshurst type. The separator is thus capable of adjustment to any required strength of electrical field, and is less liable to interference from climatic conditions. In other particulars it follows previous designs. The limiting factor of electric separators is, so far, their inability to handle fine powders, and their liability to dust trouble unless the dust be first removed.

*Presidential address delivered before the Institution of Mining and Metallurgy, March 22.

After the earlier failures of the centrifugal machine applied to large-scale metallurgical operations, many may have regarded such methods as obsolete, but fresh applications appear possible wherein prominence is given to grading effects little apparent in the shallow basket machine. An interesting apparatus is now on trial. It consists of a long non-perforated cylinder, provided with top feed and bottom discharge devices, the whole rotated from suspension bearings at a high speed. In this elongated drum very marked differences in the classification of particles according to their mass are made, whereby it is claimed that even china clays may be graded with a considerable range and sharpness; even from the best clays it separates some residual mica, otherwise practically impossible, and can also convert portions of inferior clays into products of high class. I have tried it experimentally on other materials and obtained evidence of a good separation. As the grading action depends on length of flow in relation to mass of particle, it is possible that, for some ores, we may have in this appliance the elements of a new machine for slime concentration. Other inventors are still hopeful of the direct concentration of mineral from slime by traveling-belt vanners, and more than one such apparatus is undergoing large-scale trials in England.

In the mechanical treatment of slime, whatever may evolve, we reach the limit of proximate methods of separation. No crushing method of separating one mineral from another with which it is in close physical association can ever be perfect. Whether it be of sulphides from each other, or of either from gangue, the cleavage is always more or less imperfect, as the microscope demonstrates. Even sufficiently separated mineral particles will be likely to retain other chemically combined metals, as silver in blende, for example. This is the departure point of smelting and hydrometallurgical methods, which nevertheless are also subject to their own peculiar limitations. The smelting of complex ore suffers from two main disadvantages: upon the one hand their reduction in the lead-blast furnace is hindered by the presence of an undue amount of zinc, which usually calls for special amounts of flux, and thus is slagged off and lost; and on the other hand, if treated in the zinc distillation furnace, the lead contents cause the destruction of the retorts. The problem has been attacked from both points, and, as is usual, later workers have profited from, instead of being discouraged by, the failures of their predecessors.

Dealing with the former method, H. Pape's reduction of low-grade zinc-lead ores in Germany should be noticed. This consists of smelting them in the blast-furnace with sufficient low-grade silicious ore to slag off the zinc as silicate and recover the lead as metal. The slags are crushed and briquetted with sufficient carbon (together with a binding agent) to effect not only the complete reduction of zinc as metal, but to furnish sufficient heat in the subsequent 'blowing' operation to keep the material molten during the last stages of oxidation. This elimination of the zinc, similar in effect to the New Jersey treatment of franklinite ore, is conducted in a blowing furnace fitted with a special grate, upon which the briquettes are charged to a depth of three or four feet. Upon ignition, a low-pressure air-blast is applied beneath the grate, and the zinc, first reduced by carbon, is blown off and recovered as oxide; the separation proceeds almost to completeness, while the depleted molten slag is discharged through the grate. The zinc oxide is collected in chambers and bag-house plant, the better quality being sold for paint, the poorer to the zinc smelter for reduction to spelter. Nearly 10,000 tons of metal is reported to have been thus produced, and 42,000 tons of zinc slag, as well as low-grade ore, has been treated so in 1910. Zinc residues from spelter production should be amenable to a similar process, large-scale trials having demonstrated the possibility of their profitable handling by such methods when varied in certain details to suit the material. In complex ore-treatment processes, depending upon the prior removal of zinc by distillation, comparatively little progress had been made, if we except electric smelting methods.

It is customary among smelters of other metals to speak of the metallurgy of zinc as behind-hand and lacking in the care and completeness which characterizes their own practice. This reproach is unmerited, as the conditions of reduction of zinc oxide to metal are difficult and peculiar, and the reactions involved highly endothermic. The ore charges, necessarily kept in the condition of rough powders throughout the operations, are very poor conductors of heat, and the production of metal therefrom implies the continued pumping in of heat energy. This imposes a maximum charge thickness of about 8 in., a 24-hour reduction period (from charging to recharging), the provision of small-sized retorts of special construction and with only six weeks life, and in general the handling of large quantities of raw material in very small units. Finally, as it does not pay to carry the extraction of the spelter below a certain limit, the 'seconds' are thrown away, still carrying several units of zinc. Nevertheless, the recovery of metal, upon the whole, is remarkably good. In modern German and Belgian practice a 90% yield of spelter is maintained with roasted blende carrying 50% zinc. Lead recoveries, until the advent of the Huntington-Heberlein process, and others, did not greatly exceed this standard of recovery.

It must be remembered that in the metallurgy of zinc only two operations are required to yield marketable metal—roasting and distillation. When compared, for example, with the various operations in copper practice, involving roasting, sintering of fine, blast-furnace treatment, converting and electrolytic refining, its simplicity partly atones for other disadvantages. Unfortunately, English zinc smelters can not claim equality with the better Continental or American practice, 85% being nearer the usual recovery of spelter here; conservatism, and perhaps undue jealousy in regard to local experience, are responsible for this. The hydraulic-pressed retort, so invariably used abroad, has yet gained but little popularity in this country, where the heavier hand-

made and more expensive article is still the rule. Although gas-fired furnaces are completely replacing the older Welsh-Belgian type, much remains to be done to bring our practice up to the level attained in Continental centres. With a few notable exceptions, a spelter works in Wales is but too often only a revelation of the good work which can still be done with old-fashioned and badly conditioned plants.

The conservatism of zinc distillers seems to be indicated in the indifference of the smelter to 'briquetting' as opposed to 'loose charging' methods. Those who have had experience with the former would not willingly return to the latter, notwithstanding the increased working cost of from 1s. 6d. to 2s. per ton of material briquetted, and the cost of installation. The advantages are pronounced. A furnace will take from 50 to 75% more ore than when loose-charged, all other distillation costs remaining the same, while charging and discharging operations are more rapid and cleanly. The retort will normally take a full charge owing to the greatly reduced slagging, and to the fact that any slag which may accumulate from one charge must be scraped out before a fresh well-fitting briquette charge can be introduced, instead of being allowed to accumulate, as is too often the case with loose-charging. In addition, leady and irony zinc ores, after roasting and briquetting, can be distilled with the same ease as good zincblende material, as no damage to the retorts results from lead, which remains suspended as prills throughout the coked briquette. In loose-charging, the lead sinks through the powdery charge, especially during the 'stirring out' of the residues, and becomes oxidized to highly corrosive litharge during the interval between discharging and charging. The briquetted residues, containing all the lead and silver, are available to the smelter in convenient form.

In the distillation of briquetted lead-zinc ore, a further point of interest is the freedom from lead of the resulting zinc; spelter of 99.5% purity is readily obtainable from complex ore, whereas that from ordinary blendes, distilled by the almost universally practised loose charging method, generally carries from 1 to 1½% of lead. The volatility of lead in zinc vapor is pronounced, but it may be separated to a considerable extent by the filtration of the metallic vapors through a porous medium. This fact has been utilized by Hopkins, who has successfully used a carbon or coke plug between the retort and condenser pipe. It was assumed that the hot carbon stopper exercised some peculiar chemical or physical effect upon the lead; but porous septa of the inert material have since been claimed to possess the same function by other inventors. In the briquetting process the filtration is exercised in the pores of the briquette itself. Under conditions of forced oxidation, such as in the blast-furnace or blowing hearth, lead is as freely volatilized in the form of oxide as is zinc. In the cupola treatment of certain low-grade products containing 11% of zinc and 6% of lead, I have volatilized all the lead while eliminating nine-tenths of the zinc.

In Germany the blowing of oxidized low-grade zinc-lead ores has been practised, a bag-house plant being employed to collect the mixed oxide fume; this was when treated with sulphuric acid for the production of crystallized zinc sulphate, the residual lead sulphate being sold to the smelter. The use of a special type of blast-furnace and the employment of different methods for effecting the separation of the mixed oxides blown off also constituted the central idea of Ellershausen's method; one which, like Asheroft's, very nearly achieved success in the treatment of complex ores.

A marked feature of the zinc industry is its limitation to comparatively few smelting centres. Belgium, Westphalia, and Silesia on the Continent, Swansea in Wales, Kansas, Illinois, and New Jersey in the United States are the seats of the principal zinc reduction operations of the world; and to one or other of these practically all zinc ores are shipped for treatment. Two small plates are installed at Cockle Creek and Port Pirie in Australia, but these can not be said to be effective in view of the large amounts of zinc concentrate now shipped to Europe from Broken Hill, and I am unaware that any great extension of zinc smelting in the southern continent is contemplated. This localization is due to the necessity for cheap fuel, and to the occurrence of the peculiar clays required for retorts; climatic conditions must be suited to the trying conditions of the worker, and above all, the necessary skilled labor must be available. It has been found very difficult to install zinc distillation works without close regard to these limiting factors; in regard to labor especially, it takes many years to train the workers, whose skill and practical knowledge may be said to result from environment, and, in this branch of operative metallurgy, becomes almost hereditary. The failure of one of these conditions may bring about local changes in the industry, as in the case of the gradual failure of the natural gas supply in the Kansas gas belt, and the closing down of many spelter works situated there; only about two per cent of natural-gas-fired furnaces survive, the industry having gradually migrated to the coalfields of Illinois, or to Joplin.

In Australia the labor difficulty is pronounced because of the immigration restrictions imposed on skilled imported labor, and because of the somewhat trying climate conditions of heat and dryness. The cost of distillation naturally varies with the output of spelter. In the larger installations in South Wales £3 per ton of spelter produced may be taken as the cost, including the calcining of the ore. As the latter charge is usually 7s. 6d. per ton, over 15s. per ton of spelter, allowing for unrecovered zinc, is required for this item alone. The actual reduction operation, inclusive of fuel, labor, retorts, etc., will therefore amount to about 40s. per ton of metal produced. But this figure must be increased by the value of the metal lost in the operation, and this is implied in the deduction by the smelter of 8 units from the zinc tenor in the purchase of such ore; this is equivalent to about 35s. Thus 75s. in lost metal value and working cost is incurred in the reduction of one ton of spelter from oxidized ore by

distillation as that process is now practised there.

The 'ultimate' or leaching method of treating complex ores, consisting in the extraction by a solvent of zinc oxide from material containing it, was first practised on an extended scale by Asheroft, at Broken Hill. His failure must be regarded as only antedating certain success along such lines, and metallurgists owe him a greater debt than is sometimes recognized. The difficulties he encountered have in large degree been overcome by later methods; the more immediate cause of his non-success, the production of electrolytic zinc from its sulphate solution, is so far overcome as to form the basis of recent methods; those of Laszczynski and Bradley & Williams will be briefly referred to later. Others avoid the necessity for electrolysis by precipitating the dissolved zinc in such a manner as to obtain a product for the zinc smelter. Typical of such procedure is the zinc bisulphite process, designed to meet the requirements of complex ores which are incapable of reduction by proximate means, wherein roasted ore is submitted to extraction in suitable apparatus by water and sulphur dioxide gas, the latter being derived from the ore during the roasting operation, the zinc is dissolved as bisulphite and separated from the residues which contain the lead-silver, and are sold to the smelter. From the solution the zinc is thrown down as insoluble monosulphite by the removal of one of the equivalents of sulphurous acid; the filtered precipitate, on light muffle calcination, parts with the second equivalent, yielding a dense oxide suitable for spelter production. The eliminated sulphur dioxide is added to the calciner gases, enriching them for fresh leaching work. In this method the ore by aid of water and fuel, furnishes its own extraction reagents, without the interposition of the sulphuric-acid chamber. The sulphate of zinc, simultaneously produced to a certain extent, is allowed to accumulate in the liquor until strong enough for recovery by crystallization. This affords another example of the widened channels for by-product utilization which are continually arising. A short time since it was an established dictum that to leach out zinc in the form of sulphate was to court almost insuperable difficulty, as owing to the limited market for this salt it required conversion to oxide, at a prohibitive cost. The growing demand for white pigments free from lead has changed this, zinc sulphate now largely required for the production of 'lithopone'; indeed the unit of zinc in crystalline sulphate has a considerably higher market value at present than a unit in the form of oxide for smelting purposes.

Although chemical methods have their own difficulties, due to secondary reactions (such as the formation of certain amounts of insoluble zinc ferrite during roasting, whereby complete extraction of the metal is impossible), and are in general somewhat more expensive than proximate methods, they have the great advantage of gathering all the lead, silver, and copper which may exist in the ore into a single smelting product in which these metals are paid for according to the usual scale. Further, the multiplicity of products of varying metal tenor as well as the decreased payment for some of these, is avoided. The initial cost of ore roasting is also offset to a large extent by shipping to the smelter a fully oxidized product, thus dispensing with the preliminary roast of sulphide concentrates otherwise necessary.

A further means for the reduction of zinc sulphate is provided by electrolysis, the deposited zinc being stripped from the cathode and re-melted into spelter, usually of high quality, while the acid regenerated at the anode is used for leaching fresh oxidized zinc from roasted ore, or other product, furnishing a further batch of zinc sulphate liquor. The Bradley-Williams process has been developed in England, that of Laszczynski in Austria and Sweden. Both processes are also available for copper. The careful purification of the liquors is an important factor in either case, as the oxidation of ferrous and manganous salts in the electrolyte to persalts at the anode, causes partial re-solution of the deposited zinc, with consequent loss in efficiency. The bagged anode of Laszczynski's device to a large extent prevents this oxidation, and does not demand so complete an elimination of manganese and iron. Soluble silica, as experienced previously, is also a source of trouble when sulphuric acid is the leaching solvent. In electrolytic zinc methods efficiency in the use of current requires careful maintenance, as energy is the chief item of expense. The electrolyte must be kept uniform by circulation, and current density suitably regulated to prevent 'treeing' of the electro-deposited zinc. Where blende or complex ore is treated it requires careful calcination to obtain good zinc extraction, and in this respect is subject to conditions common to all zinc-leaching processes involving the employment of acid liquors. Some addition of fresh acid will be commonly required for the saturation of bases other than zinc.

In practice it is found that about 5500 electrical horse-power-hour, as a mean figure, is required to produce one ton of deposited zinc, or, roughly, two-thirds of an electrical horse-power-year. With power at 45 kronar, say 50s., in Sweden, the cost for the electrical production of one ton of zinc is therefore about 33s. for energy, this item amounting to rather under 60% of the total process cost. In England the cost of fuel-generated electric power on the large scale is at least double this; with the unit so supplied the electrical horse-power-year costs about 118s., involving an electric energy cost of £3 15s. per ton of electrolytic zinc, to which labor and working costs, remelting charges, etc., must be added. While, therefore, localities favored with cheap water-power will hold an advantage in the production of electrolytic zinc, if plant for the latter be installed at existing zinc reduction centres, dependent upon fuel-generated energy, the balance sheet apparently would still be in favor of the distillation process, despite its poorer recovery in metal. A disadvantage of the electrolytic process lies in the extensive plant demanded, while constant attention of its many units is needed to prevent undue leakage of current. Close supervision is thus called for.

The comparison of the two methods is, however,

not strictly parallel, as distillation applies at present mainly to normal, rather than complex, ores; whereas electrolytic methods—and leaching processes generally—are designed to deal with material not suited to the former. They thus secure an important advantage in the purchase at low prices of the associated silver, lead, and other metals, and in the subsequent realization of these by sale to the lead smelter at ordinary rates. From a narrower point of view electrolysis methods have also to face the competition of other leaching processes, which yield products other than metallic zinc—lithopone from zinc sulphate, as an example—though such outlets are limited in comparison with spelter. A feature of electrolytic zinc is its extreme purity, 99.9% being readily obtainable. This commands higher prices than ordinary brands of spelter, from £28 to £30 per ton being obtained for remelted cake. Such prices, however, can only be regarded as exceptional, the demand for high quality spelter being limited to the production of the finer ductile brasses, such as are used in the manufacture of solid-drawn cartridge cases, etc., and constituting only a small fraction of the total consumption.

The electric smelting of complex zinc ores is now a matter of widespread interest; the processes of De Laval, at Trolhaettan, and that of Snyder, worked at the Canadian Zinc Co., of Nelson, British Columbia, may be selected as typical and involving the two types of electric furnace: the first named employs the electric arc, and the second slag resistance, as means for converting electric energy into heat. Compared with the ordinary retort furnace the utilization of the energy in the electric furnace is high; in the former only about 5% of the total fuel is actually used in spelter production, whereas in the Snyder furnace it is claimed that 75% of the total electric energy supplied is utilized in the reactions, the balance representing the heat of the escaping carbon monoxide and of molten spelter and that lost by radiation conduction, etc. In the arc system the energy is not so fully absorbed in useful work.

In the Snyder process the complex ores are first calcined to oxides, and mixed with the fluxes necessary to form slag with the gangue. Such slags are regulated to a formation temperature of between 1000 and 1100°C. and to a sufficiently high degree of electric resistance: they are of low specific gravity and have no tendency to dissolve zinc oxide. The charge is preheated by the escaping gases which result from the reduction operation. The furnace consists of a double well of molten lead-bullion into which the conductors pass, these wells being electrically connected only by the slag which lies above them, and into which the heated charge is periodically introduced. A layer of carbon is maintained upon the surface of the slag bath whereby it is heated to incandescence. The zinc is volatilized and condensed in suitable chambers, while the lead, silver, etc., sink through the slag into the wells in which the molten metal is maintained at the proper height.

Snyder claims to have smelted pure zinc oxide in such a furnace, for 1050 kilowatt-hours per metric ton of oxide. Mr. Richards has given the heat equation as follows, a kilowatt-hour producing 860 calories:

1050 kilowatt-hours	= 903,000 cal.	
Heat absorbed in reactions	= 687,000	903,000 cal.
Loss of heat in spelter and gases	= 116,000	
Balance, loss in radiation, etc.	= 100,000	

The total electro-thermal loss is 216,000 calories, or 24%, of the electric energy supplied to the furnace. Snyder has laid down the principle that "the heat absorbed in an electric furnace by chemical reactions is electrical energy utilized at an efficiency of 100%. It is only a portion of the sensible heat of the materials treated which is lost by radiation and conduction. These losses should be expressed upon the total energy of the current used after deduction of the heat absorbed in chemical reactions, and not upon the total energy of the current." On the latter basis Mr. Richards quantifies the loss of radiation (100,000 out of 216,000 calories) as 46% of the electro-thermal losses. This is but an alternative method of stating the case, and it seems advisable to point out that there is no utilization of electricity herein for purposes of electrolysis, the energy applied electrically being converted entirely to heat; electrolytic application of the energy would involve greater current consumption than is here shown. It is the carbon admixture which supplies the balance of the energy required. This principle may be said to be equally true as applied to heat generated from fuel.

Notwithstanding the excellent figures demonstrated to be attained, they are conditioned by the cost of the electrical unit: indeed, the limitations imposed in this respect apply as closely to electric smelting as to electrolysis. Electric zinc-smelting may be regarded as a very efficient way of applying a more expensive heat unit, and as permitting a greater concentration or intensity of heat within a narrow area than is attainable by ordinary combustion methods.

RATE OF BURNING OF FUSES

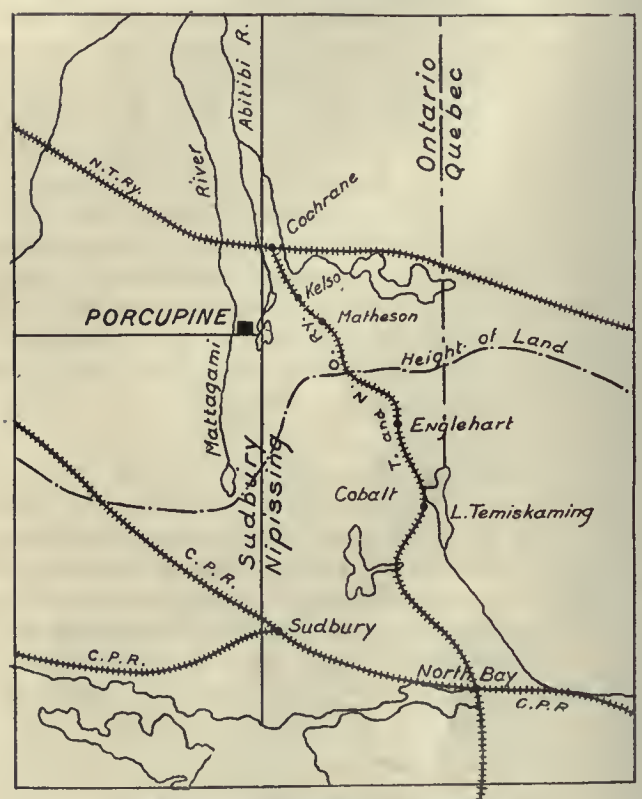
The explosives chemical laboratory of the United States Bureau of Mines at Pittsburg, Pa., is contemplating a study of the influence of temperature and pressure upon the rate of burning of time fuse. It has been found that fuses having a normal rate of burning of 27 seconds per foot may, under the influence of pressure alone, burn as fast as 8 seconds per foot. Conditions of temperature may cause it to burn as slowly as 70 seconds per foot. A centrifugal method has been developed for determining the liability of explosives to exude or 'leak' nitroglycerine from cartridges. Many accidents have occurred from this cause.

Outcrops of manganese ore in a country of precious metal mines should always be carefully prospected, or assayed, for silver and gold, as manganese oxide is often the gossan of a vein of lead-zinc-silver ore, just as a silicious iron outcrop often covers a copper deposit. Such outcrops of black manganese ore are not uncommon in Nevada.

Gold Quartz Deposits of Porcupine, Ontario

By Reginald E. Hore

Gold-quartz deposits discovered in northern Ontario in the summer of 1909, and tested during the past year, have proved to be important. The scene of the discovery is in forest-covered country where low hummocky rock outcrops appear at the southern edge of a vast flat clay belt. Porcupine lake, from which the camp receives its name, having a latitude 48° 30′ is a little farther south than the international boundary between British Columbia and Washington. It is 360 miles north of Toronto, 100 miles northwest of Cobalt, and 200 miles south of Hudson's



Map Shcwing Position of Porcupine.

Bay. The main line of the Temiskaming & Northern Ontario railroad, running from North Bay, the junction of a Toronto branch of the Grand Trunk railway, with the transcontinental line of the Canadian Pacific, to Cochrane, a junction point with another transcontinental railroad now under construction 250 miles farther north, passes 25 miles east of the gold camp. A branch line of this railroad, which is owned and operated by the Ontario Government, is now being constructed into Porcupine, and is expected to reach the lake in June 1911.

The exploration of the deposits, which has up to date proved highly satisfactory, has been carried on under difficulties arising chiefly from lack of summer transportation facilities. Part of the distance from the railroad was readily covered by motor boats on the water-ways; but part had to be negotiated over wet clay roads. It is a country in which level roads are easily found, but the clay stretches, protected by thick forest, and poorly drained, are usually so wet that the summer roads across them have been poor and for heavy loads practically useless.

In winter, however, these roads, if given a reasonable amount of attention, afford a means of transportation unequalled by any wagon-road. During the present winter, therefore, great quantities of supplies are being hauled over the sleigh road from rail at Kelso to the gold camp. The completion of the branch railroad line will settle the transportation problem for some of the mines, while others will have to make but short hauls. With crushed rocks from the mills, the wagon-roads can be much improved. The goldfield is fortunately situated near the Mettagami river, and waterfalls will be utilized to generate power for one mine. The building of a plant is being energetically carried on, and it is expected that the camp will be supplied with electric power early in the summer. For preliminary operations in exploring properties, there is an abundant supply of wood on the claims, and there are numerous small lakes and streams. At Porcupine lake, a shallow body of water two miles long and three quarters of a mile wide, numerous buildings have been erected, and as these include three hotels, visitors can find suitable accommodation there. The trip over the railroad from Kelso to Porcupine takes about six hours. Kelso can be reached twenty-four hours after leaving Toronto.

The most important orebodies which have been developed are those of the Dome and Hollinger mines, both of which are in Tisdale township, but three miles apart. To explore these deposits, machinery and supplies were rushed in on the winter roads a year ago.

At the Dome mine, which is controlled by men who are also interested in the Sudbury nickel deposits, a large quartz mass enclosing much rock but measuring on the surface 200 by 600 ft., has been thoroughly tested to a depth of 60 ft., and explored by drilling to a depth of 400. The ore is white quartz containing native gold associated with pyrite. In places, especially near the wall-rocks or masses of enclosed schists, the gold in coarse grains is readily visible. Most of it is, however, very fine. The microscope shows that in specimens examined, while the gold is closely associated with pyrite, much of it is not in actual contact with pyrite, and only a comparatively small amount is intergrown with the sulphide. The country rocks are gray sericite schist, gray slate, and a schistose conglomerate. All the rocks are impregnated with carbonates—ferrodolomite. Three shafts were sunk and drifts and cross-cuts made at regular intervals on the 60-ft. level. A sample of the ore broken was crushed by a Nissen stamp and passed over an amalgamation plate and a Deister table. The recovery on the plate and table proved the average samples to represent a good grade of ore. There is a large tonnage of ore above the 60-ft. level. Diamond-drilling has proved the existence of good ore to a depth of 400 ft. It is evident, therefore, that there are several hundred thousand tons of quartz and pyritic schists which can be mined and milled at a good profit. The exploration of the ore deposit is now temporarily suspended while operations

are being made for mining and milling. A permanent hoisting shaft is being sunk, and the exploration workings will be used in breaking down the ore. According to a writer in the *Canadian Mining Journal*, a high-grade concentrate is obtained on the table and the tailing warrants cyanidation. Tests show that on re-grinding the concentrate a large percentage of the gold can be recovered by amalgamation. Concentration will therefore be abandoned, and in the experimental tests 48% of the gold has been recovered by amalgamation after two-stage grinding to 90% through a 200-mesh screen. The ore is practically free from cyanicides. Mill-runs of ore at the experimental plant of the Merrill Metallurgical Co. last fall proved so satisfactory that it was decided to build a mill at the property as soon as possible, and the plant has been shipped. Four units of ten stamps each will be erected at once and provision made for later additions. After two-stage preliminary crushing, the ore will be conveyed to the stamps, then pass through 18-mesh screen and over plates, then into classifiers, tube-mills, and over a second set of amalgamating plates. The overflow from hydraulic classifiers goes to Dorr thickeners, and the slime is then agitated in a series of continuous Pachucas. Combined thickeners and storage-tanks will feed to Merrill slime-presses. The gold will be precipitated by the Merrill zinc-dust process.

Hollinger Mine. Shaft No. 1, Stock Pile, and Test Mill.

Stage and Freight Teams on the Road to Porcupine.

On the Porcupine Trail.

At the Hollinger property, part of the holdings of the Timmins-McMartin-Dunlap syndicate, which developed the La Rose mine at Cobalt, there is a system of gold-quartz veins forming part of a veined zone which runs in a northeasterly direction across Tisdale township. Exploration up to date has been confined to the largest of these veins. The ore, like that at the Dome, is white quartz showing native gold associated with pyrite. Some gold is found, as on several other properties in Tisdale township, in coarse particles readily visible to the naked eye. The country rock is a gray sericite schist, chiefly composed of carbonates, sericite, and quartz. The vein has been carefully stripped, and shows more or less continuously for several hundred feet. Three shafts were sunk in the ore. Two of these, 660 ft. apart, have been connected at the 100-ft. level by a tortuous drift following the vein. A winze has been sunk in the vein to the 200-ft. level, and it is said to be in ore as good as that at the surface. According to N. A. Timmins, the vein being worked has averaged 6 to 8 ft. in width; the value has been fairly uniform throughout, the returns from sampling and assaying have averaged $49.80 in gold per ton, while from the Tremaine test-mill the recovery has averaged over $50 per ton, corresponding to a saving of about 85% effected without concentration or effort to treat the sulphides. The Timmins interests are now erecting a 30-stamp mill, and the Hollinger mine will have first claim for treatment. The nature of the secondary processes to be used has not yet been decided. During 1910 the gold production in Porcupine came from the test-mills on this property and the Dome.

At the Vipond property, owned by the Porcupine Gold Mines Co., coarse gold occurs with pyrite in quartz veins in rusty-weathering carbonates, which are in part chloritic. Development during the summer was not extensive, but some rich ore was taken out. During the fall a 2-stamp mill was hauled in over the clay roads and is now in operation.

At the Rea mine, Connell claim, belonging to the Consolidated Gold Fields of South Africa, a white

quartz vein 15 in. to 5 ft. wide has been stripped for over 200 ft., and is now being tested by drilling. It carries free gold associated with pyrite. In places there are rich shoots which show numerous particles of coarse gold, part in comparatively clear quartz, part on and near one wall. The country rock is a light colored rusty-weathering ferrodolomite rock which is apparently an altered hornblende andesite. Near the main quartz vein there are a number of minute quartz veins running into the carbonate.

On the Foster claims, controlled by F. A. Heinze, there is a quartz-ferrodolomite vein which has been exposed continuously for several hundred feet. It shows a remarkable series of quartz veins traversing rusty-weathering carbonates. Coarse gold can be seen in several places in the quartz. The country rock is a gray sericitic carbonate.

Northwest of Porcupine there are a number of deposits which have been explored to more or less extent. Considerable work has been done by the Crown Chartered and Scottish Ontario companies, and more recently by the Tisdale Mining Co. Several important discoveries have been made on adjoining claims, but have not been as yet extensively explored.

The general geological features of the new goldfields are similar to those of well known areas of pre-Cambrian rocks in the Lake Superior district. The ore deposits and their immediate wall-rocks are in many ways remarkably similar to the most common type of gold-quartz deposits in California. The rocks in the immediate vicinity of the gold-quartz veins are of types common in the Keewatin and Huronian formations. The Keewatin rocks, all of which are much metamorphosed, and many schistose, are chiefly altered igneous rocks, mostly volcanic, with a subordinate volume of altered sediments. The Huronian is wholly sedimentary. Most of the important gold discoveries are in members of the Keewatin series.

The most constant feature of the immediate wall-rocks of the veins is the high percentage of carbonates and sericite which they contain. The wall-rocks are usually completely, or almost completely, made up of secondary minerals. The lighter colored rocks are chiefly composed of carbonates, sericite, and quartz, while darker ones contain chlorite and magnetite. In one case, at the Rea mine, a dark colored rock of this type grades into a more distinctly igneous type containing partly altered crystals of plagioclase feldspar and hornblende, and which was probably originally a hornblende andesite. In another case, at the Hollinger mine, the wall-rock is light in color and free from chlorite and magnetite, and was probably originally a light colored siliceous volcanic rock such as the quartz-porphyry which occurs in the vicinity. In a third case, at the Dome mine, there is in addition to altered volcanics, a conglomerate in which the matrix consists largely of carbonates, sericite, and quartz. Other deposits, while showing a variety of rock types, are similarly characterized by an abundance of carbonates in the wall-rocks, and it is probable, therefore, that such carbonates were introduced by solutions which penetrated the fissures later filled with gold-bearing quartz.

The carbonates have been variously designated as ferrodolomite, ferruginous dolomite, dolomite, ankerite, and siderite. Commonly they weather rusty, and the presence of iron is thus evident. In other cases the surface weathered specimens are comparatively free from red stains and the iron content is probably low. None of the available analyses of rusty-weathering carbonates show an iron content as high as in siderite or normal ankerite. For such rocks the term ferrodolomite is here preferred, though the term ankerite has been used for quite similar rocks in some localities, and is in common use in the new camp. The rocks are similar to some which are found in Keewatin rocks in such association with types of sedimentary origin, that the carbonates are believed there to be sedimentary beds also. The wall-rocks of the Porcupine gold deposits are nevertheless believed to be the result of secondary replacement by solutions containing an abundance of potassium, which is now present in sericite, and of carbonates and carbon dioxide.

The various deposits can be grouped from their form into four classes: (1) Single fissure fillings or veins; (2) a series of intricately connected filled fissures forming a vein system; (3) quartz-ferrodolomite lodes in which quartz veins form an intricate network in a band of carbonates; (4) quartz masses of irregular and unknown shape. The veins and vein systems show that extensive crystal movements preceded the deposition of the ores. Evidently there were numerous fissures running more or less continuously for several miles in a northeasterly direction. The extensive fracturing of the rocks was not unlikely accompanied by the movement of igneous material closer to the surface. The wall-rocks were probably altered by and the gold-quartz veins formed from hot solutions which penetrated farther than the main mass of molten magma. Since the crystallization of the quartz it has evidently been subject to severe stress, as the grains are distinctly strained and somewhat granulated. The quartz veins in Tisdale township are younger than any rock exposed there, the fissures cutting Huronian as well as Keewatin rocks. There is little or no evidence that the quartz veins have been formed by replacement. Apparently the carbonate deposited in the wall-rocks previous to the vein formation acted as a barrier preventing the escape of silica into the wall-rocks, except along the minor fissures in the latter. Numerous veinlets of quartz run from the large quartz masses into the carbonated wall-rocks; but the quartz in such cases is very distinctly confined and often separated from the rock by a very finely granular border of carbonates.

The gold occurs in quartz that is usually characterized by pyrite and to a less degree by sericite and calcite. Plagioclase feldspars have been found in the Hollinger vein by C. W. Knight, and in the Vipond by John Stansfield. The quartz is commonly massive. It is generally white, but some veins are of bluish gray color. The quartz is in part of coarse

grains 0.5 to 1 mm., and in part of finer grains 0.05 mm. in diameter. The coarse grains commonly show numerous inclusions, indicating a probable high temperature and complex character for the solution from which it crystallized. It shows marked strain shadows indicating subsequent subjection to deformation stresses. The finer quartz is comparatively free from inclusions and does not show marked effects of strain. It is evidently younger than the coarse. Some of it was probably produced by the re-crystallization under pressure without moving far from its original place. Some evidently was brought in from elsewhere. Gold occurs sometimes completely enclosed in single coarse quartz grains, but is more common otherwise.

Quartz-Ferrodolomite Lode, Foster Mine. A 15-Inch Quartz Vein in Schistose Carbonates.

White Quartz in Gray Schist, Hollinger Mine.

It is most common in specimens showing fine-grained quartz, and is frequently in or in contact with the fine quartz. Gold occurs also in calcite and in pyrite. The pyrite is in part at least as old as the coarse quartz. The calcite, while older than some of the gold, is younger than the coarse quartz. The coarse quartz of the vein is evidently younger than the ferrodolomite in the wall-rock. While the gold-quartz veins have characters which mark them as deposits from hot solutions, such as are given off when a molten magma is intruded near the surface, there is not in the vicinity of the deposits any mass of igneous rock which is likely to have been formed from the same magma. According to W. G. Miller, there are within a few miles of Porcupine large masses of granite which are intrusive into the Huronian. It is possible that these may be genetically connected with the gold deposits. It is interesting here to note that many of the California deposits occur also in metamorphic rocks a few miles from the edge of large masses of granitic rocks.

In view of the above description, it is of interest to quote here some general remarks made by Waldemar Lindgren,* of the United States Geological Survey, on the characteristic features of California gold-quartz veins. The similarity of the Porcupine deposits to them will be evident:

1. "Within the typical gold-bearing region (of California) the veins are distributed with marked impartiality, and occur in almost any of the great variety of rocks which make up the metamorphic series."—A similar statement would be true of the Keewatin series in Tisdale township.

2. "The gangue is quartz, with a smaller amount of calcite: the ores are native gold and small amounts of metallic sulphides."—In Porcupine calcite is very subordinate in the quartz veins, the ore is native gold, free or in pyrite.

3. "Adjoining the veins the wall-rock is usually altered to carbonates and potassium-micas by metasomatic processes."—This can be stated to be quite characteristic at Porcupine also.

4. "The veins have been filled by ascending thermal waters, charged with silica, carbonates, and carbon dioxide."—The same deduction may be drawn from the nature of Porcupine wall-rocks and veins.

5. "The gold-quartz veins of California do not in their surface relations show any remarkable dependence on acid igneous rocks."—It has been pointed out that there are no such rocks in Tisdale township of the same age as the gold deposits. The deposits may, however, be genetically connected with granitic masses, such as are exposed a few miles away, and which underlie the rocks in Tisdale township. An analogy is to be found in the granodiorites of the Sierra Nevadas.

NATURAL-GAS LEAKAGE IN COAL MINES

Two coal mines in West Virginia were recently sampled and analyzed for natural-gas leakage apparently due to a natural-gas well passing through a barrier pillar. Gas was found bubbling up through the water, which, upon examination, corresponded with the natural gas obtained from the well. Samples of mine air vitiated by explosives fired in mines were examined and found to contain in some cases harmful amounts of noxious gases. Samples of natural gas from Nevada were examined, and in one case found to be exceedingly rich in methane.—*U. S. Bureau of Mines.*

A Farncomb Hill Story

By A. J. Hoskin

Probably every well informed American miner or, at any rate, every Western gold miner, has heard about or actually knows something concerning the wonderfully rich, beautiful, and mineralogically interesting native gold specimens taken from fissures in Farncomb hill, in the Breckenridge district, of Colorado. The most interesting period in the history of the working of these veins was some twenty-five or more years ago, but the residents of the region still take much pleasure in their reminiscences of the days when the coveted yellow metal was taken out of the ground 'in chunks.' At the present time, this same region is attracting wide notice because of the successful dredging that is being conducted by several companies. As a rule, the gold that is being recovered from the placers of Breckenridge is comparatively coarse and nuggets ranging up to an inch in length are occasionally found in clean-ups. Various stream channels are being worked in the district, but the finest nuggets are found in those channels that head well up in Farncomb hill. Of course, the coarsest gold is found nearest its original lode source, so that the dredges working in French gulch recover much coarser gold than the boats that operate in the Swan river and the Blue river. The source of the gold now being found so abundantly in the bed of French gulch was undoubtedly quite close at hand and was probably the upper portions of veins which, during rather recent geological times, have been broken down by natural agencies. This gulch is flanked by Farncomb hill, and there can be no question as to the original deposition of the gold in the veins of that famous mountain. Despite the disintegration and erosion which have destroyed and removed a very considerable depth of the original solid structure of this mountain and have converted the upper parts of gold-bearing fissures into constituents of placer ground, some of these same veins were left for the destruction of man. A quarter of a century ago fortunes were quickly made—some of them as quickly dissipated—by humble, but hardy, prospectors who were either successful or 'lucky' in discovering these remarkable orebodies.

Although the presence of such rich auriferous veins was long suspected, these deposits eluded the search of miners for years, since the hills and valleys of the district were clothed quite completely with an abundant covering of 'wash' that rendered an inspection of the rocks in place impossible except at much labor and expense. Accordingly, much credit is due to those prospectors who overcame this natural obstacle by sheer perseverance and the exercise of hard manual labor. At the same time, there is a sort of glamor accompanying any discovery of great moment, even if it be by mere chance, and the lucky men feel a double sort of reward—they get fame as well as riches from their fortunate strokes. The rich Farncomb hill veins were finally uncovered through chance. The residents of Breckenridge delight in telling tales of the adventures of the men who dug the beautiful gold from its matrix in 'chunks' and 'slabs.' There is none of this wonderful mining now, placering having taken the scene of action. This is not stating that there are no more of the wonderful deposits still intact, and it seems strange that greater effort is not exerted, nowadays, to carry on the underground mining that was typical of the years gone by.

In the days mentioned, three miners were working a partnership claim up on the famous hill, almost to the very top, where the covering of soil was thinnest and where, therefore, the excavations necessary to reach bedrock were most shallow. Two of the men were married. One of these married men was fortunate enough to have his wife with him to keep house in a cabin not far from their labors, in the then little but lively camp of Lincoln. The two other men 'batched,' and when at work in their cabin was necessarily left unguarded. This fact led to the practice of all three men pooling their finds and carrying everything of value to the cabin occupied by the lady, there to be left in her custody during the hours when her husband was at his mining labors. Success rewarded the efforts of these hardy prospectors, and they, ere long, were quietly carrying home, each evening, pocketfuls and bucketfuls of the native gold. Such a statement of quantity seems hard to credit; but it seems to be unquestionably true that the fortunate miners of that time did actually 'pack' away the precious metal by the pound. It thus became the duty of this miner's wife to act as guardian of quite an accumulation of gold.

Now it happened that this same woman had, before Fortune's advent, for frugal reasons, put in a small stock of general merchandise, which she kept on sale to the prospectors and miners who could not readily travel the several miles to Breckenridge for supplies. As a still further means of livelihood and as a convenience to her patrons, she also conducted a primitive postoffice. In those same days there roamed over the region, doing desultory prospecting, a man who is still a resident. He will vouch for this story in which he will appear as the star character. One day this man, whom we will call Jack for short, drifted into the cabin store, as was his frequent habit, just to "rest a bit and to inquire for mail." This particular day, however, stands out clearly in his memory. It was upon this occasion that he learned for the first time of the three prospectors' good fortune. The lady in charge had inadvertently left the door of her cook-stove open and the caller's gaze became riveted upon an ordinary bread-pan within the oven. In order to thoroughly dry the quartz and other gangue brought home with the native gold and thus render possible its pulverization in an ordinary mortar and pestle, it was the lady's duty to occasionally make this moisture run. The men would subsequently complete the separation by crushing and panning. While this appears now to have been a very crude scheme, it was, nevertheless, an effective one. On this particular day, the bread-pan was overflowing with the tempting masses of beautiful gold. An overwhelming covetousness instantly seized Jack. He shortly withdrew to

concoct a scheme whereby he might, without resort to force, become the possessor of at least a part of this treasure in the oven. Cogitation soon conceived a fictitious, sudden, but powerful attack of bowel derangement which he might relieve by the taking of doses from the bottle of patent medicine that he recalled having noticed upon a top shelf on the opposite side of the room from the stove.

Returning to the store and simulating the symptoms of colic, Jack requested the lady to sell him the remedy, at the same time excusing himself from gallantly climbing up for the bottle on the plea of his distressing ailment. The proprietress therefore laboriously placed a chair and a table in position and clambered up. While she was thus busy in securing the package from the shelf and was necessarily standing with her back turned toward the room, the man quickly reached into the oven and deftly accomplished his pre-arranged theft of one of the largest nuggets which lay on the surface of the panful of gold. The clever scheme worked out precisely as he planned and he was now the possessor of a beautiful treasure. It being mid-summer, this mountaineer wore rather scanty clothing, especially during the middle of the day when he was wont to do his tramping and climbing. Upon his trips, he found comfort in the simple apparel of hat, shirt, trousers, and footwear, the shirt, furthermore, being open at the chest. Excitement immediately followed the possession of the nugget. As is frequently the case in questionable dealings, this proposition turned out to be a 'hot one.' The gold nugget was actually quite hot, too much so for comfortable handling. At such times as this, persons who have had absolutely no premonition of impending necessity often do very original and dexterous feats. In his emergency, therefore, this man instantly dropped his heated acquisition into the opening of his flannel shirt, whence it immediately gravitated to a stable horizon just above his belt-line. Probably for the first time in his life he now appreciated the fact that the skin on one's palm is considerably more fire-proof than is that of one's abdomen. The gold cure has become famous as a treatment for the liquor habit, but this man established the effectiveness of an external application of the metal as a sure cure for bowel complaint. Whether or not the gold really exerted any magical effect, Jack's ailment of the minute before had vanished. Having no further need or desire for the bottled remedy—and possibly to avoid spending his hard-earned money for something he did not need—he very unceremoniously bade his lady friend adieu by yelling as he flew through the door, "I can't wait. I don't want it."

A minute or two later, his hasty exit was fully explained in the lady's mind, for she noted the absence of some of her batch of baking. Just then gold nuggets were rather plentiful at this small establishment, while good jokes were more rare. So it was a jolly party that discussed the day's happenings in the store that evening. It was generally agreed that the visitor had received fair punishment for his crime, and nothing was ever done toward the enforcement of a legal penalty.

PLACERS IN CALIFORNIA AND ARIZONA

There are few placers in either California or Arizona that are not known and claimed. There are large areas in California still unworked, but these are mostly in the arid regions of Mojave and Colorado deserts. Some important instances are the dry placers at Summit, north of Randsburg, in Kern county, and extending southwesterly to Goler and Garlock. There are placers 2 miles north of Randsburg. In fact, the entire desert wash of that region contains gold which in some localities has been concentrated by winds and rain to a condition of payable ground. Another locality is that 10 miles north of Barstow where a large area of gravel is gold bearing. In the Colorado desert gold is found in the wash in the Cargo Muchacho mountains, 15 miles north of Yuma; at Picacho basin, on the Colorado river; in the Monte Negras, 45 miles northeast of Thermal, and at numerous other places. It is needless to say, however, that every place known to contain gold in payable quantities has been or is being worked. The same may be said of Arizona. Extensive placers occur in the valleys of both the Colorado and Gila rivers. One locality is near the Gila, 20 miles above its confluence with the Colorado. In the valley of the Colorado, placers are known from the vicinity of Yuma up the river to above Ahrenberg. In the vicinity of the latter town is cemented gold-bearing gravel, which has never been profitably worked because of the indurated character of the ground. Modern disintegrating and dry-washing machinery will overcome the mechanical difficulties. The difficulty is to find a spot sufficiently rich to pay. In central Arizona placers have been worked since 1860 and a large amount of gold obtained. The region covers southern Yavapai, northern Maricopa, and a good portion of Yuma county. It is possible that many good places remain unworked, but have been too poor to pay by the slow, small-scale, primitive methods of the earlier days. To such areas modern methods and machinery must be applied. There are doubtless many places where profit would result from the intelligent application of capital and energy, but these favored places must be sought out by actual trial.

Mining costs vary with the nature of the deposit; its geographical position controlling costs of supplies, labor, etc., and the personal equation of management. Magnetic separation costs vary directly according as the crude ore is easy or difficult of comminution preparatory to separation, and inversely as the amount of magnetic oxide contained in the ore. The actual separation process costs but a few cents per ton.

A good substitute in place of glue or various kinds of cement for fastening emery cloth to the disks of grinders is to heat or warm the disk and apply a thin coating of beeswax; then put the emery cloth in place and allow to set and cool under pressure.

Economy in Drill Steel

By G. E. Wolcott

There is no single item in connection with the economical breaking of rock with dynamite, of more importance than the quality of the cutting tool em-

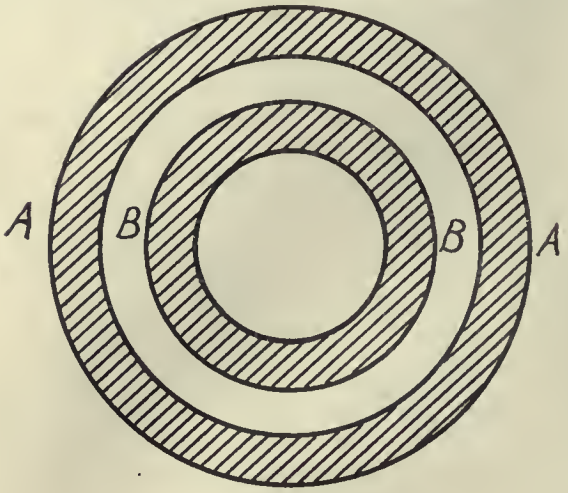

Fig. 1.

ployed in drilling. The best machine will accomplish indifferent results with poor steel. With poor cutting tools there is a loss due to higher power consumption for a given amount of drilling, a loss in

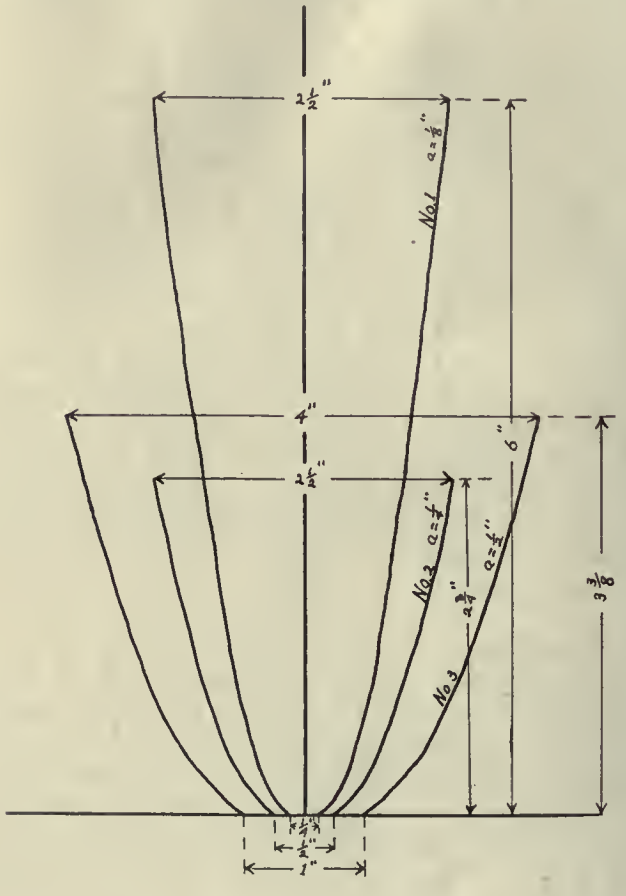

Fig. 2.

time of high-priced labor, and a further loss because of the necessity for more frequent renewal of the bits. The initial cost of drill steel is of little importance as compared with its quality and the shape and quality of the cutting bit formed upon it.

If a piece of steel 3 ft. in length weighs 10 lb. and costs 10c. per pound the initial cost will be $1. If during a year's use it is sharpened on an average once every two days, and the sharpening costs 5c. per bit, the steel will have cost $9.10 during the year for sharpening alone. A steel costing 40c. per pound will be cheaper at the end of the year if the amount of sharpening it receives is reduced by one-half. If the increased drilling efficiency due to a more resistant bit be taken into consideration, it is no exaggeration to say that a steel costing $1 may be cheaper than one costing but 10c. per pound.

The development of the air-hammer machines during the past few years and the tendency of these

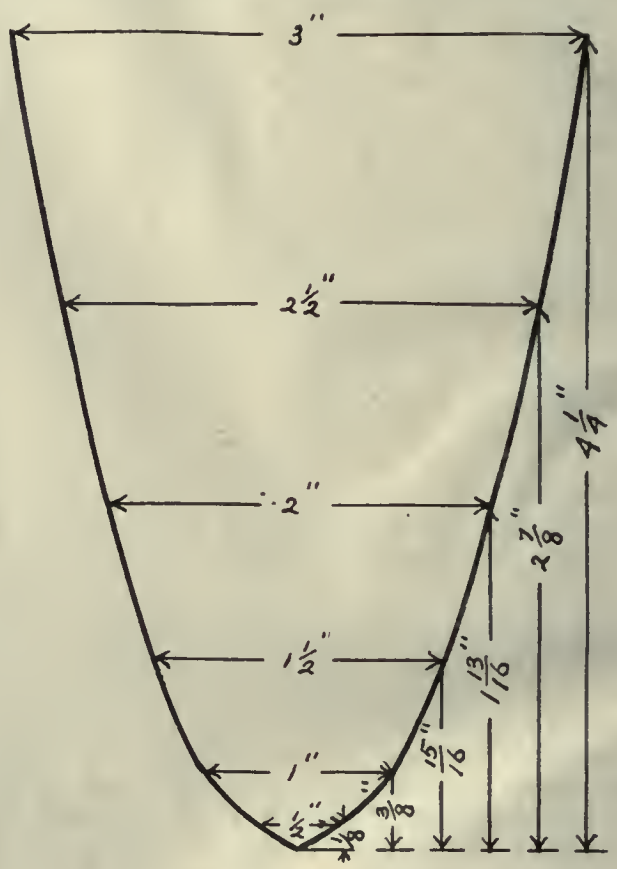

Fig. 3.

machines to break steel, has led to the manufacture of special brands to meet the more exacting demands. Of these, vanadium steel seems to be giving most satisfactory results and is now being manufactured at a cost not much greater than ordinary steels. It is quite probable that the next few years will see this steel used almost exclusively for rock-drilling purposes.

The arguments above presented are of equal force when applied to the proper shaping and tempering of the bit. The best of steel can not do satisfactory work when poorly sharpened, and too much stress can hardly be laid on the proper shape of the cutting bit. It is the purpose of this article to bring out certain points in this connection that, so far as I know, have heretofore received little consideration.

In the cutting of a round hole by a rotating bit, the amount of material to be cut by a certain portion of the bit will increase going away from the centre of rotation. For this reason the cutting edge of a bit having a square face will always dull first at the outer corners. In Fig. 1 if *A A* and *B B* represent

two annular segments or portions of rock to be cut, and the width of these segments is the same, then the area of the segments will vary directly as the distance from the centre of rotation. It follows from this that if a bit is so made as to dull equally over its whole cutting edge the number of edges or their lengths must increase in direct proportion to the distance from the centre. In practice it is not practical to increase the number of cutting edges, but the length of the cutting edge may be made in direct conformity to this rule. A steel so sharpened will dull equally over its whole face and will stay sharp longer than any other shape. The exact shape of the bit will be a logarithmic curve, the equation of which has been deduced by C. C. Van Nuys of the

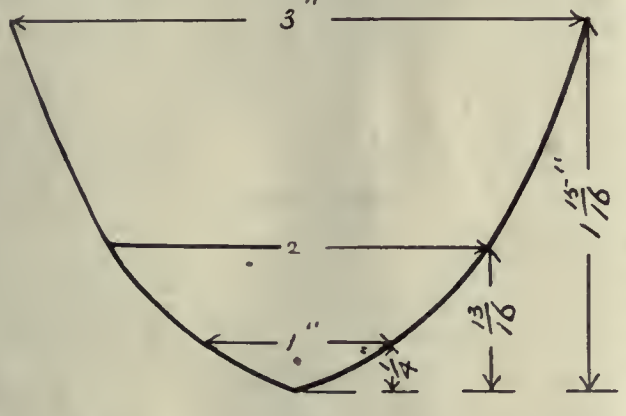

Fig. 4.

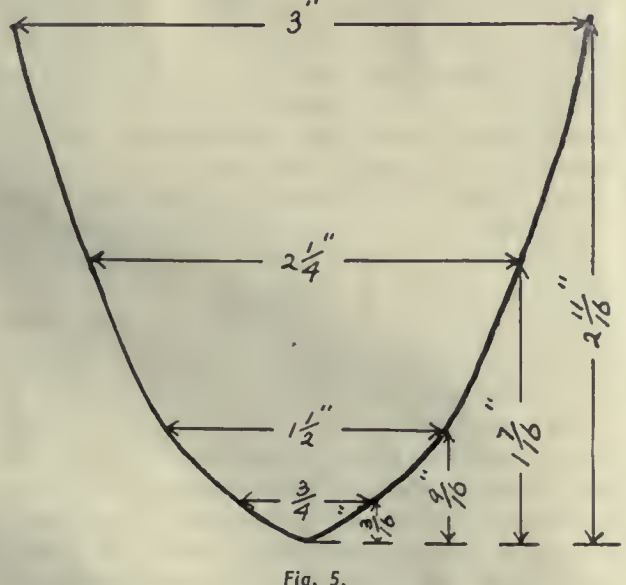

Fig. 5.

South Dakota School of Mines. The derivation of the curve involves the use of integral calculus and will not be given here. Its equation is

$$y = \frac{x}{2a}\sqrt{x^2 - a^2} - \frac{a}{2}\log_e\left(x + \sqrt{x^2 - a^2}\right) + c$$

In this equation x cannot have a value less than a, so that a is the point of nearest approach to the y axis. The y axis is here taken as the centre of the rotating bit and the x axis as passing through the point nearest the y axis. By assuming a value of 1 for a the above equation is simplified to the form

$$y = \frac{x}{2}\sqrt{x^2 - 1} - \tfrac{1}{2}\log_e\left(x + \sqrt{x^2 - 1}\right)$$

By assuming 1 as a unit of one-fourth, one-half, or any desired portion of an inch or any unit of measure we may plot any desired curve from this equation which will answer the requirement that its length vary as its distance from the y axis. The condition cannot be fulfilled for any point nearer the y axis than the unit taken.

Fig. 2, on the opposite page, shows three curves plotted from this equation by assuming values to a of ⅛ in., ¼ in., and ½ in, respectively. A bit having the shape of curve No. 1 would stay sharp longer than either No. 2 or No. 3, but would not be a practical shape, as its extreme length would cause it to break readily at the point. Fig. 3 shows the dimensions of a bit up to a width of 3 in. when a is taken as ¼ in., and Fig. 4 shows the dimensions with a taken as ½ in. In both cases the shape of the bit near the point must be assumed and can only be approximately correct.

For practical purposes the shape of a bit will hardly be more pointed than that shown in Fig. 3 or more blunt than shown in Fig. 4. Fig. 5 shows an intermediate shape plotted by assuming $a = \frac{3}{8}$ in. In all of these figures the measurements given are correct to within $^1/_{16}$ in. In each a may be considered as the modulus of the curve and upon its value will depend the relative width and length of the bit. Any desired curve may be plotted from the following value of x and y, and in any of them the condition is met that the length of the curve is proportional to the distance from the y axis. The shape of the curve must be assumed for values of x less than a.

When	$x =$	1 $\times a$	$y =$	0
	$x =$	1½ $\times a$	$y =$	0.526 $\times a$
	$x =$	2 $\times a$	$y =$	1.073 $\times a$
	$x =$	3 $\times a$	$y =$	3.361 $\times a$
	$x =$	4 $\times a$	$y =$	6.685 $\times a$
	$x =$	5 $\times a$	$y =$	11.101 $\times a$
	$x =$	6 $\times a$	$y =$	16.50 $\times a$
	$x =$	10 $\times a$	$y =$	48.25 $\times a$
	$x =$	20 $\times a$	$y =$	197.9 $\times a$

A bit shaped according to the curve discussed above will stay sharp, except for breakage, longer than for any other shape having an equal length of cutting edge. As compared with a square bit it will turn more easily in a hole when used with an air-hammer machine. Whether used with an air-hammer or piston machine it will cross a slip, as a rule, more readily than a square bit. This is due to the fact that there is less tendency to break the cutting edge and to the fact that there is a longer surface in contact with the rock on the side away from the slip, which prevents the steel from being forced out of line.

In the development of the air-hammer machines a bit has been used which approximates the shape given from plotting the above curve. The object sought has been to make a steel that would turn more readily in the hole; incidentally it has been found that it stays sharp longer and that it crosses a slip more readily. I well remember one mine superintendent making the remark that the high centred bit was theoretically all wrong, but that it was practically all right. The above discussion seems to show that it is both practically and theoretically correct.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Re-grinding Sand

The Editor:

Sir—I should be pleased if any of the readers of the *Mining and Scientific Press* would furnish data as to the tonnage of sand (that is, ore crushed in a stamp battery through 30-mesh screens, and the slime removed) that can be ground to pass 150 mesh in 24 hours by a Wheeler grinding pan five feet in diameter. Also I would like to know the horse-power required to do the work. There exists here a great diversity of opinion as to the performance of the ordinary grinding pan such as is in common use in Australia and elsewhere.

Tank Versus Vat

The Editor:

Sir—With regard to an item in your April 1 number bearing the above heading and signed KCN, I wish to acknowledge my appreciation of KCN's sense of humor, in timing that article to appear on the first day of April: there is no doubt that it is an excellent joke, for I have heard several good laughs over it. I think it is common practice in all business, whether cyanide operations or anything else, to be as concise as possible. So when we learn that in a cyanide plant a tank for holding sand during treatment, is a vat, naturally we begin to call it so, rather than take a round-about way of saying what we mean. A cyanide tank might refer to nearly any tank in the mill, but I think that without any further qualification it would be understood to mean a tank for the storage of barren solutions, and not a gold sump, an agitator, or a sand vat.

BYRON L. EASTMAN.

Grass Valley, California, April 2.

The Clancy Process

The Editor:

Sir—It will be seen from reading D. Mosher's article on the Clancy Process published in your issue of March 25 that there is no ground for the comments and figures which he has given. If Mr. Mosher wants cheap cyanide and thinks he has it in calcium cyanide, it has nothing to do with my process. I do not use calcium cyanide nor do I attempt to produce calcium cyanide from cyanamide. In all cyanide plants using lime, surely a certain amount of calcium cyanide may be formed. Would Mr. Mosher then attempt to restrict the use of lime in the cyanide process unless he is paid a royalty? That Mr. Mosher has shown in his writings that he does not use cyanamide or calcium cyanamide, may be seen from the disparaging manner in which he speaks of my use of cyanamide in conjunction with the cyanide solution. He states that he can not see any value in the use of cyanamide other than protecting the cyanide through reducing the cyanate by means of the NH_2 group present in the cyanamide, and forgets that when I use oxidation means other than the atmospheric oxygen, a considerable proportion of cyanate may be formed in the solutions. If this destruction of cyanide to cyanate can be prevented by the use of cheap cyanamide in presence of sulphocyanides is it not a consummation devoutly to be desired? To demonstrate that Mr. Mosher has not caught even a glimpse of the claims of my process, suffice it to insert a quotation from his article and leave the rest with the readers: "Unless Mr. Clancy has found some special effect in the use of cyanamide in his researches, I can only see a slight commercial value in its adoption in cyanide treatment."

JOHN COLLINS CLANCY.

Ore in Sight

The Editor:

Sir—I have read with great interest C. S. Herzig's article on 'Ore in Sight,' in the *Mining and Scientific Press* of February 18, and hope that his suggestions on methods used in estimating 'reserve ore' may be of as much benefit to many engineers as they are of especial interest to me.

The paragraphs which especially occupied my attention related to sampling and ore-reserve estimates. Methods of engineers who have insisted on the 'ore opened and sampled on three sides' rule of thumb, without taking any consideration of the past record of the property in question, size of vein, quality of the 'raisins' extracted, geological deductions, and exceptional facilities for exceptionally low operating expenses, have worked against the interest of certain of my friends.

To be concise, I cite a mine from which probably $300,000 was taken prior to purchase by Eastern men, about $150,000 having been recovered, but records and hearsay indicated that the ore stoped 'plated' about $6. Operating for the Eastern company, crushing some 11,000 tons through 30 mesh, I ascertained the concentrate to average 3%, and recovered on plates average of $3.48 for total tonnage. In doing this all quartz broken passed through the mill, all development rock from drifts and raises, and only 312 cars were dumped as waste during 30 months. The pay-ore occurs as lenses, irregular but massive, assays above $7 in such lenses, the greatest horizontal distance between being 125 ft., greatest vertical distance 26 ft., width of vein in lenses 10 to 20 ft., width between lenses averages 8 ft., value about $3 by assay. There was recovered by amalgamation possibly 50% of the ore value, due to many causes, principally lack of funds and equipment, and being forced to operate with mill of the type of 1872. Several engineers who examined this property have simply shrugged their shoulders because the "raisins have been extracted," and the vein presents today low-grade ore on the border of such 'raisins.' No consideration was given to ore overhead above

the raisins, though opened 700 ft. long and 400 to 500 ft. up to the surface, because there were no raises through to the surface, and this ore was only opened on two sides. The entire surface of all claims is covered with dense and heavy timber, all machinery operated by unfailing water-power, purchased at 10c. per inch, under 800-ft. vertical head. Why are some engineers so dense; is it, as you remark, the human factor?

J. D. WHITNEY.

Red Bluff, California, February 20.

Cost of a Shaft

The Editor:

Sir—I, together with many other readers of the *Mining and Scientific Press*, will be greatly obliged for information regarding the following: Average cost per cubic foot of hoisting from a shaft of any depth from the surface to 150 ft., wages $3.50 per day. The hoisting is to be done with a horse-whim. Cost of keeping horse $1.50 per day. The shaft is to be 4 by 8 ft. in the clear. What will be the average cost of labor for timbering such shaft, including guides and ladders, timbers 6 by 6 in., 5-ft. centres, lagging 2-in. plank? Also give a good cheap method for framing timbers for such shaft.

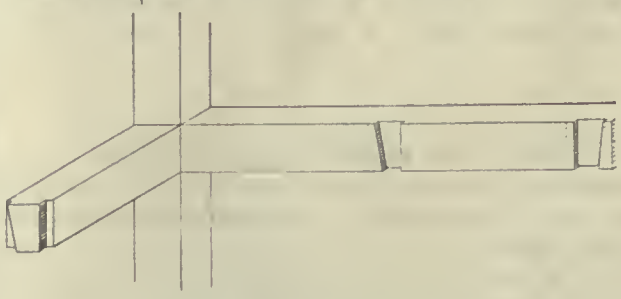
E. A. GRUSHUS.

Fort Bidwell, California, March 6.

[In replying to such inquiries as the above, where so little information is given and nothing is known of the existing conditions, it is necessary to assume average conditions, and upon such conditions the following conclusions are based. To give arbitrary figures of cost of work undone is not an easy matter. In problems such as this there must be a wide range of possibility. Often in isolated places work is accomplished with a small force of men, which although satisfactory, is not done by the least expensive method. One man, under such circumstances, is often found acting in the capacity of blacksmith, carpenter, hoist-man, time-keeper, and not infrequently he is also the superintendent. There is also a difference in the cost whether the work is carried on night and day, or on day shift only. The single item of keeping the horse will illustrate this. If 2 men can do a job in 2 days, in which a horse is a factor in the cost, it will be cheaper to put 4 men on and finish it in 1 day, thus cutting down the expense of feeding the horse. In this instance we will assume that the work is so arranged that but 5 men are employed: the blacksmith, who is also all-around man on top, and 4 miners down below. When required, one of the miners may be employed on the surface as assistant, to the hoist-man (blacksmith, etc.). He will be required most when the timbers are sent down, at which time he places them in the bucket and lashes them to the hoisting rope. The man below takes them out, and upon the arrival of the bucket at the top a second load is sent down. When all the timbers for a set have gone down the extra top-man also goes below and the two men then proceed to put the timbers in place. In this case the top-man does the blacksmithing, frames timbers, dumps the bucket as it arrives at the surface, disposes of the waste or ore on the dump, or elsewhere, keeps time, cares for and drives the horse when hoisting, and attends to all of the wants of the men down in the shaft on his shift. The problem of handling water has not been mentioned, but if there is much water a hoist-man should be on duty at night also. Timbers 6 by 6 in. are light for shaft work, and if only moderate pressure should develop they would be found unsatisfactory. It is suggested that it would perhaps be wiser to use at least 6 by 8-in. timbers, placing them with the broad side up. Having considered everything that seems pertinent to this work, the conclusion is reached that such a shaft as mentioned would cost an average of about $22.75 per foot of depth, or, perhaps, 38c. per cubic foot. It is unusual to estimate the cost of shaft sinking by the cubic foot, but if the cost for one foot in depth be determined, it is an easy matter to arrive at the cost of a cubic foot. The shaft suggested would be about 6 by 10 ft. outside of the timbers, and if the rock 'breaks big,' it would in all probability be of still larger dimensions than those mentioned. The cost of hoisting only, which contemplates the wages of the top-man while employed in this work, and the cost of keeping the horse all the time, would be $1.30 per foot in depth of the shaft, or $0.0216 per cubic foot. The whole cost per foot in depth, is estimated as follows:

Drilling	$11.20
Powder, fuse, caps, etc.	1.36
Blacksmith, coal, breakage of tools, etc.	1.30
Mucking	2.80
Hoisting (top-man)	0.40
Horse	0.90
Timber (500 ft. B. M. per set)	2.00
Placing set (including building and removing platforms under last set)	2.50
Framing timbers 1 set (top-man)	0.30
Cost per foot of depth	$22.76

The accompanying sketch shows a good and inexpensive method of framing timbers for such a



Timber Framing for Small Shaft.

shaft, either vertical or inclined. It shows one corner, with the posts in place both above and below the corner of the plates. Also the way the end pieces and the centre piece should be framed, as well as the beveled mortice cut to receive these pieces. In using shaft timbers of small dimensions this is a better way to frame them than to attempt the overlapping corner. Many miners cut a shallow 'dap' at each corner of the shaft, both on the upper and the side of the timbers, to receive the posts. This keeps the latter from slipping inward. These daps are not shown in the sketch. They are generally cut ½ in. deep.—W. H. S.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The best size to use on portland cement molding would ordinarily be glue and alum size put on thin and warm, made in proportion of ½ pound of glue and same weight of alum dissolved in separate pails, then poured together.

A cement for pipe joints is made as follows: Ten pounds fine yellow ochre, 4 pounds ground litharge, 4 pounds whiting, and ½ pound of hemp, cut up fine. Mix together thoroughly with linseed oil to about the consistence of putty.

Overloaded machines and structures, decayed gangways, worn-out floors and stair-treads, unannealed chains and hooks, frayed and stranded ropes and tackle, and a host of minor industrial equipment, are items which should pass under systematic and intelligent review from time to time as possible sources of accident.

Electric hot-plates are very convenient for laboratory use, and while electric energy is theoretically expensive for heating, it is economical in use as the heat is concentrated at the point desired, and this makes the plate so much easier and more convenient to work around that less heat is wasted. Hot-plates can be home-made, using Krupp resistance wire, but it is less trouble to buy them ready made.

In order to make labels adhere to metal or stone, lay a piece of mending fabric used by tailors under the label, and heat the whole. If the heating can not be accomplished by means of a spirit lamp, the label should be ironed down under a protective cloth or paper in the same manner as woolen goods are pressed. This method is also very useful for attaching paper labels to minerals. Another way to make labels adhere to metals or minerals is to put a coating of glue or varnish over them after they are stuck to the surface.

If good, clean, yellow brass sand castings are desired, the brass should not contain over 30 per cent of zinc. This will assure an alloy of good color and one which will run free and clean. Tin or lead may be added without affecting the property of casting clean. A mixture of 7 pounds of copper, 3 pounds of spelter, 4 ounces of tin, and 3 ounces of lead makes a good casting alloy and one which will cut free and is strong. If a stronger alloy be desired, more tin may be added, but 4 ounces is usually sufficient. If the alloy be too hard, reduce the proportion of tin.

Glass roofs, the skeletons of which are constructed of iron, are extremely difficult to keep water-tight, as the iron expands and contracts with atmospheric changes. To meet this evil, it is necessary to use an elastic putty, which follows the variations of the iron. A good formula is: Two parts rosin and one part tallow, melted together and stirred thoroughly with a little minium. This putty is applied hot upon strips of linen or cotton cloth, on top and below, and these are pasted while the putty is still warm, with one edge on the iron ribs, and the other, about one-fourth inch broad, over the glass.

Metals for casting purposes should not be overheated. If any of the softer metals shows blue colors after cooling, it is an indication that the metal is too hot. The metal should be heated enough so that it can be poured, and the finished casting have a bright, clean appearance. The mold may be very warm, then the metal need not be so hot for bright, clean castings. Some of the metals will not stand reheating many times, as this will cause them to run sluggish. Britannia metal should not be skimmed or stirred too much, otherwise there will be too great a loss in the dross.

The mending of defective places in grindstones is best done with a mass consisting of earth-wax (so-called stone-pitch), 5 parts, by weight; tar, 1 part; and powdered sandstone or cement, 3 parts, which is heated to the boiling point and well stirred together. Before pouring in the mass the places to be mended must be heated by applying red-hot pieces of iron to them or using a plumber's torch. The substance is poured into the hollow of the stone and the pouring must be continued while it cools and shrinks until it is even with or slightly above the surface. It must then be carefully smoothed off.

Castings of any metal can be done in a plaster mold, provided the mold has dried, at a moderate heat, for several days. Smoke the mold well with a brand of rosin to insure a full cast. Where there are only one or two ornaments or figures to cast, it may be done in a mold made out of dental plaster. After the mold is made and set enough so that it can be taken apart, it should be put in a warm place and left to dry for a day or two. When ready to use, the inside should be well smoked over a gaslight; the mold should be well warmed, and the metal must not be too hot. Very good castings may be obtained in this way; the only objection being the length of time needed for a thorough drying of the mold.

A quick and convenient way of doing lettering neatly is to use the gummed black letters sold by stationers. These can be had in several different sizes. In a large office where many tracings are made that need to carry approximately the same title, those parts of it which do not vary may be carefully lettered on tracing cloth and then a negative made from this by printing on an ordinary film in a printing frame. Several negatives can be made in this way, and in making a blue-print one of these is placed in the frame together with the tracing. The title will then appear in blue letters on a white ground, and the necessary addition can be made with an indelible pencil. Another good way is to print off a number of labels on thin paper; one of these can then be pasted on the tracing. Small printing outfits can be obtained at no great expense.

SILVER KING COALITION M. CO. JUDGMENT

The decision handed down by Judge J. A. Marshall in the Federal Court at Salt Lake on April 10, in the trespass suit of the Silver King Cons. *v.* the Silver King Coalition Mines Co. involved many points of interest. The plaintiff company was awarded a judgment of $734,242.80. The contention of the plaintiffs was that the defendants had worked a number of claims owned jointly and had failed to account for ore extracted. The trespass was proved; the opinion of the justice was that the defendant had intended to obscure the question where accuracy was readily obtainable and should therefore be made to bear the burden of the uncertainty due to its fault.

"I find as the extent of the excavation 573,937 cu. ft., in which there is waste and caved material amounting to 435,350 cu. ft.; that there has been removed from the excavation since this suit was commenced 31,551 cu. ft. of the waste. This waste and caved material now found in the excavation, of course, fills a larger volume than when it was solid and unbroken. I find that this expansion amounted to 100%; so that originally this material amounted in volume to 233,450 cu. ft. This leaves 340,487 cu. ft. of the excavation which was removed as ore which is to be divided into first and second-class ore. At this point the evidence is absolutely uncertain. To attempt to make an accurate division based on this evidence would be nothing but a guess, and the only certainty about it would be that the guess would be wrong. Nothing is left but to conclude that one-half of the volume was first-class and one-half second-class ore. Of the first-class 9 cu. ft is found to constitute a ton, while 12 cu. ft. of the second class is equivalent to the same weight. The result is that 18,916 tons of first-class and 14,187 tons of second-class ore was extracted.

"There is a great want of certainty with respect to the value of this ore. The price of the metals and the metallic contents of the ores change from day to day. There is no reliable evidence as to when the ores from this stope were marketed. Under these circumstances I think the defendant must be held for the highest monthly average price received by it for ores during the period of the taking. This price as to first-class ore was $60.07. The total received for first-class ore then amounted to $1,136,284.12; the cost of mining, tramming, and sampling the ore amounted to $6.33 per ton, or a total cost of $119,738.28, leaving a net value of $1,016,545.84. As to the second-class ore, the highest net value during the same period was $3.53 per ton, and the total net value is therefore $50,080.11. The defendant is also entitled to a further credit of $34,097 for the cost of development work confined entirely to the Vesuvius claim, and which was necessary to the extraction of this ore. The result is that the net total amounts to $1,032,528.95, one-half of which, or $516,264.47, is due to the plaintiff. To this should be added simple interest at 8% per annum from January 1, 1906."

The following costs and values per ton for the Silver King Coalition Mines Co. are of much interest in view of the above judgment:

2500 tons shipping or first-class ore.

Smelter returns		$44.60
Mining cost	$5.56	
Sampling and tramming	0.63	
		6.19
Net values per ton		$38.41

10,000 tons milling and second-class ore (concentration, 3.5 into 1).

Gross or metal value		$16.02
Mining cost	$5.56	
Milling	1.51	
Milling losses	4.16	
Sampling and tramming (percentage for freight and smelting per ton of concentrate)	3.98	
		15.36
Net value per ton		$0.66

The above clearly shows that the profits of the mine have been due to the returns upon its shipping ore, and to but little extent upon its mill returns. The considerable milling loss (25.4%) was due to the fact that the second-class ore was largely oxidized. The cost of sampling is given at 22.1c., of tramming at 40.8c. per ton. The cost of mining the ore in the Parsons stope and delivering the sand at the surface was between $5.65 and $5.75 per ton. This does not include interest on the investment nor other fixed charges. The cost of milling, not including interest on the investment nor general expense, was, for 1905, $1.549 per ton of crude ore, for 1906, $1.931, and for 1907, $1.888, and for the entire three-year period $1.766 per ton. It will thus be seen that the figure given for the cost of treatment of ore from the Parsons stope for the 10,000 tons of ore first specified is less than the average for the three years, probably because of the ease of treatment of Parson's stope ore. The cost of running drifts and cross-cuts is given at $12 to $14 per foot, a single compartment raise $13 to $15, three-compartment raises $22 to $25, and winzes $15 to $18. In these cases the ore was trammed half a mile underground, then hoisted 1300 ft. Miners worked 8-hour shifts and had the delays due to removal of powder smoke and of getting to and from the working face.

GOLDFIELD CONSOLIDATED

In his report for March, J. F. Thorn, general superintendent, gives the following figures:

During the month of March 1911 the total production of the company was 25,714, containing $1,119,951.75, or an average extraction of $43.55 per ton, of which the whole was milled with an average extraction of $41.38 per ton, or 95.45%. The total net profit to the company was $846,283.13, or $32.91 per ton.

Development work: 3960 ft. of development work was performed during the month of March.

Operating costs: the total cost of mining, development, transportation, milling, office and general expenses was $8.55 per ton, distributed as follows:

Mining:

Development	$1.22	
Stoping	2.21	
		$3.43
Transportation		0.10
Milling		2.44
Marketing		1.22
General expense		0.56
Bullion tax		0.63
Construction		0.17
Total cost of operation		$8.55

In the Combination mine an orebody has been opened in the foot-wall of an old stope on the second level that has produced 565 tons of ore worth about $169,500, or about $300 per ton. It is impossible to estimate the extent of this orebody, but the indications are that it will extend to the surface, at least 50 ft. above the present back. The stope is now 20 ft. long and 15 ft. wide, and is being extended in length. In the Mohawk mine the 354-sill has been considerably extended, and has produced 1320 tons of ore worth $66,000, or $50 per ton. And nearly 100 ft. farther into the foot-wall another orebody was cut that seems to be from 8 to 10 ft. wide. One hundred feet of driving has been done on this shoot, and has produced 430 tons of ore worth $38 per ton. This is probably a branch from the big orebody cut in the 354-sill. In the Clermont mine the downward extension of the 306 orebody on the 600-ft. level (near Laguna) was cut by an intermediate 40 ft. under the 600-ft. level. Not enough work has been done to estimate either the tonnage or value of this orebody. In the 750 north drift 6 ft. of $15 ore has been cut. The face of the drift is still in ore. The indications, however, are that it is not a very long shoot. Nothing of any importance has been found in the Red Top, Grizzly Bear, or Laguna. The mines as a whole are looking well.

Special Correspondence

BLACK HILLS, SOUTH DAKOTA

Success of the Employees Aid Fund.—Claims Paid. — Evans Con. — New State Mine Inspector. — Hidden Fortune Sale. — General Notes From the Black Hills.

After operation for three-quarters of a year, the Homestake Employees Aid Fund has made a splendid record. Under the plan of operation employees contribute $1 per month each, and the company gives $1000. Benefits, $800 for death, insanity, or total disability, down to $1 per day for sickness or inability to work caused by injury, are paid. The disbursements for the month of March, made on April 18, are a sample of those of past months. The cash account shows receipts: From employees, $2942; Homestake Mining Co., $1000; cash on hand March 1, $6216.80; interest March 1 to 26, $8.49. Disbursements: death benefits, $2400; injury, $922; sick, $659. Cash in treasury March 31, $6186.29. Thus during the month there were three death claims paid. The benefits included fourteen for $31 each, going to men who had not been able to work a single day during the month, and run from that amount down to 50c. In all 158 checks were made out, representing as many different claims against the fund. The fund is a complete success and is well liked by all employees.

The Evans Consolidated Mines Co. is the name of a newly incorporated organization that has secured a large tract on Spruce gulch, including the Lexington Hill and some adjoining properties. A large amount of money was spent by former owners, but work was suspended, owing to internal difficulties, at a time when a comparatively small amount of money might have developed ore. The new company finds itself possessed of a 20-stamp cyanide mill and the usual surface buildings, and will start work in a vigorous manner when the weather settles. The Gilt Edge-Maid company has been fortunate enough to secure the services of N. Treweek as superintendent. Mr. Treweek was State Mine Inspector for South Dakota for six years, until April 1. This company will proceed at once with the erection of a concentrating plant, and in the meanwhile Mr. Treweek is directing the work of opening the mine to supply a large tonnage. The Black Hills smelter works, at Galena, under the management of Paul Danckwardt, is getting things moving in good shape, after suffering delay by the failure of the railroad to finish the siding to the plant. Material is now being delivered and work is being pushed on the excavations.

R. L. Daugherty, of Lead, took office as State Mine Inspector on April 1, succeeding N. Treweek. Mr. Daugherty is a man of large experience in the Black Hills, and for some time prior to his appointment was a shift-boss in the Homestake mine. Previously he had been employed at the Holy Terror and other mines in the Hills. The term of office is two years. Sheriff's sale of the Hidden Fortune property, to satisfy receiver's costs, taxes, etc., amounting to about $36,000 will be held May 6, if further postponement is not made by the court. Several persons have examined the property, and stockholders have labored hard to straighten out the financial difficulties, but it seems at the present moment that the mine will go to outsiders. It is known that the Homestake would be a willing purchaser at the price named in the foreclosure proceedings, and the Golden Reward, it is stated, is willing to take the mill, if it can be gotten cheap. It is quite possible that the two companies will combine at the time of the sale, buy the property, and divide it between them on the foregoing basis.

The North Homestake company, at Maitland, resumed work on April 17 with a crew of three shifts in the shaft. The three-compartment shaft is to be sunk from the 220-ft., or present level, to the 500-ft. point. The Minnesota company, at Maitland, has started a crew of miners driving a tunnel near the southwest corner of the ground to make available for mining a vein of free-milling ore. As soon as the tunnel is completed and the tramway tracks extended the mill will be started. Milling operations will be resumed at the Reliance, at Portland, on May 1. The mill, since suspension of work, has been remodeled by removing the Chilean mills and substituting stamps. The work is under the superintendence of M. E. Hiltner.

Eastern interests have secured an option on the Gladiator group, on Deadwood gulch, the property of Burt Rogers, of Deadwood, and will shortly begin development. This property is situated in what is locallly known as the phonolite belt. Development has so far shown at various points on this belt bodies of ore of varying value, and some smelter shipments have been made. It is, however, practically virgin territory, and indications warrant careful development. The Forest City group, near Hill City, has been bonded by Colorado people, and this highly promising free gold prospect will be thoroughly developed. The ground is owned by John Forsyth and associates. The Forest City Mining Co.—no relation to the foregoing—is steadily operating a small stamp-mill near Oreville on high-grade free-milling ore, and is preparing to deepen the main shaft.

The Golden Slipper, in the Hill City district, which is being worked for the benefit of creditors, is producing some handsome ore. The vein was recently picked up after a fault, and now shows three feet of quartz that will mill close to $50 per ton. Mr. Kamman, superintendent for the Pa-Ha-Sa company, which took over the properties of the old Harney Peak Tin Co., has been directed to dispose of placer ground owned by the company. The company owns a large number of placer locations that have been farmed for years, and these will be sold.

BUTTE, MONTANA

New General Manager.—Colorado Mine.—Development at the Ophir. —Rich Ore in the North Butte.—Encouraging Result at Tuolumne. —Silver Lake Mining Company.

Harry Gallwey, for several years superintendent of the Parrot Silver & Copper Mining Co., has been appointed general manager of the Butte, Anaconda & Pacific railway. The position of superintendent of the Parrot goes out of existence with the appointment of Mr. Gallwey to the railway's service.

W. H. Wiley is engaged in making an examination of the Colorado mine of the Davis-Daly company in the interests of Eastern stockholders and until his report is made to those for whom he is making his investigation nothing will be decided on as to the future. The recent find on the 1700-ft. level has been opened a distance of 250 ft. by drifts, but the orebody has now practically pinched out. So far as opened it runs from 18 in. to 16 ft. in width. Men are now engaged in driving for the orebody on the 1500-ft. level.

The Ophir mine of the Butte Central Copper Co. will not reach the depth of 1000 ft. before the end of July, which is a few weeks later than at first calculated, for the reason that a pumping station has to be cut at a depth of 750 ft. At the present time the water is being pumped from the 500-ft. level to the surface, and as soon as a depth of 1000 ft. is reached an electric pump will be installed. Those in charge are very confident of the future, and it is just possible after the shaft has gone down to a depth of 1000 ft. another contract will be made for the sinking of 500 additional feet. In regard to the proposed concentrator, it is learned that no further steps will be taken until ore is blocked out sufficient to pay for it three times over.

The North Butte people still continue to be very reticent as to the recent rich bodies of ore opened up, but it may be stated on good authority that none of the reports sent out have been exaggerated. Among those who are quite familiar with the situation, it is positively asserted that the vein found in the shaft at 2750 ft. is a north branch of the Edith May vein, east of the fault. Both the width and richness are remarkable.

Cross-cutting on the 1600-ft. level of the Tuolumne has met with success beyond the expectations of the management. A few weeks ago cross-cutting north and south was commenced and the veins were reached within forty-eight

hours of the same time. The north vein was found first, and a rich body of ore opened which will run at least 12% copper. The exact width and extent are not yet known. The south vein joined the Edith May vein, and this was found even more valuable than the north vein. The shaft is now reaching the 1800, where a station is to be cut, after which it will be continued to a depth of 2000 ft., where another station will be cut.

The Silver Lake Mining Co. has filed articles of incorporation for carrying on a general mining business and for the construction and operation of a railway from the Georgetown district to the spur of the Butte, Anaconda & Pacific railway so as to bring the ore from the district to the smelter at Anaconda. The company is incorporated for $1,500,000, divided into 150,000 shares at a par value of $10 each. The company owns the George and Bonanza mines, and negotiations are pending for others in the locality. The George is a particularly rich mine and has a large amount of ore blocked out ready for shipment.

SOUTHEASTERN ARIZONA

Twin Peaks District.—Character of the Veins.—Exploration Work.—Geological Report.—Plant at Deep Shaft.—Organization of Company.—Frisco Milling Plant.

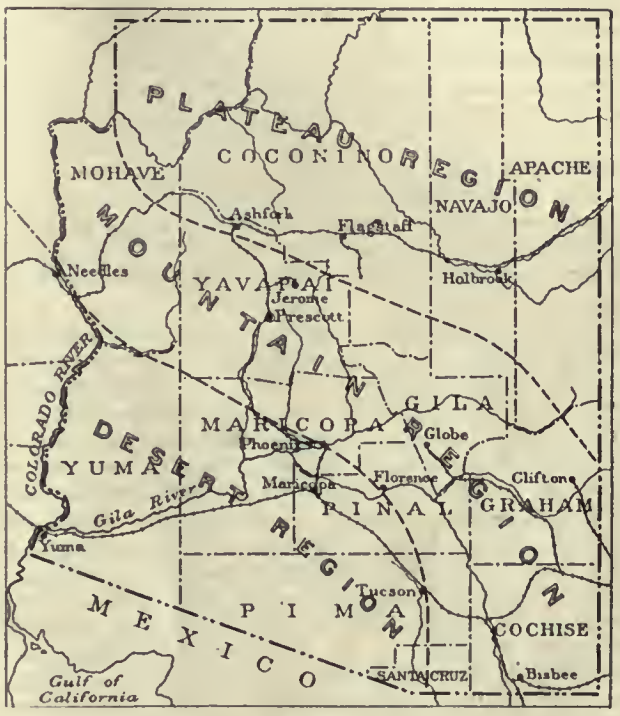
The Twin Peaks mining district lies on the New Mexico-Arizona line, 22 miles from the small town of Duncan, Arizona. The principal property is owned by the Twin Peaks Mining & Milling Co., having the following officers: Daniel Fraser, president and manager; John Evans, Jr., vice-president; A. N. Newhouse, secretary-treasurer; Alexander Fraser is superintendent at the mines, Joseph Fraser is fiscal agent, and James Fraser is superintendent of new work, consisting largely of prospecting throughout the tributary region.

The Twin Peaks ores contain gold and silver, principally the former. The country is andesite and rhyolite, resting upon granite. Numerous extensive porphyritic dikes traverse the country NE.-SW., which is the trend of the Twin Peaks vein. The vein here averages 8 ft. in width and looks like a fissure; though at depth it will probably prove to be a contact between andesite and the large porphyry dike. There are 32 claims in the property, with 15,000 ft. on the vein, which crops continuously for more than a mile. It has been worked for the past six years, and is now opened to 200 ft. in depth, with a great many shallow openings at different places. The first work done was on a high-grade shoot, about mid-length of the holdings, where a shaft was sunk 120 ft., all in fine ore. Water coming in, another shaft was sunk 160 ft. a few hundred feet from the first; and when water came in there, work was started on what was determined should be the main working shaft, now down 200 ft. At this depth water is now coming in, but all preparations have been made to take care of it, and here it is purposed to go to 400 ft., driving at each 100 level. In this shaft, at the 100, there are drifts east and west. The west drift, in 70 ft., is in a good body of high-grade sulphide; the east drift, 90 ft., is in oxide carrying more than $25 in free gold. The ore in the east drift is the same shoot showing on the surface for several hundred feet and which there carries an average of about $30. In neither drift is there water. The sulphide is a black material, much resembling the 'black metal' of the silver miners, but the greater value is in gold. On the 200-ft. level a station was being cut when I left the camp. The shaft was, however, in about 2 ft. of very fine ore, sulphide, and as the vein dips out of the work it is probable that the ore here fills the vein, which will be determined in the station work. There is a very large porphyry 'blowout' a few hundred feet west of the shaft, and they anticipate finding a good orebody when the drift in the vein shall have reached this point.

Geologically the district has been described as "both intrusive and effusive, including rhyolite, andesite, monzonite, basalt, granite, phonolite." There is a very little of the latter; this is not considered significant. The region is of course volcanic, and the metamorphism of the rhyolite has made great quantities of *mal pais*.

The gangue of the ore is silica and feldspar. During my stay at the properties I went over them carefully, and it was wonderful 'how it would pan.' At many places on the vein the material was broken off without attention, and in no instance did I fail to get a color, oftentimes a great many. The many open-cuts show rich ground. Near the extreme eastern end of the properties there is a 70-ft. tunnel, in ore all the way, the average being above $18 in gold.

The company has a well-equipped plant at the deep shaft, power being obtained from a gasoline engine. There are numerous comfortable houses for employees. There is a good road to Duncan. Some time ago the company bought a $50,000 milling plant for $3500, the former owners having found the plant entirely inadequate for the character of the ore they had to treat, and doubtless some portions of this will be installed at the Twin Peaks. The cyanide process will prove available for treatment. The company is financially solid, and the intention is to get depth as quickly as possible. The mine was discovered six years ago by James Fraser, and he, his brothers, and Mr. Newhouse carried the enterprise for four years, when a company was organized and some stock was sold. In the exploration, however, the original owners pooled their interests, and they take one share of stock for each share sold, this giving the investor



Arizona.

an equal share with them. Stock now has been withdrawn from the market. This company is the only concern working steadily for the past few years in the entire district, though there are many others owning properties.

Placer mining is being revived in the Clifton-Morenci district. Two new plants are being erected, one by the 'Frisco Placer Mining Co., and one by F. J. Paine, A. Hodgert, and W. M. Whipple. The plant of the 'Frisco company is an interesting one. The gravel will run into a large hopper and out over a grizzly; the large boulders from this travel down an inclined chute for 75 ft., to remove all adhering sand and cement. At the end of the chute the sand drops into a sand-bin; the smaller material from the grizzly passes into a bin and thence to a 1½-in. mesh trommel. The oversize from this goes to the waste dump and the fine goes into a sand-bin below, thence into $^{1}/_{16}$-in. mesh trommel; from the trommel the oversize passes through regular sluice-boxes to waste, while the fine passes into a sand-bin, thence to riffles, and finally through a Pearce amalgamator. It is believed this will save all the gold. The working is dry until the material reaches the two sluice-boxes beyond the last trommel. The plant is about 30 ft. above the Frisco river, from which any amount of water may at all times be secured.

NEW YORK

Reaction in Porcupine Shares.—Little Interest in West Dome.—Progress at Dome.—Utah Consolidated Meeting.—Broughton Sustained.—Proposed Restrictions on Stock Issues in Massachusetts.—Death of T. L. Chadbourne.—Lake Superior Merger.—Review of the Copper Situation.

It is an established principle in physics that action and reaction are equal. A large number of the members of the New York market are now ready to declare that the reaction is greater than any initial movement that can be imparted to the trading. When Porcupine started to lift, and the outside public began to make inquiry there was a remarkable demonstration. A wave of relief was apparent, a long breath was drawn, action was about to begin, and, indeed, did begin, only to subside before any results could be achieved. The market has settled back into a distinctly waiting attitude. The boomers of the camp are talking as big as ever, but the praises fall for the most part on deaf ears.

The slump in Porcupine was emphasized by the lack of interest taken in the flotation of F. Augustus Heinze's much advertised West Dome property. The public paid little heed to the quotations or the trading when the shares were introduced on the New York market this week. The activities at the camp are not, however, in any way lessened. The Dome Extension is to build a 40-stamp mill. The Preston East Dome is installing a plant, consisting of boiler, 6-drill compressor, pumps, and hoist. The North Dome is setting up two drills. Work is at a standstill on the Dome, but on the Hollinger development work is said to reveal extraordinarily good ore. Plans are being prepared for an addition to the plant in the way of three tube-mills to work in connection with the 30 stamps which are expected to be dropping by July, at which time it is expected that the cyanide plant and the tube-mills will also be ready to start.

The annual meeting of the Utah Consolidated held in Jersey City this week was marked by a somewhat acrimonious discussion between Urban H. Broughton and George L. Walker of Boston, who is the author of Walker's Weekly Copper Letter. Mr. Broughton's statement was in the nature of a defense of his administration and gave in detail the circumstances which led up to the examinations made independently by John W. Finch and C. C. Burger and the ensuing issuance of the circular announcing a heavy decrease in the estimated ore reserves of the company. The more important matters, with regard to the future of the property discussed at the meeting, were the impending retirement of Mr. Broughton as president and the results of the development work carried on during the past few months; some 14,000 ft. of work having been done with satisfactory results. In addition to the copper ores developed, lead ore has been found, and a considerable tonnage proved; it is estimated the ore will show a net profit of $6 per ton. Mr. Broughton was very decided in his expressions concerning the contract between the Utah Consolidated and the International Smelting & Refining Co., believing the contract to be worth a great deal to the mining company. The result of the meeting was overwhelmingly in favor of Mr. Broughton.

Stocks seeking a market on the Boston Exchange or on the Boston Curb are hereafter to run the gauntlet of legislative requirement if a bill now before the Assembly of the State of Massachusetts is passed. It provides that the president and directors must file a sworn statement giving name, location, amount of stock, and the name, address, and stock holdings of each shareholder, and a true description of the property. Within thirty days of each annual meeting a statement of condition, assets, and liabilities must be filed; at the request of one-fourth of the stockholders an examination must be made by independent engineers, while officers are made personally responsible for any impairment through mismanagement. Any broker dealing in shares not entitled to be listed is liable to a fine of $1000 or imprisonment for not more than three years, or both, and any promoter who advertises shares for sale without complying with the listing requirements, or who makes false statements in any certificate or report, shall be liable to a like penalty or penalties. All of which is certainly drastic enough to keep unscrupulous promoters at a safe distance from Boston if it becomes law.

The Calumet & Hecla merger lost one of its most important adversaries through the sudden death of Thomas L. Chadbourne, of Houghton, Michigan. Mr. Chadbourne died of heart failure at his winter home in West Palm Beach, Florida. He was counsel for the Calumet & Hecla in Michigan for many years, but resigned because of his opposition to the present merger plans, especially with regard to the Ahmeek. The Ahmeek property was an especial pet of Mr. Chadbourne, and because he thought unfair the basis on which it is to be absorbed, he fathered and pushed through the Michigan legislature a bill providing for appraisal of properties to be consolidated and for the purchase of the shares of any and all dissenting shareholders who may refuse to come into any projected consolidation. The Boston Stock Exchange sentiment has been against the big Lake merger for the reason that it will take so many active issues away from the traders. Floor members are taking some consolation from the fact that Isle Royale, which was expected to become a component part of the big company, is to remain an independent concern, though it will be conducted under Calumet & Hecla management. Isle Royale is considered, like Ahmeek, one of the greatest speculative possibilities among the Lake mines.

Copper has broken below 12c. and the position of the various important producers is causing some close figuring. Curtailment is tacitly acknowledged to have failed. New production, while it will not be a predominant factor during the current year, must be reckoned with during 1912. Ray Consolidated, Miami, Chino, Braden Copper in Chile, and the Kennicott in Alaska, will all be in line by the end of the year. In the meantime the hoped-for revival in general business has not come and the metal market can not be said to have improved. There are many large producers that are making barely a safe margin over present dividend requirements. Of the more important factors in copper production there seems to be but five that can earn present dividends on current production with 12c. copper, namely: Calumet & Hecla, Utah Copper, Nevada Consolidated, Old Dominion, and Granby. There are smaller deep-level properties, such as Tuolumne, Butte-Ballaklava, Shattuck Arizona, and some others that have just now some rich orebodies out of which they can make a large profit for the time being. Such properties can not, of course, be justly compared with the porphyry mines. The Ray Consolidated plant is fast getting into action. The first section of the mill is treating 850 tons per day, getting extraction of about 70%. The concentrate, which runs about 30% copper, is now being sent to the smelter at El Paso. The second section of the mill is to be started this week. The Ray Consolidated ores are running about 2.35% copper.

The annual report of the Miami Copper Co. shows ore reserves, as of January 1, 1911, of 18,000,000 tons assaying 2.58% in copper. Of the whole mineral ground 58 acres has been explored by underground work or by drills. Of the territory explored 15 acres show so low a copper content that it will not be worked farther. The annual meeting of the Miami was held this week and Theodore L. Herrmann was chosen as director to fill the place of Andrew Freedman, resigned. Mr. Herrmann is also a director of the Utah Consolidated. The first shipments of the concentrate from the Miami to the smelter at the Greene-Cananea have just been made. The first tests of the Miami mill have just been completed with the gratifying result that the capacity of the plant has been found to be much greater than was expected. The first unit can handle 700 tons per day, which is nearly twice as much ore as it was estimated to treat. The mill is equipped with Deister tables and is to be one of the most complete plants of the kind in the country.

The development at the Hidden Creek property, under option to the Granby, is said to be encouraging, some 4,000,000 tons of ore having been developed, averaging 2½% copper. This ore is to be sent to the smelter at Granby.

Operations at the Granby are liable to be somewhat curtailed in the near future owing to labor troubles of the Crows Nest Pass Coal Co. The British Columbia Copper Co., like the Granby, is extending its holdings, having taken an option on the McKinley property, sixty miles distant from the Greenwood smelter and twenty miles off the line of the Canadian Pacific. The figure named in the contract is $100,000, and the railroad has agreed to connect with the mine by a spur if the option is taken up. The activity in the stock of the Arizona Copper Co., which is traded in Edinburgh, has attracted some attention. The market rumor is to the effect that the new management, installed since the death of John Gill a few months since, is negotiating for a sale of the control to the Guggenheims.

WASHINGTON

Airing of Alaska Land Scandal.—Investigation Called For.—The Potash Controversy.—Closing the Mints.—Investigation of Pancoast Disaster.—Bureau of Mines Appropriation.—Workman's Compensation Act.—Bills Introduced.

The Alaska mineral-land scandal has once again been hung out on the Senatorial wash-line for an airing, all through the adroitness of Robert La Follette, the insurgent Senator from Wisconsin. The Senator the other day introduced an innocent-appearing little resolution, calling upon the new Secretary of the Interior to transmit to the Senate a list of all claims, locations, filings, or entries made upon lands withdrawn from the Chugach National Forest in Alaska and "restored to the public domain" by the Executive order of October 28, 1910; giving the date of each claim and the names of the persons who made the same, and also what, if any, assignments of these claims have been made, and to whom. Those who claim to know, say that the facts will disclose favoritism to the Morgan-Guggenheim interests in Alaska. It is understood that the administration will show that there is no reason to believe that the Guggenheim interests predominate in the management of the Controller Bay Railroad & Navigation Company.

Asbury F. Lever, of South Carolina, has introduced a resolution in the case asking the President for information as to what connection the resignation of David J. Hill as Ambassador to Germany has with the potash controversy. The South is taking a keen interest in this difficulty, as the increased price for potash demanded by the German syndicate in the face of contracts with Americans is seriously affecting the fertilizer manufacturers, all of whom use potash.

Washington newspapers are authority for the statement that the Government may close or abolish some of its mints. They say that Franklin McVeagh, Secretary of the Treasury, is ready to instruct the assay offices and mints to begin issuing gold certificates against gold bullion and foreign gold coin. As soon as this begins, the coining of gold will practically stop. Nothing but small silver coins and pennies will be struck off hereafter, unless there is an unusual demand for gold coins, and it is estimated that the mints at San Francisco and Philadelphia, running on short time, will fill all the Treasury's needs. A saving of several hundred thousand dollars per year will be effected by the change.

An investigation into the cause of the death of Joseph E. Evans, the miner employed in rescue work by the Bureau of Mines, who lost his life while trying to save the entombed miners at the Pancoast colliery, at Throop, Pa., is now under way. Newspaper dispatches to the effect that Evans' helmet was defective and that he tore it off in the mine are not believed here in Washington. Director Joseph A. Holmes gives the theory that in the excitement of the rescue work, Evans worked so hard he used up the oxygen more rapidly than it could be supplied. In other words, the caustic-potash cylinder could not absorb the poisonous matter from Evans' breath rapidly enough to prevent him from breathing it again before it was purified. That the widow of the hero, Evans, has not been forgotten is seen in the action here and at Pittsburg. At the present time two separate funds are being collected for the widow—one a subscription from the Bureau of Mines employees, and the other from mine operators and mining engineers, who are greatly interested in rescue work. The latter fund has been started by John Hays Hammond, who has subscribed $250.

In the rush incident to the closing of the last session of Congress, a few typographical errors crept into the Sundry Civil law, one of which sought to give the Bureau of Mines $135,000 for fuel investigations instead of $100,000 which was really allowed by Congress. John J. Fitzgerald, New York, chairman of the new appropriation committee, has introduced a resolution in the House which will restore the old figure.

Joseph Howell, representative from Logan, Utah, has introduced an amendment to the workman's compensation act which, if passed, will extend the benefits of this law to employees of the Bureau of Mines, engaged in hazardous work. The act provides that workmen and employees on the Isthmian Canal and for the Reclamation Service who are injured shall be entitled to receive their pay for one year. Martin D. Foster, of Illinois, the chairman of the new committee on Mines and Mining in the House, has introduced a bill to apply a portion of the proceeds of the sale of public lands to the endowment of schools or departments of mines and mining. Bills have also been introduced to repeal the duty on coal and coal slack or culm, bitumen and asphaltum, and iron ore. Atterson Rucker, Fort Logan, Colorado, has introduced a bill providing for the cession by the Government to the States of all unoccupied public domain.

JOHANNESBURG, TRANSVAAL

Shaft Sinking on the Western Rand Estates.—Width of Reef.— Cast-Iron Shaft Lining. — Centrifugal Pumps. — Bailing Skip.—Pilot Drills.—Globe & Phoenix Mine.

The Western Rand Estates Co. Ltd., owning a large block of gold claims on the extreme southwestern part of Witwatersrand, is carrying out most interesting sinking operations in the aqueous dolomites which overlie the reef on that company's property. A series of bore-holes was put down on the farm Gemsbokfontein—the property of the company—a few years ago, and these disclosed the presence of two principal gold-bearing reefs. The first of these auriferous conglomerates encountered was termed the Western Rand Leader and was struck in three bore-holes at depths of 1972, 1677, and 2302 ft. respectively. The assay value and reef widths disclosed in the cores were as follows:

Hole.	Inches.	Dwt. per ton.
No. 4	10.5	158.0
No. 8	15.5	18.83
No. 9	8.0	6.6

The lower reef, known as the No. 2 West Reef, was encountered in eight bore-holes at depths varying from 2004 to 3229 ft., the width of reef disclosed varying from 5 to 29 in., and the value from 2.5 to 22.74 dwt. per ton.

The company commenced sinking a circular shaft on Gemsbokfontein in September 1909, but owing to difficulties encountered in sinking through soft decomposed chert and dolomitic breccia, the depth at the end of last June was less than 80 ft. Work is now proceeding at a better rate, but the shaft will have to penetrate between 1200 and 1300 ft. of dolomite, which has never before been attempted in South Africa. The shaft is 17 ft. 9 in. in the clear, and will be lined throughout with lead-jointed cast-iron lining, varying in thickness from $1^3/_{16}$ in. for the first 100 ft. to about $2^1/_4$ in. at the lowest depth of the water-bearing strata. The whole shaft will be completely water-tight, the lining being strengthened by concrete filling behind. The lining is made in ten segments to the circle, the width of each ring varying from 2 ft. 6 in. to 5 ft. Bearer-rings, which will be let in at intervals on the solid rock, project 2 ft. beyond the circle. The matter of handling water has been met by the installation of two Sulzer pumps, capable of raising over 2,000,000 gal. per 24 hours. These pumps are a novelty on the Witwatersrand. They are cen-

trifugal and are operated by a 300-hp. motor; a balling skip of new design has also been delivered on the property. It consists of a tubular contrivance, capable of holding 600 gal. of water, and provided with a tight-fitting piston which is capable of being operated by the hauling wire. On reaching the bottom the piston automatically sinks to the bottom on the slack and on being raised sucks up water through a clack-valve and fills the skip. The shaft is at present being sunk by hand, but it is intended to install machines at a later date. Pilot drills are kept at work in the bottom of the shaft to minimize the danger of a sudden rush of water from the bottom.

The Globe & Phoenix is the most notable mine in Rhodesia, partly on account of its rich ore and partly because of the attraction its shares have had for speculators. The workings are deep, the main shaft being down to 2481 ft. on the dip. During the last year or so, most of the development has been on the sixteenth and seventeenth levels above and below an intrusive dike. Operations have recently been hindered by necessary overhauling of the plant and retimbering the main shaft. The presence of antimony has caused trouble to the metallurgist. When 3-oz. ore yields only 2¼ oz., it means the loss of what is practically another gold mine, and the dump provides the enterprising metallurgist with an interesting problem. During the past year the repairs to the shaft have made it impossible to raise sufficient ore to keep the extraction plant going, so the directors decided to mine ore richer than the average so as to make the total profit the same as if the mill had been at work the whole time on average ore. Thus 88,397 oz. was recovered from 41,257 tons, realizing £376,372 and yielding a profit of £236,569. The dividend was 115%. In spite of hindrances to development the ore reserve has been fully maintained throughout the year and stood on December 31 at 178,221 tons averaging 33.9 dwt. The orebody is notable for the occurrence of rich shoots running to 5 and 6 oz. gold per ton. Many improvements in metallurgical treatment have recently been introduced by H. T. Brett and much of the antimonial sulphide is now removed by concentration and roasted. During the last month or so the extraction has by this means been raised from 75 to 86%. It is possible that before long a further more drastic alteration of the plant will be undertaken and all-sliming introduced.

KALGOORLIE, WESTERN AUSTRALIA

Diamond-Drilling at the Great Boulder. — Encouraging Results. — Associated Northern Option. — Drop in Bullfinch Shares. — Deviation of Drill-Holes.—Low Water-Supply. — Use of Motor Vehicles.—Super-Phosphate Production.

Some encouraging results have been obtained by diamond-drilling at 2800 ft. in the Great Boulder. A series of holes was put in toward the Ivanhoe and Horseshoe boundaries with the following results: A horizontal bore westerly from the main shaft cut ore at 194 ft., it being 19 in. wide and worth $170 per ton. At 210 ft. 14 in. of ore, worth $23, was cut. From the same point, another hole, at 220 ft., cut 3 ft. of ore worth $57, and 6 ft., assaying $22, close to the Golden Horseshoe boundary. One hole from the Boulder was continued into the Ivanhoe, and encountered a lode 12 ft. west of the east boundary, and 57 ft. north of the south boundary, it being 3 ft. wide and worth $21.50. Further drilling at 2800 ft. in the Boulder in a southwest direction, at 95½ ft. from the shaft, a vein 1½ ft. wide was cut, worth $36; and at 144 ft. cut 2 ft. of ore worth $86, 13 ft. from the boundary. The Ivanhoe reports that in cross-cutting west at 2270 ft. they passed through 2 ft. of ore worth $4.58 per ton, 139 ft. west of the main shaft. This is supposed to be the middle lode, which has not been worked below the 1669-ft. level. The Perseverance at 2050 ft. reports 6 ft. of profitable ore. The shaft is down 2200 ft., and the cross-cut 140 ft. The sixteenth level of the Chaffers in the Main Reef shaft shows a 5-ft. vein worth $3.50. The Great Boulder announces its reserves at 803,151 tons containing $7,934,696. No estimate has been made of the No. 1 lode below No. 1 level; of No. 2 lode below 1650 ft.; of No. 3 below 1767 ft.; and of No. 4 below the 10th level. Rather good news comes from the St. George mine of the Boulder No. 1, at Mt. Magnet, in that a new lode 12 ft., worth $30 per ton, has been cut in the cross-cut east from the north end of the 100-ft. level. The Associated Northern has taken an option on the Gimlet South and South Extended leases for six months. The price asked is $170,000. A boiler, winch, condenser, etc., are already on their way to the mines, and work will soon be started. The Bullfinch Proprietary has erected a Cornish boiler, and a hoist for sinking the new main shaft, and other development. There has been a great drop in the shares of this mine lately, partly due to reports from outsiders warning people not to rush into speculation on the Yilgarn field. The trial of the late Chaffinch manager and others will come on shortly. The Associated Northern is still drilling from the 550-ft. level; but no ore is cut, and it would seem that there is nothing below the once famous pipe of ore, which comes into the property at 300 ft. from the Brownhill lease, and leaves again at 550 ft. into the Oroyo North block. The mine keeps one ball-mill at work, the other two being on custom ore, which comes in from all parts. Referring to diamond-drilling on this field, it is to be hoped that cross-cutting in the Boulder will disclose the good ore found in the bore. There is a lot of chance about a bore-hole, as most mining men know well. Serious deviations take place, and it seems that the drill always tries to work at right angles to the strike of the rocks. Richard Hamilton, of the Boulder, gave several instances of this in his address at the annual meeting of the Australian Institute of Mining Engineers in 1909. A London paper recently published the story that the deviation of a drill was due to magnetism, tending to drive it away from the pole toward which it was boring. Experienced men here do not accept the argument.

As we have had no rains for many months, water in some of the outside centres is very low, and others have had to close down mines until it rains. Large dams with a clay or cement bottom have been constructed at most places, but evaporation is high. As in Nevada and other mining States of the United States, the motor-car has been very valuable in Western Australia in prospecting and carrying passengers to new fields. The motor buggy is fairly satisfactory, as it is high, and can clear stumps and rough ground easily.

During 1910 the Collie coalfield produced 261,587 tons, this being 47,207 tons ahead of the previous term. This coal is used on the railways, mixed with Newcastle coal, and on steamers calling en route to the east; 518 men are employed. The Northampton field produced 125 tons of lead ore, valued at $6000. About 400 tons of black tin was won on the Greenbushes and Marble Bar fields; while 2300 tons of copper was produced from the mines at Phillips river and West Pilliarra. It may be of interest to note that a ship laden with 1500 tons of copper ore from the latter field, was caught in a cyclone recently and overturned, only one man out of 23 being saved. Renewed interest is being centred in the Ora Banda field, north from Kalgoorlie. The wheat production of this State is increasing rapidly, and good results are obtained by using super-phosphates. There are two large plants near Perth for its manufacture, operated by the Mt. Lyell Co., and by Cuming, Smith & Co. The former can hardly meet the demand for its product. Phosphate rock comes from Christmas island, in the Indian ocean; while sulphide for acid manufacture comes from Huelva, in Spain. It is hoped before long to use deposits of these minerals which occur in Western Australia. The phosphate rock is broken in jaw-breakers, and ground in a ball-mill. The sulphide is crushed to about ½-in. size, and roasted in Herreshoff furnaces. Both nitric and sulphuric acids are made at the works. The resulting product is bagged and transported to the farming districts. Taking advantage of a trip to the coast, I inspected this plant, also the lime treatment of the water supply at Mundaring weir. The latter is working satisfactorily, the inside of the main conduit is getting coated with lime, this preventing further corrosion, while the corrosive element is being precipitated out.

General Mining News

ALASKA

JUNEAU DISTRICT

It is expected that $600,000 will be spent during the summer on the Alaska-Juneau in the construction of a mill and in development work. F. W. Bradley, the president of the company, will visit the mine soon. The De Groff Mining Co. has purchased the adjoining Mills mine and will proceed to enlarge the mill on its own property at Chichagof, near Sitka. A San Francisco company is opening the Bear's Nest mine on Douglas island. The California-Nevada Copper Co. is working three shifts and will eventually employ 200 men.

KETCHIKAN DISTRICT

Large bodies of magnetite have been discovered near Sulzer on the Kasaan peninsula, and at other places in this district, but are as yet undeveloped. Recently the suggestion has been made that they might be profitably worked if electric smelting were used, as in Shasta county, California.

THE TANANA

(Special Correspondence.)—An important deal was put through recently when L. M. Drury and associates took over the entire property belonging to Hoel Bros., Johnson & Witmer. This comprises four claims on the divide between Wildcat and Vault creeks. On two claims a vein 30 ft. wide has been traced for 1000 ft. A 2-ton sample from one of the prospect-holes on this vein recently milled $9 per ton. The vein on the other two claims is smaller and higher grade, running from 8 in. to 2 ft. wide, a one-ton sample from which milled $45 in the Fairbanks mill. There are two 80-ft. shafts on the latter, and a 60-ft. drift at the bottom of one. The new owners are planning development on a larger scale this summer.

Owing to a blockade of the railroad for most of the month, due to heavy snows, only three runs of ore were put through the Chena customs mill. A run of 8 tons from J. C. Kinney at Ester netted $256, or $32 per ton. L. J. McCarty, at the head of Fairbanks creek, also sent in 39 tons which gave a bar worth $4740, or well over $100 per ton. The largest returns were from 52 tons shipped from the Rhoads Hall mine on Bedrock creek. The bar weighed 415 oz., the gold being worth $16.42 per ounce, or a total of $6814. This is probably the last shipment to leave the claim, as W. C. Hall is now in San Francisco getting a mill to be erected this summer. The next run at the Chena mill will be 70 tons or over from the Golden-Sherrard lease at the head of Cleary. A small run taken by milling every tenth sack shows that the entire lot will average $105 per ton.

Herchberger & Zimmerman are opening up a very promising vein between Twin creek and Skoogy gulch. There are 20 tons of rock on the dump at present. The vein varies from 1 to 5 ft. thick and assays well. A mill-run will be made soon. Two very good samples of galena have come in recently. One from the Excelsior, owned by Cook brothers, on Fairbanks creek, assayed 313 oz. silver and $3 in gold. Another sample from Freeman and Scharf at the head of Fox gulch showed 260 oz. silver and $6 in gold. After being closed down for several months the Tolovana mine will start stoping. George Hunter, the manager, has just returned from the outside. The mine has paid all its expenses during development. A mill run on 5800 lb. completed recently netted $250.

Steady development work is going on at the Peterson lease on the Friedrich vein. Adits are being driven at a depth of 120 ft., and very good ore has been found on both sides. This property will probably erect a mill this summer. Having almost raised the necessary $20,000, the Quartz Development Co. will soon commence operations. At present, the board of directors is looking over properties that have offered favorable propositions. With the choice of the property to work on, no difficulty will be experienced in raising the rest of the money needed. Hoel Bros., Johnson & Witmer, who recently sold out their Vault creek holdings, are getting a plant and will soon start to open up some good prospects found by them at the head of Treasure creek.

The Fairbanks Core & Drill Mining Co. will soon put an issue of stock on the market. The purpose of the company is to bring in drills and prospect quartz properties for an interest. A large set of tools will also be brought into the country to prospect placer ground where the holes will not be over 200 ft. deep. E. H. Mack is secretary and general manager for the company.

The famous No. 17 Goldstream will be worked from four shafts by Petersen & Kellum. The first clean-up has already been made, giving returns of over $5000. To further investigate the dredging ground, tied up by Lemons and Powell last year, Dupree Lance, a London mining man, has just arrived with two of the directors of the company, H. J. Robson and William Turton. The properties lie on Fairbanks and Pedro creeks.

Dredge on Bonanza Creek.

Fairbanks, March 21.

ARIZONA

COCHISE COUNTY

A big discovery of lead and silver ore has been made in the Arizona-Cleveland in the Gunnison range of the Dragoon district. The richest ore runs 600 oz. silver; the company expects to ship a 30-ton carload this month. A large air-compressor and a 50-hp. hoist have been ordered. The East Side Gold M. Co., ten miles east of Bisbee, is preparing to erect an air-compressor and a gasoline hoist. Fourteen men are at work on the property of the McKinley Mining & Development Co. The most important thing at present is to get the roads in shape, after which $10,000 will be spent in improvements.

GILA COUNTY

The recent test of the Miami mill showed the surprising result that it can be operated at nearly double its rated capacity. Unit No. 4 is now ready for operation; this is equipped with Burch rolls instead of Chilean mills, and units 5 and 6 will be equipped with either Burch rolls or Chilean mills. The capacity for six units will be 4000 tons. Three tons of concentrate was shipped to Cananea, April 11 and 12.

YAVAPAI COUNTY

The vein opened in the lower tunnel of the Starbuck mine averages 4 ft. in width and carries high-grade silver ore. The find is considered the most important one ever made on the property. Placer gold amounting to $180 was brought to Prescott last week from the claims on Oak creek, which belongs to George Brook and Harry Schlosse.

YUMA COUNTY

Gold has been discovered about 25 miles northeast of Yuma and 16 miles east of Brawley, and many prospectors are on their way to the scene of the find. In the North

Star claim of the Copper Reef Con. Mines Co., the crosscut from the 300-ft. station of the inclined shaft is in 25 ft., while the California adit is in 760 ft. and has cut the California vein, which is 14 ft. wide, with 18 in. of good ore.

CALIFORNIA

CALAVERAS COUNTY

The mill-men at Angels Camp quit work on Monday on account of a 50c. reduction in wages per day. The 5-stamp mill at the Duryea mine in Chile gulch was sold last week and will be moved to about a mile below the Foote & Thompson on the Mokelumne river.

ELDORADO COUNTY

The *Mountain Democrat* reports that L. J. Strait, whose work was stopped by the Débris Commission until a dam should be built to hold the débris, has devised an entirely new plan of operation which obviates the construction of an expensive dam. H. C. Cline is re-opening the Davidson mine at Shingle Springs; a shaft is being sunk to the 300-ft. level. A 10-stamp mill will be erected to treat the ore, which averages $14.50 per ton. A party of students from the University of California is exploring a cave in the limestone, near Cool, and has made some interesting finds. Good ore has been struck in the Barney mine, near Omo. W. A. Bell is beginning to re-open the Dalmatia mine, near Kelsey, which was closed down some years ago. A test run has been made at the Georgia Slide mine, at Georgetown. A large new mill is planned.

KERN COUNTY

The Yellow Aster mill is handling 500 tons per day of ore that will average $2.75 per ton, and is making good profits. The Inyo Coso company is finding high-grade ore in its new adit, which is in about 400 ft. The aerial tramway, made by A. Leschen & Sons for the West Gold M. & M. Co., in Wilson canyon, is being delivered. A 50-ton redwood tank for the Arondo mine, in the Argus range, has been delivered. The U. S. Geological Survey has completed its field work on the Ballarat quadrangle.

SAN BERNARDINO COUNTY

The Needles smelter is treating only 100 tons per day at present, but by the middle of next month is expected to be in full operation at its rated capacity of 350 tons per day. The core-drill, to be used in prospecting the Desert Chief mine, is daily expected in Barstow. A tube-mill will be erected at the Bagdad-Chase mine, near Barstow, by G. E. Roth, to treat the tailing.

SHASTA COUNTY

The 25-ton furnace at Heroult has been in regular operation for some time with but few brief delays. The work on the construction of the three new furnaces, which will require 6000 hp. more, is being hurried and it is expected to have them ready by the first of July. The National mine, near the head of Churn creek, which was abandoned a couple of years ago, has been explored by G. M. Sleezer, who has found good ore, and has re-located the property. He has shipped 60 tons of ore that averaged $45 per ton. The new stamp-mill on the Uncle Sam has started. The Old Diggings district is busy supplying siliceous ore to the smelters.

SIERRA COUNTY

Men are at work repairing the damage to the North Fork ditch, and later the Middle Fork ditch will be repaired also. This was carried away by a snowslide. It is planned to blast deep enough into the bank so that any subsequent slide will go over the ditch without injuring it. Shaft-sinking is in progress on the vein from the lower adit on the Plumbago mine. Work has started again on the Standard mine, which closed down early in January. The contract has been let for the construction of the 10-stamp mill for the Tightner mine. It will have 1200-lb. stamps and the pulp will pass to two concentrating tables and then to buddles and vanners after it has gone over the plates. The slime will be treated in a cyanide plant. The mill will cost about $20,000. The mill is 700 ft. from the dump, so a tramway will be built to convey the material to the mill. It is expected that $50,000 profit will be made in treating the dump.

TUOLUMNE COUNTY

The new 10-stamp mill at the Duffield, near Arastraville, will be started about May 1. A new pump is to be erected. ——The electrical equipment for the Gold Ship mine, near Groveland, has been ordered and will be supplied by the D. D. Demarest Co. The order includes an electric hoist, two 40-hp. transformers, a 50-hp. motor, and a pump. An electric transportation system and a lighting system will probably be installed in the near future. It is understood a large amount of development work will be done during the present year.——The 5-stamp mill being installed at the Gianelli mine, above Arastraville, will soon have its 15-hp. gas engine running. The vein, 4 in. to 3 ft. in width, is one of the richest yet uncovered in the district, assaying from $10 to $500 per ton.——Electric power is to be used at the Humbug gravel mine, at the base of Table mountain, near Jamestown, at which active operations will be resumed as soon as the branch transmission line, now well under way, is completed. The mine is worked through a long tunnel which taps the channel beneath the mountain, and in the early days yielded much gold.——Several shallow shafts have been sunk at the Mill Villa to determine the value and extent of the gravel deposits, and the results indicate that the enterprise will prove profitable.

The management of the Tarantula mine will concentrate its efforts on the development of the property. A large force is employed in the mine. It is reported that the new 20-stamp mill will soon be in operation. The company's holdings comprise several claims on the Mother Lode near Shawmut.——Title to the valuable holdings of the Tuolumne River Power Co., consisting of 65 miles of ditch, water-rights, power-sites, etc., has passed to the Yosemite Power Co., whose principal stockholders are said to be Maine capitalists. It is said that the purchasing company will expend several million dollars in the construction of an electric-power site.

Tuolumne, April 22.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—From a shipment of eight tons of ore made from the lease on the Lamartine being operated by Charles Carlson, the sum of $800 was realized. ——A body of ore from 2 to 7 ft. wide has been uncovered in the stope being carried in the west drift of the Bellman vein. Tests show value of 2.50 to 3.25 oz. gold per ton. George S. Wilkie is manager.——The track at the Newhouse adit is to be extended from the dump down Clear creek as far as the Wilkie mill. The plant will be run upon ore from the Saratoga mine.

Idaho Springs, April 14.

GILPIN COUNTY

(Special Correspondence.)—A big body of medium-grade ore has been uncovered on the 100-ft. level of the Baxter mine on Quartz hill. There is also showing an 8-in. streak of smelting ore that is worth from 10 to 15 oz. gold per ton. G. R. Gibson is manager. Anderle & Co., leasing on the Egyptian mine, are shipping 50 tons of ore each month that brings $21 per ton in gold and silver.——The Coeur d'Alene M. Co. has completed a road from the mine to the county road, and shipments will be started at once. The water in the Grand Army workings has lowered to the 1200-ft. point. It has been decided to allot the ground to lessees.——Shipments from the Champion mine are averaging $18 per ton; the ore being taken from the 800-ft. level.

Central City, April 14.

SUMMIT COUNTY

(Special Correspondence.)—The Shoe Basin mine, which is owned by Peoria, Illinois, people, who also own the Peruvian mine, advanced its tunnel 216 ft. during March, and on April 1 was in a distance of 936 ft. The tunnel was started October 25, 1910; it is expected to cut the Peruvian vein at 1025 ft., but 1250 ft. remains to be driven on the

vein before connection is made with the old Peruvian shaft, which shows continuous ore to the bottom of the shaft.

It is understod that the Little Jumbo mine, operated by Mr. Rosengarten, who is one of the oldest operators now in the district, is going to build a 100-ton mill this year. There is an ore-shoot developed at good depth and a large amount of ore blocked out. The ore is lead-zinc carrying silver and gold, and the orebody is continuous for 700 ft. in the lower tunnel, and averages over 4 ft. wide. It is heavily mineralized and it is only a matter of separation to make a lead and commercial zinc product. The ore is very similar to that of the Wellington mine at Breckenridge, but carries more silver.

The Colorado Toledo mill started operation April 1, and is operating one 8-hour shift daily, with the usual trouble in separating the iron from the zinc. The mine has large orebodies and two 8-hour shifts are being worked, blocking out ore while experimenting with roasting, so as to make a better separation. The construction of the mill has proved satisfactory, and it can handle ore more economically than any other mill in the district. The Wagner process, as well as the Motter method of separation, is under investigation.

Montezuma, April 13.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—The Stewart mine, controlled by F. A. Heinze, is making a good showing. Five hundred tons of ore is sent to the mill every day and first-class ore at the rate of 600 tons per month goes to the East Helena smelter. The first-class ore runs 40% lead and 40 oz. of silver per ton. The second-class is concentrated 6½ into 1, and the concentrate runs 50% lead and 30 oz. in silver. The Stewart has cleared off all indebtedness, except about $50,000, and that will be paid off in about six weeks.

One hundred thousand dollars is being expended to make the Hunter mine, near Mullan, one of the best equipped plants in the Coeur d'Alene district. Among the improvements contemplated are the enlarging of the mine and the installation of an electric hoist and electric trains for hauling ore from the shaft to the bins on the tunnel level. The capacity of the mill will be increased from 400 to 800 tons daily. The latter work is to be completed early in June. One hundred and fifty men are at work, the principal operations being on the 400-ft. level.

Separations as clean as could be desired and with a small loss are being made in the mill at the Success mine in the Coeur d'Alene. Sufficient ore is broken down in the stopes to run the mill several months, and there is enough ore blocked out to assure a steady output for several years. Some of the stopes that were worked twenty years ago are being re-opened and are ready to yield a large tonnage. Having been worked for the lead alone, most of the clean zinc, or mixed lead and zinc, was left on the walls.

Development work on the Federal company's mine at Mace, Idaho, has opened a large orebody on the 1800-ft. level. The ore was encountered at No. 12 chute and has been driven on to No. 22 chute, a distance of 400 ft. It is believed to continue to the end line of the Mammoth claim. The new ore is superior to anything that has been opened in the mine and prolongs the life of the property indefinitely. A new orebody, showing 13 inches of steel galena, was discovered recently in the 1400-ft. level. The west drift in this level was extended to the end line of the claim, and it was within a few feet of the line where the new ore was found. The company is negotiating for the purchase of the Cleveland claim, into which it is believed the orebody extends.

Favorable indications are seen in the Northern Light property in northern Idaho, where a find of importance was made in a cross-cut from the shaft at a distance of 65 ft. from the surface. The shaft began in ore which dipped at about the depth of 40 ft. Several stringers of ore were cut in sinking the shaft. The cross-cut picked up one of these at 10 ft. and shows that the vein had widened to fully 10 ft. and that it is full of ore, the richest galena showing throughout the quartz. The cross-cut will be continued to cut the other stringers, and as these were better in the upper workings than the one just discovered even more is expected of them. The shaft will be continued to a depth of 100 ft. before the next cross-cut is made.

Wardner, April 22.

MONTANA

FLATHEAD COUNTY

(Special Correspondence.)—Preparations are being made for an active season by placer miners in the Libby Creek district in western Montana. The Libby Creek Placer Mining Co. is arranging to erect a small sawmill to cut lumber for flumes and buildings about twenty miles south of Libby, where it holds a large area of ground. Operations have been started on the Rice placer claim in the Republic district, where there is abundant water this spring.

Spokane, April 20.

SILVERBOW COUNTY

(Special Correspondence.)—The St. Lawrence mine of the Anaconda group, after having been closed for several months during which the shaft was retimbered, has resumed operations.

According to all reports there is much activity in the Radersburg district, and there is a large amount of Eastern capital being put into both old and new properties. The Ohio, the Ohio Keating, and the Black Friday are shipping regularly, while development work is going on in the Bluebird, Mammoth, Combination, Keating, and the Rena. Locations are being made north of the Keating to the schoolhouse near the town, while all the ground two miles south of the Black Friday into South Radersburg district has been taken. W. L. Credon, the mining engineer, has just returned from the district where he has been making an examination of ground for Duluth capitalists.

A suit has just been filed in the district court against the East Butte Copper Mining Co. for $30,000 for personal injuries. John D. Wiser alleges in the complaint filed that while employed by the company he was working in a coal-bin when one of the cables attached to a large elevator used in lifting the coal, broke and struck him across the back, breaking several ribs, injuring his back and causing internal injuries.

Butte, April 24.

NEVADA

CHURCHILL COUNTY

The new shaft at the Nevada Hills, at Fairview, is down 200 ft., but no cross-cutting will be done until 650 ft. is reached, when connection will be made with the Wingfield and Fairview Eagle veins and the old Nevada Hills workings. The machinery is being delivered and electric power should be available on May 15. The company is advancing $40,000 to the hydro-electric company to build the power-line and will 'take out' this sum in power. The mill will have a capacity of 125 tons per day and will cost about $250,000. An illustrated description of it appeared in the *Mining and Scientific Press* of April 8.

CLARK COUNTY

The Searchlight M. & M. Co. has started its 50-hp. triplex pump on the fourth level, and no difficulty has been experienced as yet in keeping the water down. The pump has a capacity of 500 gal. per minute and is motor-driven. The electric generator is 100 hp. and furnishes current for electric lighting the plant and company houses.

ESMERALDA COUNTY

The Goldfield Con. will pay a dividend of 50c. per share today, corresponding to its regular quarterly dividend of 30c. plus an extra dividend of 20c. This will amount to $1,779,574, making the total paid in dividends to date by this company $14,587,035, or a total of $4.10 per share. The quarterly statement will also be given out.

HUMBOLDT COUNTY

The Hutchinson gold strike, near Mill canyon, is confirmed by many mining men who have since visited the camp. Tom Kearns has taken an option on the property.

Rich ore has been found in several different places, and it is hoped that the camp will prove a big one.

Mike Timmons, who has a block of ground with the Kindergarten Mining Co. at Seven Troughs, is reported to have obtained $3600 worth of gold from 670 lb. of ore.

NYE COUNTY

The total shipment of the Tonopah district for last week amounted to 7786 tons, of a value of $194,650. Of this, the Tonopah M. Co. sent 3150 tons; Belmont, 2200; Tonopah Extension, 980; Montana-Tonopah, 1006; West End, 400; and Midway, 50. The Big Four Lease has made its second mill-run, of about 400 tons of ore, which will average about $80 per ton. The management is much encouraged by this excellent showing.

STOREY COUNTY

The Mexican produced one-half of the ore of the North-End last week, its output amounting to $11,000. North drift No. 2, from the east cross-cut on the 2300-ft. level, has been driven 7 ft., yielding 19 cars of ore averaging $68.27 per ton. The face is all in ore of the same grade. South drift No. 2 has been extended 10 ft., yielding 20 cars of ore averaging $58.53 per ton. The north drift from the east cross-cut No. 2 on the 2400-ft. level was driven 39 ft. and turned to the east, exposing a 7-ft. vein from which 15 cars averaged $17.91 per ton. In the raise at the end of the north drift 86 cars, averaging $74.88 per ton, were taken out. The roof is now 61 ft. above the 2500-ft. level. Ophir continues to stope a good tonnage from the Hardy vein on the 2100-ft. level. The Yellow Jacket mill was only operated part time during the week on account of a shortage of ore, but 476 tons of Crown Point ore and 160 tons of Belcher ore were crushed.

WHITE PINE COUNTY

The Steptoe concentrator is handling ore at the rate of 11,000 tons per day, all eight sections now being in operation. All the ore is coming from the Copper Flat cut of the Nevada Con. Two of the five reverberatory furnaces at the smelter are now being fired exclusively with oil. Within a short time the power-plant, roasters, and one of the engines will be fired with oil. All the shovels and engines working in the pits at Copper Flat will also be equipped with oil burners. One advantage of this will be the doing away with the cinders that get mixed with the ore and have a tendency to choke the screens in the mill. Good ore is being obtained from the Zack shaft of the Ely Con. The average over 20 ft. wide is said to be 6¾% copper. It is intended to continue sinking the shaft to the 600-ft. level.

OREGON

BAKER COUNTY

The Belcher mine, in the Greenhorn district, was sold last week by U. S. Commissioner G. L. Bender to satisfy a judgment, and was bid in by the representative of M. F. Douche for $25,814.60. There are more than 2000 ft. of underground workings in the mine. The North American mine at Beaumont was purchased at sheriff's sale by E. Callahan, of Baxter. It is reported that the Climax mine will be re-opened this summer. A small force of miners is engaged in driving a cross-cut to reach the vein on the Homestake near the Columbia mine. A. E. Dagany is in charge.

COOS COUNTY

The coalfields of Coos county are the most important in Oregon, and are one of the most valuable resources of that region, as coal mining is one of the leading industries of the county and has great possibilities of future growth. More recently central Oregon has been explored for oil and it has been found in commercial quantities near Vale, Malheur county. Coal occurs in Jackson, Josephine, and Polk counties, and these deposits also may develop in time into steady producers.

JOSEPHINE COUNTY

The Oriole mine, in the Galice district, has attracted much attention recently, several shipments of ore to the Tacoma smelter having netted good returns, and a recent shipment of 20½ tons netted $3724. The fourth tunnel is being driven into the orebody. This will be 950 ft. in length and will open a 'back' of some 600 ft. The ore-zone has been proved for a width of 40 ft. The vein is composed of quartz stringers and nodules interbedded in soft slaty material, the gold being in the quartz. The foot-wall is a metamorphic slate and the hanging wall a quartzite. The property consists of nine claims, with attached water rights.

PENNSYLVANIA

ALLEGHANY COUNTY

(Special Correspondence.)—On Friday evening, April 28, at the monthly meeting of the Pittsburg Railway Club, F. N. Speller, metallurgical engineer for the National Tube Co., will read a paper on locomotive boiler tubes. In the afternoon of the same day the National Tube Co. has invited the Pittsburg Railway Club to visit the Ellwood City plant where the members of the club will have an opportunity to observe the manufacture of cold-drawn steel tubes and hot-rolled seamless steel tubes.

The convention of the American Society of Mechanical Engineers will be held at Pittsburg, May 30 to June 2. Professional sessions will be held in the lecture hall of the Carnegie Institute, and there will be a number of inspection trips to various industrial plants in the vicinity; a boat excursion for the members and ladies up the Monongahela river, a reception and ball at the Hotel Schenley on Thursday evening, and, finally, on Friday evening a smoker and entertainment, given by the Engineers' Society of Western Pennsylvania, in their rooms in the Oliver building.

Pittsburg, April 20.

UTAH

JUAB COUNTY

Four carloads of ore have already been sent to the smelter from the recent strike on the 800-ft. level of the Mammoth. The ore has so far been opened for 35 ft. and is in entirely new ground. The production at the Iron Blossom has been slightly less this week. The Iron Blossom declared a dividend of 10c. per share, amounting to $100,000 last week. This is 4c. per share more than the preceding dividend. The total ore shipment from the district for the week was 184 cars, the Centennial-Eureka leading with 46 cars.

SALT LAKE COUNTY

(Special Correspondence.)—The Utah Society of Engineers held its annual dinner at the Commercial Club on April 20. M. D. Grosh was elected president, C. F. Moore and E. H. Beckstrand as vice-presidents, R. B. Ketchum as secretary, and A. S. Peters as treasurer, to serve for the ensuing year.

Salt Lake City, April 22.

SEVIER COUNTY

(Special Correspondence.)—The Sevier-Miller Coalition mine, situated sixteen miles from Sevier station, has been developed during the winter and has a big tonnage of gold ore exposed and much of it broken. The mill, which is equipped with stamps, amalgamating plates, and cyaniding machinery, is to be started about June 1. The ore assays about $10 per ton in gold, about half of which is expected to be recovered on the plates and the other half by cyanidation. In order to make the latter process more effective a Kelly filter-press is to be added to the present equipment. It is figured that the extraction will reach 90 to 95% of the assay value of the ore. The mill, which has a capacity of 200 tons per day, is equipped for operating by electric power, generated at the company's hydro-electric plant. B. F. Bauer, of the Salt Lake Hardware Co., and F. T. Tilton are largely interested in the property, the latter being in charge.

Sevier, April 20.

SUMMIT COUNTY

The strike of the men at the Silver King Coalition was settled last week by acceding to their demands, and three shifts are now at work. The judgment obtained by the Silver King Consolidated recently has been appealed.

TOOELE COUNTY

(Special Correspondence.)—The Bullion Coalition Co., having nearly 100 patented mining claims in Stockton district, including the Honerine and other groups, is operating with a force of 35 men and shipping 700 to 800 tons of lead-silver ore per month to the smelter; and there are 25 men working on leased ground of the company, from which about 300 tons of ore per month are being shipped. The ore samples 25 to 28% lead, and 20 to 30 oz. silver per ton, and a little gold. The principal vein has an east-west strike and is opened by adits. The old workings, which are in the hands of lessees, are entered through the original adit; the lower workings, where mining on company account is in progress, are entered through the 7000-ft. drainage and haulage adit, and connecting with the latter is a drift of 7000 ft. on the vein. This haulage adit, known as the Honerine tunnel, now has a flow of about 2000 gal. of water per minute. The Honerine concentrating mill, belonging to this company, and built several years ago, is not in operation.

Stockton, April 20.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The North Washington Power & Reduction Co.'s mill building is so near completion that some of the machinery is being erected. The last of it is expected to be delivered within a week. Estimates are being made of the ore tonnage likely to become available from the leading mines of the district, on which to base an enlargement of the mill. In the Quilp mine most of the work is at present confined to driving the Surprise drift from the 400-ft. level and shipping ore from the Callahan stope, above the adit-level. Ore assaying $35.86 per ton, of which $33.60 is in gold and $2.26 silver, is being shipped from the 500-ft. level from a stope 4½ to 5 ft. wide. The Republic Mines Corporation has sunk a winze 75 ft. below the 300-ft. level of the Lone Pine mine and is getting out $30 ore from a stope over 7 ft. wide. The Surprise continues to produce ore from the 210-ft. level and has a working face of $50 ore. A raise has been completed to the intermediate level, 40 ft. below the Jim Clark adit. The drift on the 600-ft. level from the Quilp 400 has reached a point under the cross-cut from the main incline, and a raise has been started in $30 ore, supposed to be identical with the orebody on the cross-cut, but there is a difference in elevation of 360 ft. between the two points. The company is awaiting smelter returns from 40 carloads of ore shipped last month. According to the last report of the superintendent, the Lone Pine assays have run up to $125 per ton in the past few days. The Knob Hill mine will probably make one of the best records in the camp, from the way it is opening up. In the No. 3 stope on the No. 2 level, a vein 6 ft. wide, 3 ft. of it on the hanging-wall side at the face, assays $96 gold and $8.50 silver, total $104.50 per ton. On the foot-wall it assays $328 gold and $15.50 silver, total $343.50 per ton. Back from the face 15 ft., the back of the stope assays $508 gold and $22 silver, total $530 per ton. The north drift is in 35 ft. on the pay-shoot. A general sample from the last 10 ft. driven assays $38.40 gold and $2.34 silver, total $40.74 per ton. During the past week the company has sent to the smelter 30 tons per day. The north drift continues running on a full face of ore. On the No. 4 level the north drift is being pushed ahead, and it will require 20 days longer to get under the orebody on the No. 2 level. The smelter returns from four cars of ore amount to $7506.65 gross value, as follows: two cars, about 30 tons each, assayed $61.25 per ton. The gross value was $3320.70 gold and $286.20 silver, total $3606.90. The other two carloads assayed $65.35 per ton, and the gross value was $3579.84 gold and $319.91 silver, total $3899.75.

Republic, April 14.

SPOKANE COUNTY

Announcement is made in Spokane that the Gold Nugget mines, including the Nugget, Coyote, and Bonanza claims in the Nelson district in British Columbia, have been acquired by J. T. Hillis and A. E. Baker of Vancouver, who will organize a new company, capitalized at $500,000, to build a cyanide plant and stamp-mill of 100 tons daily capacity. It is reported that Messrs. Hillis and Baker purchased the treasury stock, amounting to 142,000 shares, on which they had an option, and thus came into control.

The Factor Mining Co. has decided to expend $10,000 on the exploration of its property in the Orient district at Washington. The plans include a shaft of 250 ft. and a 300-ft. extension of the tunnel. The company expended $7555 in exploring 344 ft. of its property in 1910, and the results so far are highly satisfactory. G. A. Horley is president of the company, the secretary being M. E. Poole.

The San Poil Consolidated company, of which Robert A. Koontz of Spokane is president, will being installing machinery on its property at Republic, Washington, in a short time. The equipment consists of a 60-hp. engine and a compressor to drive two stope and three piston-drills. The claims to be developed are the Trade Dollar, the South San Poil, and the North San Poil. The Trade Dollar tunnel on the 300-ft. level will be driven 800 ft. J. L. Harper, general manager for the North Washington Power & Reduction Co., the Republic Mines Corporation, and the Imperator-Quilp Mining Co., announced in Spokane that the first unit of 250 tons of the mill at Republic, Washington, will be in operation by June 1. The plant will be enlarged to treat 1000 tons daily. Mr. Harper says that work is progressing on all the properties controlled by his companies.

There is much agitation over the proposal that the Dominion of Canada should buy Alaska from the United States. The mining districts which are along the international boundary meet a great deal of inconvenience from what amounts practically to being subject to two governments, and individuals who chafe under the restrictions of the Federal Forest Service hail the proposal with delight.

Spokane, April 20.

COLOMBIA, SOUTH AMERICA

The Concordia mine, which has recently been purchased by R. A. Linton for New York and London interests, has made a very large production, and with modern machinery will develop into one of the principal gold mines of Colombia.

MEXICO

SONORA

(Special Correspondence.)—M. H. Perry, who has been general manager for the Creston Colorada for the past four years and in a like position with the Chas. Butters company for 12 years, has gone to Salvador to take the managership of the Butters Salvador mines, held by the late H. P. Garthwaite.

La Colorada, April 14.

The San Lorenzo mine has been sold for $50,000 to the owners of adjacent property. It is reported that it is proposed to consolidate this and the Washington. In the San Lorenzo there is 80,000 tons of ore of 4% copper blocked out. This property was developed by Martin Hickinson, who will remain as superintendent.

A notice from the Department of Fomento under date of March 31 states that no more acquisitions of mining lands may be made by foreigners within a 60-mile zone along the international boundary. This will cause much trouble to foreigners who have denounced lands and then proceeded to form companies while waiting to obtain title.

ZACATECAS

Volney D. Williamson announced on April 12 that the Exploration Company of London has taken over the properties of the Santa Rosa de Mazapil Mining Co. and the Santa Rosa Development Co., situated in the State of Zacatecas, Mexico, eight miles from Concepcion del Oro. A corporation, known as the Santa Rosa Exploration Co., which is capitalized at $750,000, has been organized to acquire and develop the holdings.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. Wiley is at Butte.

D. C. Jackling is in New York.

A. F. Sherman is at San Francisco.

C. W. Purington has returned to London.

H. W. MacFarren is at Seattle, Washington.

John B. Keating has returned from Arizona.

E. B. Kirby was at Kingman, Arizona, last week.

Edmund Juessen was at Chaffee, Nevada, this week.

Charles Janin has returned from southern California.

Wilbur A. Hendryx left New York for London, April 19.

Otto Sussmann passed through Salt Lake last week on his way East.

O. H. Packer is examining placer mines in Butte county, California.

J. Malcolm Maclaren is expected in San Francisco from New Zealand.

Ernest H. Simonds has returned to San Francisco from Trinity county.

E. R. Haggin is now with the Candelaria Consolidated Mexican M. Co., San Dimas, Durango.

Owen Letcher is on his way to London from South Africa, traveling by way of the East Coast.

H. T. Durant has severed his connection with the firm of Hommel, Durant & Co., 6 Broad Street Place, London.

Lu C. Tyler has opened an office at 156 South West Temple street, Salt Lake, for assaying and chemical analyses.

Victor C. Heikes, statistician for the U. S. Geological Survey, stationed at Salt Lake, spent last week in Nevada.

Thomas L. Chadbourne, who died recently at Palm Beach, Florida, was for many years counsel for the Calumet & Hecla.

C. Colcock Jones returned to Los Angeles from the Santa Maria oilfields and left April 22 for mine examinations near Nogales, Arizona.

William Seward Mann is building a stamp-mill and cyanide plant for the Pilones Mining Co. at La Portilla, Durango, Mexico.

J. M. Callow has been appointed consulting mill engineer for the Inspiration Copper Co., with C. H. Repath as constructing engineer.

The San Francisco Section of the Mining and Metallurgical Society will meet following dinner at Techau's Tavern, Monday, May 1.

William R. Jewell has returned to Bakersfield from Arizona, where he has been engaged in making a geological examination of oil land.

E. R. Buckley addressed the Mining Club of the Missouri School of Mines on March 28, on 'Importance of Geology to Mining Engineers.'

Joseph H. Playter has returned from examination work in Sinaloa and Sonora, Mexico, to the management of the Nevada Crown Mining Co., Golconda, Nevada.

Lewis A. Parsons and John I. Kane have formed a partnership under the firm name of Parsons & Kane, and have opened offices at Coles building, El Paso, Texas.

B. F. Bush, who has just been made president of the Missouri Pacific railway, is an experienced and capable mining engineer who made an excellent record in handling coal mines in Washington, Illinois, and Missouri.

W. H. Landers has resigned as superintendent for the Standard Con. M. Co., Bodie, Mono county, California, and will be succeeded by J. R. Buchanan, the present assistant superintendent. Mr. Landers will devote most of his time to opening up the Reward mine near Independence, California, in which he is interested with A. J. McCone.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE

The question of contributory negligence in an action for the death of a miner, killed by the sudden starting of machinery about which he was making repairs, is one of fact to be determined by the jury.

Janoski *v.* Northwestern Improvement Co., 176 Federal 215. Feb. 1910.

INJURY TO MINER—ASSUMPTION OF RISK

A coal miner employed in the operation of a mine was directed by his superior to operate an electrical engine used to draw coal cars up an incline. He had had no experience in running the engine and was given no instruction. In operating the engine he was required to keep his foot upon a brake which vibrated with the action of the engine, and while thus engaged his foot slipped from the brake and he fell against unguarded gearing and was injured. The operator of the mine was chargeable with a breach of duty in directing the inexperienced miner to run the engine without proper instruction, and the fact that the danger of the unguarded gearing was apparent if a person fell into it, made the question of the assumption of the risk and of contributory negligence questions of fact for the jury to determine.

Montana Coal & Coke Co. *v.* Kovec, 176 Federal 211. Feb. 1910.

INJURY TO MINER—ASSUMPTION OF RISK

James Bateman, a miner, sued his employer, the Utah Consolidated Mining Co., for damages as the result of burns caused by an explosion in a converter which threw molten metal out of its mouth as he stood in front of it to skim the slag from the metal. He alleged that the presence of moisture in the parts of the converter subjected to contact with the molten metal rendered them liable to explode and to throw the metal out of the converter, and that the employer was negligent in the preparation and inspection of the converter in this, that there was moisture in the clay with which it was lined where it was liable to come in contact with the molten metal, and that such moisture did come in contact with the metal and caused the explosion which injured him. The plaintiff had for two years been a skimmer, one of whose duties was to skim or rake the slag from the molten metal into the converter, and the explosion, resulting in the injury, occurred in the clay lining of the converter which threw the molten metal out of the mouth of the converter and burned him. For three months before the accident he had used converters dried with the mixed fuel and had subjected them to the test of the molten metal; he knew that if moisture remained in the clay lining and the molten metal came in contact with it there might be an explosion. He had used this mixed fuel to dry the converters and knew that there had been explosions in converters dried by the use of this fuel and that such an explosion might throw molten metal out of the mouth of the converter, yet with this knowledge he remained in the employment and continued the work without complaint. On this evidence the United States Circuit Court for the district of Utah held on appeal that the plaintiff assumed the risk and danger from the use of the mixed fuel used in drying the converters and that a servant assumed all the ordinary risks and dangers of the employment upon which he entered and in which he continued without complaint, including those resulting from the negligence of his master which are known and appreciated by him and those which would have been known and appreciated by a person of ordinary prudence and care in his situation; and a servant will not be heard to say that he did not appreciate the danger where the defect from the negligence of the master was obvious and the danger from it would have been apparent to an ordinarily prudent person.

Utah Consolidated Mining Co. *v.* Bateman, 176 Federal 57. Feb. 1910.

Recent Publications

Biennial Report of the State Geologist. By J. H. Pratt. North Carolina Geol. and Econ. Surv. Pp. 152. Raleigh, 1911. Covering operations for 1909-1910.

High Terraces and Abandoned Valleys in Western Pennsylvania. By W. E. Shaw. From *Jour. Geol.*, Vol. XIX, No. 2, Pp. 139-156. Chicago, 1911. A brief study of the development of these puzzling physiographic features.

Preliminary Results of Tests with Explosives in the Field. By Clarence Hall. Pamphlet. Pp. 11. A paper read before the Mine Inspectors Institute of the United States at the Chicago meeting of 1910 and giving results of work done by the U. S. Bureau of Mines.

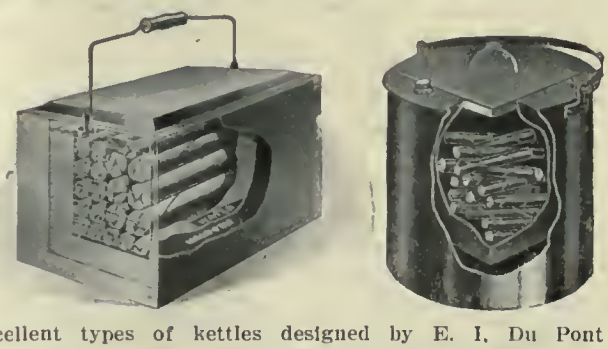
Geology of the Pegmatites and Associated Rocks of Maine. By E. S. Basten. U. S. Geol. Surv. Bull. 445. Pp. 152. Ill., index, map. Washington, 1911. A careful study of these interesting rocks with résumé of theories of genesis. The economic importance of the bulletin lies in the relations of pegmatites to ore genesis in general and to the occurrence of feldspar, quartz, mica, and gems locally.

The following advance chapters from the Mineral Resources of the United States, 1909, have recently been issued:

'Production of Iron Ore, Pig Iron, and Steel in 1909,' by Ernest F. Burchard; 1911; 30 pp. 'Production of Phosphate Rock in 1909,' by F. B. Van Horn; 1911; 7 pp. 'Production of Chromic Iron Ore in 1909,' by Ernest F. Burchard; 1911; 5 pp. 'Production of Bauxite and Aluminum in 1909,' by W. C. Phalen; 1911; 14 pp. 'Production of Manganese Ore in 1909,' by Ernest F. Burchard; 1911; 15 pp. 'Production of Barytes and Strontium in 1909,' by Ernest F. Burchard; 1911; 6 pp. 'Production of Mica in 1909,' by Douglas B. Sterrett; 1911; 14 pp. 'Lithium in 1909,' by Frank L. Hess; 1910; 7 pp. 'Production of Magnesite in 1909,' by Charles G. Yale; 1911; 5 pp.

THAWING DYNAMITE

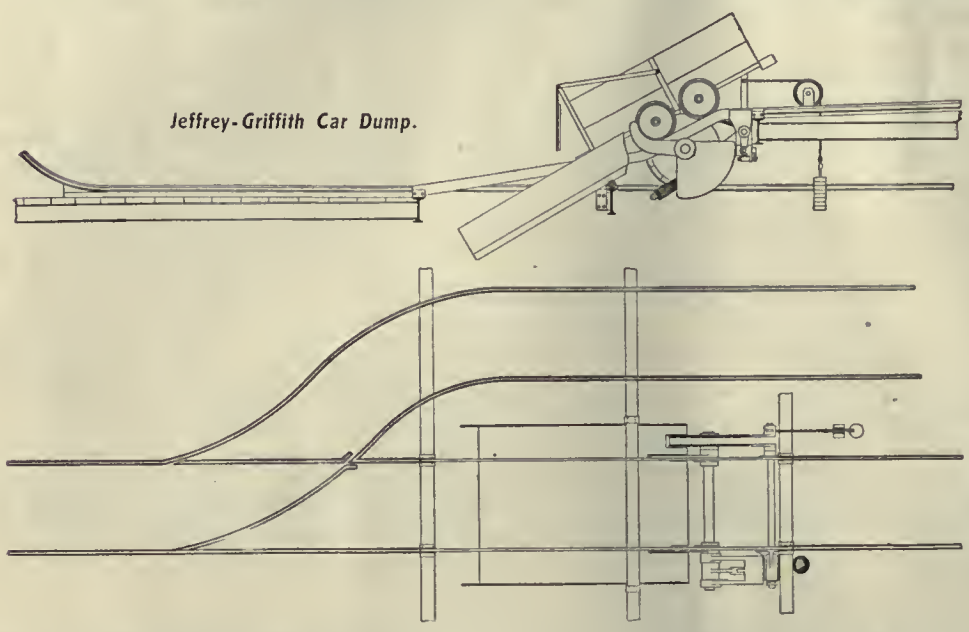
Thawing dynamite is an operation requiring much care. Nearly everyone recognizes the danger of the improper methods formerly employed, such as toasting before a fire, frying on a boiler, and roasting in an oven, but a number of users of explosives do not yet appreciate the loss incurred in improper methods of thawing which may be perfectly safe. For instance, it is fairly safe to plunge a lot of powder into tepid water, provided that the nitroglycerine which leaks out is taken care of so that it does not explode at some unexpected time, but the loss in efficiency of the dynamite in a work where any considerable quantity is used, would pay for an efficient thawing apparatus many times over. The illustrations show two



excellent types of kettles designed by E. I. Du Pont de Nemours Powder Company for thawing small quantities of dynamite. Anyone with a piece of paper and a pencil can readily figure out what loss of efficiency, say, 40% dynamite incurs when it is soaked with water so that it will only do the work of a 30% dynamite. In addition to this, the hazard of having a quantity of free nitroglycerine around is very great.

JEFFREY-GRIFFITH CAR DUMP

The Jeffrey-Griffith patented dump shown herewith, recently developed, is said by the makers as a cross-over dump to possess features which make the dumping or flow of the coal almost continuous in its movement over the dump. While it is guaranteed to have greater capacity than is possible to obtain from other cross-over dumps, it is also a fact that it has 50% fewer parts. It consists of two continuous rails to which are attached substantial horns, securely fastened to a heavy shaft; this shaft has a bell crank and quadrant with spring device securely attached to the one end, while at the other end is situated a brake-wheel and lever device for releasing the car after discharging its coal. In operation, the cars pass over the knuckle, the jar being absorbed by the spring. Automatically the car assumes the dumping position. After the coal is discharged the car is released by means of a lever (the only work of the operator), which allows the car to pass over the track by depressing the horns which automatically resume position for the next car. This is done by means of the spring, which is of sufficient strength to bring the horns into receiving position, together with the rotating action of quadrant by gravity. Ten cars may be discharged over this dump per minute so that its capacity is only limited by the activity of the man required in its operation. Its continuous rails make stoppage of operation due to derailment of cars an impossibility and also insure less breakage of coal and less wear and tear on cars; its simplicity of design and operation and its capacity make it most desirable for large as well as small mines. Its large dumping capacity is due to the quick and continuous action of the dump, shorter movement of the cars, and the increased safety in bringing loaded cars close to the dumping position. This is the only dump where the car maintains continuously its natural position throughout the operation. There is no break or hinge in the tracks to cause derailment of cars and blocking of the coal consequent thereto. As this dump occupies less space than other cross-over dumps, the cost of tipple building for housing is correspondingly reduced; less help is required because of simplicity and ease of control. A full working dump may be seen in operation at the plant of the Jeffrey Manufacturing Co., Columbus, Ohio; the Pruden Coal & Coke Co., Pruden, Tennessee; or the Pursglove Coal Mining Co., Stewartsville, Ohio. Further details may be had from the manufacturers, the Jeffrey Manufacturing Co., Columbus, Ohio.



Jeffrey-Griffith Car Dump.

ASPHALT, like most other products of petroleum, is increasing in importance. Oil asphaltum, which is the asphaltum residue, derived mainly from the oils of California and Texas, made up more than half of the 208,655 tons of asphaltum products in 1909, according to the U. S. Geological Survey.

BRISTOL'S COMPENSATED GAS-FILLED RECORDING THERMOMETERS

A new compensated gas-filled Bristol recording thermometer has recently been developed for recording the lower ranges of temperature, and found satisfactory in numerous tests. These thermometers are equipped with a patented compensating device which automatically corrects for changes of temperatnre at the recording instrument. Bristol's gas-filled, class III. recording thermometers are equipped with sensitive bulb and flexible capillary connecting tube and a patented pressure-tube, the sensitive bulb and flexible connecting-tube and spiral pressure-tube all being filled with an inert gas under pressure. Changes of temperature at the sensitive bulb cause corresponding changes in the pressure of the confined gas and these changes in pressure are measured and recorded by the instrument. The sensitive bulb is usually about 10 in. long and ¾ in. diam., and the volume of gas contained is very large in proportion to the volume in the fine capillary connecting-tube between the sensitive bulb and the recording instrument, this making the error due to changes of temperature along the connecting tube negligible.

COMMERCIAL PARAGRAPHS

F. G. MUDGETT, manager of the Horse Shoe and Diana mines of Coulterville, California, has been appointed field representative and salesman for the Pierce Amalgamator with the Pacific Coast as exclusive territory.

The MINE & SMELTER SUPPLY CO. announces the appointment of John P. Cosgro, formerly manager for Allis-Chalmers Co. for the Republic of Mexico, as resident manager of the Mexico Mine & Smelter Supply Co., Mexico City, D. F.

The KELLY FILTER PRESS CO. has installed eight of its presses in the new mill of the Veta Colorada Mining & Smelting Co., at Villa Escobedo, near Parral, Chihuahua, Mexico. There are now 20 of the Kelly filter-presses in service in Mexico.

The F. MAYER BOOT & SHOE CO., of Milwaukee, Wisconsin, reports a continuation of their excellent business of the past on their line of boots for miners and prospectors. For many years this company has made a specialty of this grade of footwear and now has facilities for making 9000 pairs of boots and shoes per day. They are prosecuting dealers who have unlawfully used their trade-mark of 'Martha Washington.' A Western branch is established with the Washington Shoe Mfg. Co., Seattle, Washington.

The GEO. E. DOW PUMPING ENGINE CO., of San Francisco, reports the following recent sales: Plumas Amalgamated Mines Co., San Francisco, one 12 by 20 by 12 horizontal simplex steam-driven air-compressor. Cia. de Aguas de Santa Ana, Santa Ana, Salvador, C. A., two 11 by 12 horizontal duplex piston pumps direct connected to two 40-hp. electric motors. Union Hollywood Water Co., Los Angeles, one 12 and 22 by 12 and 20 by 18 horizontal two-stage air-compressors, cross-compound. California Oilfields Ltd., San Francisco, one complete fuel oil-burning set, one 500 sq. ft. surface condensor, one 6½ by 9 by 10 horizontal air-pump, two 140-hp. water-tube boilers, one 12 and 22 by 10 and 18½ by 18, two-stage, cross-compound, steam-driven air-compressor, with Meyer cut-off valve gear, two 5¼ by 3½ by 5 boiler feed pumps, and one 16 and 24 by 5½ by 18 horizontal compound duplex crank and fly-wheel pumping engine.

TABLE OF CONTENTS

EDITORIAL

A HEAD-LINE in a contemporary reads "Gary Coke Ovens Fired". The natural question is, what for?

CHICAGO headquarters of the *Mining and Scientific Press* and *The Mining Magazine* are now at 734 Monadnock Building, where Mr. A. J. Bamford will be glad to welcome old and new friends.

ADDITIONAL competition in the oil business of the Pacific Coast is promised by entrance of Dutch interests closely affiliated with Shell Transportation. The Dutch have done well in the East India oilfields and will bring experience as well as capital to California.

SALE of the Risdon Iron Works to the United States Steel Corporation has been rumored in San Francisco this week. Additional building by the Steel Corporation would be heartily welcomed in the West, and acquirement of the plant and good-will of the Risdon company would introduce the new enterprise under the best of auspices.

COAL-LAND cases in Alaska are now up for final hearing in the Department of Interior at Washington before the Secretary, Mr. Walter L. Fisher. It is impossible to forecast the decision. We note with interest and approval that in event the case is decided against the claimants a bill is likely to be introduced into Congress reimbursing them for the money they have expended.

IN ELECTING James Furman Kemp a member at its meeting on April 20, the National Academy of Sciences honored itself as well as the new member. As a patient investigator whose lucid writings are illumined by the use of scientific imagination and brightened by a ready wit, no less than as a teacher with the priceless gift of inspiring others, his renown, like a good wine, "needs no bush."

EXACT DETAILS are the items most helpful in any description of a technical process, and in the account of the operation of the mill of the Goldfield Consolidated Mines Company, of which we print the first part in this issue, Mr. J. W. Hutchinson, the capable superintendent, is generous in supplying them. The article will, we are sure, be widely read, and with much interest.

ARREST of the alleged Los Angeles dynamiters has attracted wide attention. We regret to see that persistent efforts are evidently being made to try the case in the newspapers. The defense has employed an authorized publicity agent, and on the other side there has been no hesitation to come within the light of the calcium. We commend the reported statement of the prosecuting officers to the effect that he is not concerned with what public opinion in the case may be: "If we have the evidence, the men will be convicted. If not, they won't." It would

be well to remember that this is a trial, not of organized labor, but of dynamiters.

EASTERN members of the American Mining Congress are enthusiastically preparing for the fourteenth annual session, which is to be held in Chicago, October 23 to 28 inclusive. Mr. Charles M. Moderwell has been made chairman of the local committee, and the new directors of the Congress itself are Messrs. Carl Scholz, James Douglas, George W. E. Dorsey, and B. F. Bush. An earnest effort is to be made to bring together on a common platform the metal miners of the West and the coal men of the East. Among the latter Messrs. Moderwell, Scholz, and Bush are well known and influential, so that there is a substantial prospect of success.

ANNEXATION of Canada by the United States is occasionally proposed by some oratorical mischief-maker. A fair retort is the suggestion that Canada will solve Alaskan problems for us by buying that Territory. Fortunately there is the best of good feeling between Canadians and Americans, and when the reciprocity agreement now being debated goes into effect, the ties between the two countries will be even stronger. The United States is not likely ever to annex Canada, but we have already annexed a number of excellent Canadian mining engineers, and have a hearty welcome in reserve for any others who may prefer to come south.

MINING speculation is discussed informingly in a letter signed by 'A Director' in *The Mining Magazine* for April. The writer points out the real economic service performed by the brokers and exchanges, and the difficulties that lie in the way of those who would reduce the speculative element in mining. Probably honest speculation, if we may use the term, would find few to condemn it. But in America, at least, the rank frauds that have been perpetrated, and the palpable cases of 'rigging the market' that are tolerated even on the best exchanges, are what has led to general disapproval. The public has learned to doubt its ability to discriminate between honest optimism and purposeful obfuscation. Therefore business on the big exchanges is dull. Money piles up in the banks and is going into bonds, but stocks and speculative ventures find no support. Honesty is not only the best, but the necessary policy, if speculation is to become popular.

BURIED TREASURE, lost ships, lost wills, the golden fleece, the mythical pot of gold at the end of the rainbow, romance and mystery in whatever form, are forces of compelling power that never lose their interest. That this is true was shown again in the columns of the daily press recently, where were chronicled the operations of the Pieces of Eight Syndicate, formed at Glasgow to search for the treasure of the Spanish galleon *Florencia*, sunk in Torbermory bay in 1588, and of another party which has sailed on the *Stanley Dollar* to search for the Peruvian millions in gold and jewels buried by the perfidious Thompson on Cocos Island in 1835. The hard-headed man of business may perhaps sniff at such visionaries, but to us there is cheer in the thought that though these may fail in their quest there will be a never-ending succession of dreamers, with undaunted hearts, to search for the unknown, for it is to such that we owe the greatest achievements in science, art, literature—all that makes life really worth while.

> "Each stroke aright of toil and fight,
> That was, and that shall be,
> And hope too high wherefore we die
> Has birth and worth in thee."
>
> *(To the True Romance.)*

ORGANIZATION of a new technical society of mining engineers appears at first glance unwarranted, there being already a number of excellent institutions soliciting their support. A few brave spirits have remained undaunted and the American Metallurgical Society therefore starts out freighted with high ideals and good purposes. With Mr. Ernest A. Hersam as president, the organization is sure to accomplish good. Just how wide and permanent its influence will be remains to be seen. Like all human institutions, the Metallurgical Society will need to justify itself by its works. With the general purpose, the strengthening of the bond between Western engineers, we are in full sympathy; as to the need and the probable effectiveness of the agency chosen, there is room for difference of opinion. The Western Association of Technical Chemists and Metallurgists, after some years of able effort, recently withdrew from the field of publication. The excellent work done by the Denver society was widely recognized, but the effort failed to enlist general support. Whether our San Francisco friends, even with somewhat different methods, will be more successful, is at least doubtful.

THE ANGLO-AMERICAN arbitration treaty, though it has evoked but little comment, is without doubt the most significant event of the year. Providing, as it does, that for a period of five years all matters in dispute between Great Britain and the United States, without any exception, shall be submitted to The Hague tribunal for settlement, it exemplifies a change in international sentiment the importance of which can scarcely be overestimated. It is the first time that nations have agreed in advance to arbitrate disputes that may even involve points of national honor, and it is a startling proof that two of the peoples of the earth believe war to be fundamentally unnecessary. Not that there has been any probability or even possibility of war between the two nations, but there has been an unwillingness on the part of both, but more especially on the English side, to definitely disclaim the possibility of recourse to arms. The relations of the two nations have always been most friendly, so that the changed attitude marks a clearer recognition of the essential harmony of interests rather than any increase of goodwill. And it is to be hoped that better co-operation in Far Eastern polities may exemplify this harmony.

MEXICAN conditions continue bad. We publish elsewhere a review of the situation written by Mr. Alvin R. Kenner, who but recently returned from Mexico. Since his account was written, there have been disturbances at Mazatlan, Cuernavaca, Durango, and elsewhere. It is extremely difficult to say to what extent these represent the acts of organized revolutionists such as those with whom Mr. Kenner came into contact, and how much they reflect merely the brigandage that is always ready to develop when the power of government relaxes. Accounts from Mexico are conflicting. Another engineer, one long resident in the country and a particularly competent observer, writes us that he has but recently traveled the whole of Sinaloa and Sonora without inconvenience, and he imputes the trouble to unpreparedness of the Federal Government lulled to a feeling of security by long years of peace. The quarrel is, of course, for the Mexicans to settle. The concern of the United States is with keeping its own citizens in order. Negotiations looking toward peace are now being conducted by the Mexican Government and Madero, with excellent prospects of a satisfactory basis being reached. That peace and prosperity may soon return to our southern neighbors is our own most earnest wish. Mexico is a fair land, and the Mexican people have made great strides under a heavy handicap. That progress should be checked even temporarily is a matter of universal

regret, but the world's confidence in the ability of the Mexicans to solve their own problems remains unshaken.

COLORADO legislators are considering a bill amending the present law relating to mine inspection and especially designed to increase safety in coal mines. Following the serious accidents of last fall, the Governor appointed a commission to frame a bill, which, after material amendment, has now passed the lower house and is before the Senate. While requirements are made more rigorous, the act will need extensive revision before becoming a law if it is to accomplish its purpose. It is faulty in permitting employment in the mines of children twelve years of age, provided they can read and write the English language. The day for child labor in mines has passed, and it is particularly surprising to find a progressive State such as Colorado, maintaining such a provision. The bill also provides for safety appliances and rescue crews 'when convenient,' which, of course, makes the provision meaningless. Either such things are necessary and should be required, or they are merely advisable and the matter should be left to the discretion of the mine managers. In other particulars the bill is equally defective. Colorado would do better to pay more, secure the most competent inspectors possible, and give them a freer hand.

Copper and Zinc Mining

Copper and zinc have many uses in common and are often thought of together. As metals in the market, they are closely related, but contrast could scarcely be more striking than that between the copper-mining and zinc-mining industries, characteristic sketches of which appear in the Joplin letter, and the Arizona, Utah, and New York mining news of this issue. On the one hand is the story of the miner, who with home-made machinery impelled by a decrepit horse, has single-handed developed a profitable zinc mine; on the other, bits of description of mills handling 10,000 tons per day, others in which 1000 tons is treated by a single unit, and finally, of the refusal of a bid for a 50,000,000-pound lot of copper. There would seem to be no *a priori* reason why the mining of one metal should remain in the hands of the individual small-scale producer, while that of the other has steadily and now almost completely passed into the control of the large producers. How complete this transformation now is, in the case of copper, appears from a mere recital of the names of the more recent mines, Nevada Consolidated, Utah Copper, Ray Consolidated, Miami, Chino, Braden, and Cerro de Pasco. On the other hand, the great bulk of the zinc ore produced in the United States, and hence in the world, comes from small mines operated by men, many of whom began by taking a lease on a single acre, and gathering together such equipment as could best be assembled at night. The reason for this contrast lies deep, and exists in the fundamental characteristics of the two metals. Copper sells for two to four times the price of spelter, and as price in both metals is governed by supply and demand, copper must accordingly be either scarcer or more useful than zinc. There is little evidence that there is less of copper in the crust of the earth than there is of zinc. Indeed, the balance of evidence, slight as it admittedly is, would seem to point in the opposite direction. Copper, however, is capable of many uses denied zinc. Indeed, the latter is a metal of limited usefulness, and zinc smelters have had always the problem of creating a demand for their product. It can not be doubted, for example, that if zinc were equally as useful as copper in transmitting electric current, the price of copper would fall and that of zinc would rise. Taking conditions as they are, it is evident that in the case of a high-priced metal it is possible to make a profit from ores of a grade so low as to be unworkable in the case of a low-priced metal. Assuming equally perfect extraction, and in the case of copper and zinc the difference in efficiency of treatment processes is not nearly so important as it was formerly, it should be possible to handle five tons of rock to get the same weight of one metal as from one ton of rock in the other case, if the selling price of the first metal is five times that of the second. In a word, the higher price of copper makes it possible to work lower-grade ores. As is well known, lean ores are more common than rich, and occur in larger bodies. As a general rule, exceptions to which in case of copper and zinc are unimportant, rich ores characteristically shade by degrees into barren rock. Every increase in the price of metal or decrease in working costs, adds to the ore reserve in an ordinary copper mine. The great porphyry deposits at Bingham now mined with steam-shovels, were formerly worked for the copper found in much smaller and richer streaks running through the main deposit. Rock containing from 1½ to 2½ per cent copper has become an ore, whereas rock containing that much zinc is worthless except for concrete or road ballast. Considering especially the Joplin deposits, which are worked only for zinc and lead, and in which there is no gold and silver, there are, broadly, two types of deposits: (1) the rich irregular 'runs', and (2) the lean but regular sheet-ground. It was the 'runs' that made the district, and they still are the mainstay of its prosperity. The majority of these deposits lie near the surface, and once found, mining costs are surprisingly low. They contain 5 to 12 per cent of blende that is of high grade and is recoverable by simple processes in cheap plants. The leasing system, while it imposes a burden, makes it possible for men to take up mining who can command little or no capital. It is entirely possible for three or four men working on a simple 'grub-stake' to discover a deposit and develop a profitable mine. We have known $120,000 in dividends to be paid within eighteen months on an investment of less than $10,000. The risk, however, is large, for here, as always, rich ores are irregular; perplexing to find and difficult to follow. The sheet-ground deposits are much more regular, though even in mining them managers have their troubles. The grade is low, the content of the great horizontal beds of chert so far explored averaging 2 to 4 per cent. Mining costs in sheet-ground, because large-scale operations are possible, may be kept low, but the ore is difficult to mill, and the metallurgical losses are high. So far the sheet-ground mines, while contributing largely to the output and offering much encouragement for the future, have not been conspicuously profitable. There is a widespread feeling that the future of the Joplin district lies in the sheet-ground, and that it is to be a future of large-scale operations, low costs, and steady production. If so, it will inevitably be a future in which corporations representing many stockholders replace small partnerships and individual operators. Zinc mining will then become more like copper mining, but this is contingent upon a satisfactory price for spelter. In the long run this means that new uses must be found for the metal, since consumption *per capita* must be increased if zinc is to gain in price on other metals. Temporarily prices will be influenced by such incidents as the withdrawal of American buyers from Mexico because of the insurrection, but in the long run the price of ore will be governed by the demand for metal, and only those mines may work in which the grade of ore is sufficiently high to insure or promise profit. Improvement in technology gradually lowers the line that marks off ore from rock, but in zinc the possibilities in the direction of improvement have been discounted to an extent not generally recognized.

Operation of the Goldfield Consolidated Mill

By J. W. Hutchinson

CONSTRUCTION

As this article will be confined strictly to the operations at the plant, those interested in general conditions at Goldfield, Nevada, are referred to J. R. Finlay's 'Cost of Mining', T. A. Rickard's articles on Goldfield which appeared in the *Mining and Scientific Press* during 1908, and the report on the geology of the district by F. L. Ransome published by the U. S. Geological Survey. The details of construction of the 100-stamp mill and cyanide plant of this company have received publicity through Bulletin 1438 of the Allis-Chalmers Co., which is substantially correct. However, in this bulletin due credit is not given J. B. Fleming, of San Francisco, who was employed by the Goldfield Consolidated Mines Co. as mechanical engineer, and who drew up the specifications and general plans. On these specifications the Allis-Chalmers Co. bid and secured the contract for the crushing and transmission machinery and electrical apparatus. The engineers of the Allis-Chalmers Co. were not employed by the Mines company until the general plans were out and the contract had been let. This is mentioned for the sole purpose of rendering to Mr. Fleming publicly the credit which this company gives him.

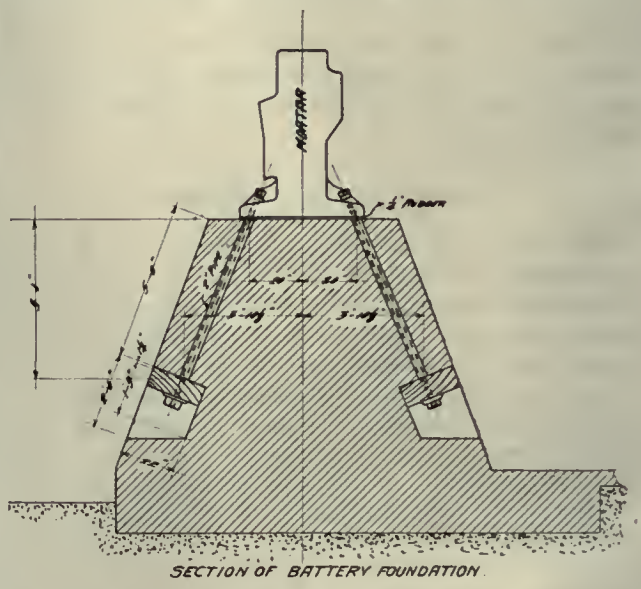
During the first year's operation, from December 26, 1908, to December 26, 1909, the stamps crushed through 12-mesh; the product, after classification, going to tube-mills. After the 20-stamp mill of this company, known as the Combination mill, was abandoned in September 1909, it was decided to increase the capacity of the 100-stamp mill from 600 to 850 tons per day.

The installation of 40 additional stamps, three tube-mills, and 25 concentrators was at first considered. This would have largely increased the floor space required, the structural steel for building, and, because of the contour of the hill, enormous concrete foundations for ore-bins and battery-block would have been needed. In addition, the increased tonnage could not have been handled for six months. The estimated cost of such construction was $175,000. As an alternate scheme, I proposed the using of six 6-ft. Chilean mills to be placed between the stamps and tube-mills. My idea was that 4-mesh screens could be used on the batteries, and a duty of 8.5 tons per stamp be obtained, followed by classification of the product, feeding oversize to the Chileans, crushing through 16-mesh, and finally, grinding this product in tube-mills after classification. This method was adopted and was in operation 90 days after the decision was reached. The total cost of the reconstruction, including 24 concentrating tables and many minor changes, was $75,000. No additional building was required. At the beginning of operations the ore was amalgamated at the batteries and below the tube-mills. With increasing depth in the mine the baseness of the ore rendered this operation unprofitable, and it was abandoned in September 1909 in favor of amalgamation of the concentrate prior to cyaniding. The floor-space occupied by the secondary amalgamating tables was used for the Chileans and concentrators and could not have been used for additional stamps and tube-mills. Doubtless a natural question here will be why the South African practice of using 4-mesh screens on the batteries and additional tube-mills was not adopted. This will be answered later.

To summarize: Through the expenditure of $75,000 the capacity of the plant was increased approximately 40%. To have accomplished the same result with stamps and tube-mills would have necessitated the expenditure of $175,000. To have added the requisite number of tube-mills to pulverize the 850 tons of 4-mesh product to 200-mesh would have increased the cost of construction over the Chilean-mill installation, and would have increased the cost of operation decidedly. Had 40 stamps and three tube-mills been put in, the cost of stamping and tube-milling would have remained the same on the increased tonnage; since the power, labor, and supplies would have increased in direct proportion. With the Chilean mills the additional labor for operating was five men. These would have been necessary in either case. For the Chilean mills 200 hp. is required. Stamps and tube-mills would have required 300 hp. The cost of supplies is approximately 2c. less per ton than for stamping and 3c. per ton for tube-milling. The total cost of pulverizing 80% of the mill-feed through 200-mesh is considerably less with three-stage reduction, as the following figures will show:

Two-Stage Reduction.	Cents.	*Three-Stage Reduction.*	Cents.
Stamping	22.1	Stamping	13.4
Tube-milling	20.6	Chilean-milling ...	10.0
		Tube-milling	16.6
Total	42.7	Total	40.0

I have gone into detail for the benefit of the 'doubting Thomases', many of whom have visited the plant and who have been unwilling to believe that Chilean mills could be operated at a cost even approximating 10c. per ton milled.



SECTION OF BATTERY FOUNDATION

In order to avoid controversy, it may be mentioned here that the above costs per ton will be masked in the yearly figures by the damage to the plant by fire. For three months of the year ended October 31, 1910, the plant operated with 70 stamps and three Chilean mills. However, the above figures are representative of normal conditions. The low cost of operating Chileans is accounted for by several factors: (1) The design and construction of the mills, which were furnished by the Trent Engineering Co. of Reno; they have been most satisfactory in every respect, both as to operation and repairs. Nothing wears out or breaks except the crushing-steel. The horse-power required is 35 each. The capacity in tons pulverized is approximately 75 tons each. (2) The size of the feed to, and discharge from, the mills. Chilean mills fed with 4-mesh and discharging 16-mesh product, work most satisfactorily and produce, even at this mesh, approximately 30% of −200 slime. (3) The character of the ore, which is fairly soft.

The third proposal was to install a sufficient number of tube-mills to handle 850 tons of ¼-in.-mesh battery-product. As above stated, the cost would have been more, since the mill building would have had to be enlarged, and, from the contour of the hill, much grading and filling necessitated. In addition, experience here has not corroborated that of the 'Mines Trials Committee' at Johannesburg which found that a tube-mill is most efficient when operating on three or four-mesh feed. I do not want to be misunderstood. I believe this to be true on the Rand, where a large percentage of the tube-mill produced is leached, and the difference in the ores doubtless accounts for the difference in results. None the less, I have not been able to produce a satisfactory tonnage of −200 slime from one 5 by 22-ft. tube-mill fed with 4-mesh product and operating under con-

ditions similar to the South African recommendations, nor have I been able to secure enough additional tonnage to compensate the increased horse-power when operating one mill at 32 instead of 27 revolutions per minute.

Conclusions based upon working tests on the Goldfield ore are: (1) 100 stamps, crushing through 4-mesh (0.18-in.) screens, yielding a tonnage of 8.5 tons per stamp, must be followed by ten 5 by 22-ft. tube-mills in order to obtain a −200 product; (2) 100 stamps, operated under above conditions and followed by six 6-ft. Chilean mills, crushing to 16-mesh will require five 5 by 22-ft. tube-mills to deliver a −200 product. This leaves the problem: Can six 6-ft. Chilean mills be operated more economically than five 5 by 22-ft. tube-mills? Operations here make me think so. The following figures may be of interest: In stamping Goldfield ore to 4-mesh, 20% of the discharge passes 200-mesh; of the remaining 80%, the Chilean mills will 'slime' 30%, or 24% of the whole. This leaves 56% to be handled by five tube-mills; all of which has passed a 16-mesh screen, and 80% of which will pass a 30-mesh. Expressed in tons, each mill is fed with 95 tons of this product. Now, by feeding 10 tube-mills direct from the battery with 4-mesh feed, 20% of which will pass a 200-mesh screen, each mill is required to handle 68 tons of 4-mesh feed. Based on figures derived from working tests, the comparative cost is as follows:

Two-Stage Reduction. 100 stamps followed by 10 tube-mills fed with 4-mesh battery-feed:	Cents.	*Three-Stage Reduction.* 100 stamps followed by 5 tube-mills fed with 16-mesh Chilean-mill product:	Cents.
Stamping	13.4	Stamping	13.4
Tube-milling	30.0	Chilean-milling	10.6
		Tube-milling	16.6
Total (per ton)	43.4	Total (per ton)	40.6

From this the deductions may be made that: (1) Ore may be reduced to 4-mesh in the stamp-battery more economically than to 12-mesh; (2) for the reduction of ore particles to 16-mesh, where 'all slime' is required, stamps, followed by Chilean mills are more efficient than stamps alone; (3) ore may be reduced to −200 mesh in the tube-mills more economically when the mill is fed with 16-mesh than when fed with 4-mesh.

There is one more point to be considered. On referring to the cost of installation, it will be seen that there was a saving of $103,000 in favor of putting in the Chilean mills. Assuming that the future cost of operating these mills will be 15c., an increase of 3c. per ton of ore milled over the cost of operating 140 stamps and 9 tube-mills, and assuming a yearly tonnage of 300,000 tons, it will take ten years operation, or the milling of 3,000,000 tons of ore, to offset this original saving. It is not believed that the cost will increase to this extent. Rolls and Chilean mills or other methods of comminution were not considered, for the simple reason that the problem was to increase the capacity of a 100-stamp mill, designed to deliver an 'all-slime' product to the cyanide plant. If this article invites discussion, I shall be glad to go into details more freely at some future time.

ELEMENTS OF COST IN OPERATION

Before passing to the detail of operations it may be well to enumerate the factors governing costs and efficiency.

Water.—Water for milling was supplied during the first two years operation entirely by the local water company, coming from the Palmetto range at Lida, nearly 30 miles distant. Recently the mine-water has been conserved and neutralized, and about one-fourth of that consumed is now supplied from the mines. The local company charges at the rate of 50c. per thousand gallons; the total water consumption per ton milled is 220 gallons, or 11c. per ton. This is a lower consumption of water than any wet-crushing mill on record so far as known. This item of cost is included in supplies.

Labor.—With the exception of two or three Slavs employed in roustabout work, the entire mill crew is American. The wage-scale is $3.50 per day of eight hours for ordinary labor; $4 to $4.50 for mill-men; $5 for machinists, electricians, and carpenters. Each man makes out his own time on a distribution slip, stating hours worked, department, and whether on operation or repairs, which slip, after being checked by the foreman on shift, is delivered to the timekeeper's office, where a daily distribution of labor is made after the following form:

GOLDFIELD CONSOLIDATED MILLING & TRANSPORTATION CO.

Total mill labor				
Concentrate plant				
Total labor				

The entire crew, under normal conditions, including all the superintendence, men on current construction, foremen, and others, consists of approximately 90 men. The average daily pay-roll is approximately $400, and the average daily wage, including superintendence, foremen, master mechanic, electricians, etc., $4.44. Labor per ton of ore milled is $0.46; tons milled per man on shift, 9.65.

Power.—Power is supplied by the Nevada-California Power Co. at a cost of $6 per horse-power month, based on 90% of the peak load.

The average power load at present is 1500 hp., equivalent to 1.73 hp. or 32c. per ton of ore milled. A segregation of this load for the first year is shown on a chart that will be printed in the continuation of this article. The campaign of construction which has been waged has left no time to devote to bring this up to date.

Supplies.—Supplies, as usual, constitute slightly more than 60% of the total mill-costs. Naturally the distance from bases of supplies, combined with discriminating freight rates, would make this cost higher than is usual for cyanide plants in the United States. In addition to

these factors is the exceeding baseness of the ore, which, during the second year's run has shown an increase of nearly two pounds of KCN per ton of ore milled. Had the cyanide consumption remained as low for the second year as for the first, the total cost for milling and cyaniding would have been $1.85 per ton instead of $2.12. The following table showing costs for the first three months of this fiscal year and for 1910 may be of interest:

	Nov. 1910.	Dec. 1910.	Jan. 1911.	1910 Average.
Labor	$0.46	$0.476	$0.445	$0.56
Supplies	1.24	1.285	1.263	1.25
Power	0.276	0.325	0.311	0.31
Total	$1.976	$2.086	$2.019	$2.12

In this connection it will not be amiss to note that $40 mill-heads warrant considerably higher costs than does the ore usually sent to a stamp-mill and cyanide plant, and in judging these costs the fact that the ore has averaged approximately $40 for two years, should be taken into consideration.

OPERATION

Storage and Crushing.—The plant is situated about two and one-third miles from the various working shafts, from which the ore is transported over the company's railroad to the crusher-bins in steel hopper-bottom cars of 50 tons capacity each. Originally a Blake-Dennison automatic inclined weighing machine was used. It was destroyed in the fire and replaced by a Fairbanks-Morse railroad scale, over which the cars pass en route to the crusher. The operation of weighing cars has added nothing to the working cost, and has been decidedly more satisfactory than the automatic machine in this situation, where there are such decided and sudden changes in temperature. The transportation of the ore does not come under the head of mill operations, but I shall give the cost for the benefit of those interested. These costs are based on the actual dry tons milled, which normally will average approximately 25,500 tons per month. The figures include all labor, supplies, and other items incident to transporting the ore, and mine and mill supplies, as well as the maintenance of rolling stock and roadbed.

	Nov. 1910. Cents.	Dec. 1910. Cents.	Jan. 1911. Cents.
Operation	10	6	3
Maintenance	5	5	7
Total	15	11	10

The crusher-bins, as well as the entire crusher-house and belt-way are built of wood and have a storage capacity of 800 tons. A shaker-feeder of the suspended type, driven from the main motor (150 hp.) feeds the primary crusher through rack-and-pinion ore-bin gates. The crusher is a 7½-K Gates. Set for 2½-in. product, it delivers the ore to a 48 by 14-ft. Gates type revolving trommel, with 1½-in. apertures, which delivers the undersize to a 26-in. inclined conveyor (Stephens-Adamson type) and the oversize to two No. 4K short-head crushers, set for 1½-in. product, from which the ore gravitates to above-mentioned 26-in. conveyor. Concave plates of manganese steel for the crushers last approximately seven months and crush 175,000 tons of ore. Maganese-steel screen-plates for the trommel lasted 27 months and screened 504,000 tons. The Stephens-Adamson inclined conveyor, set at an angle of 19° 54′ and 369 ft. between centres, delivers the ore to a horizontal conveyor and tripper which distributes the product to a battery storage-bin. This bin is flat bottomed and has a capacity of 4000 tons. The fire of April 8, 1910, destroyed the inclined conveyor, so it is not known what life the belt would have given. The horizontal conveyor has handled 500,000 tons, and will doubtless accomplish half that much more before it is discarded. The entire crushing and conveying system is operated for eight hours by three men, two in the crusher-house and one on the conveyors. They handle 850 to 900 tons.

The cost of crushing and conveying is as follows:

Tons per day	First 3 months 1911. 850	Year 1910. 850	Year 1909. 600
Labor (cents per ton)	2.1	4.3	3.0
Supplies	0.1	1.3	0.5
Power	1.6	1.5	1.8
Total	3.8	7.1	5.3

The high cost for 1910 is accounted for by the fire, which destroyed the conveyor system and necessitated the building of an inclined tramway from the battery-bin to crusher-house, and its operation for three months, during which time it was necessary to tram the ore in cars over the battery-bin. The 70 stamps which were not destroyed by fire, were dropping on ore supplied by this tramway in seven days and nine hours from the beginning of the fire.

Stamping.—As stated in the beginning, all details of construction have been published in Bulletin 1438 of the Allis-Chalmers Co., and in this article no attempt will be made to give such details except on new construction. Through rack-and-pinion ore-bin gates, from battery-bin, *via* Challenge feeders, the ore is fed to ten 10-stamp batteries, five right, and five left, with 1050-lb. stamps, dropping 108 times per minute through 7 inches. The stamp-weight is distributed as follows: boss, 252; shoe, 185; tappet, 169; stem (3½-in.), 444; total, 1050 lb. The 20 mortars (10,200 lb. weight, 14 in. thick through base) are of the narrow, rapid-discharge, improved Homestake type designed for this company by J. B. Fleming and built by the Allis-Chalmers Co. on his specifications. The cam-shaft for each ten stamps (of hammered iron) is of 6½-in. diameter. During the 27 months operation, not one cam-shaft has been broken. The guides originally furnished have been discarded in favor of the 'Conture' guide, designed and patented by A. F. Couture, the master mechanic at the plant. This guide consists of one piece cast-iron (or steel) sole-plate, with tapered sockets for receiving the taper-cored wedges through which the stems operate. The distinguishing feature of the guide is the four-side taper of the sockets and wedges, and the method of dovetailing which permits of the wedges being reversed when worn. The use of these guides has materially reduced the cost of operation and increased the efficiency of the stamps.

The one-piece mortar block of concrete (mixture 1:3:3) contains 850 cu. yd. Anchor bolts for mortar and post shoes are arranged as shown in the following sketch. It may be of interest to note that the concrete withstood the fire of April 8, which destroyed the refinery, store-house, conveyor-way, and twenty stamps. The heat at the mortars was so intense that when the stamps fell, the wrought-iron anchor bolts were drawn out to a fine point. The new equipment was erected on the same foundations with no repairs. There is no sign of serious cracking in the concrete.

One man on each shift feeds the stamps, and one head batteryman on day shift, with a helper, sets all tappets, turns stems, changes shoes and dies, and does all the repair work incident to operating. As amalgamation at the battery has been abandoned, the battery-feeder is alone on his floor, and under such conditions, it seems that 100 stamps is the economic unit for operation. By this it is not meant that total costs for a 140 or 150-stamp mill will not be less, but the actual operation of the stamps will be more, for the reason that while power and supplies will increase in direct proportion to the increased tonnage, labor for 140 or 150 stamps will increase abnormally. Power is supplied for each 20 stamps by one 50-hp. Bullock motor, belted to a counter-shaft underneath the floor. A rack-and-pinion belt-tightener between the bull-wheel (built-up wood pulley) and this line-shaft controls the power for each 10 stamps.

Chrome-steel cams, bosses, and shoes, and Pennington dies have proved the most satisfactory here. In 27 months only two chrome cams have been replaced. The following comparison of wear of battery-steel may be of interest:

Make.	Days wear.	Price per lb., cents.	Cost per ton ore, cents.
Shoes.			
Chrome (8-in.)	58	5.43	1.88
Midvale (10-in.)	73	6.00	2.00
Pennington (8-in)	57	5.97	1.91
Dies.			
Chrome (7-in.)	83	5.43	1.25
Midvale (7-in.)	78	6.00	1.30
Pennington (7-in.)	104	5.97	1.06
Tonopah (7-in.)	49	4.00	1.70

The total consumption of steel (shoes and dies) per ton of ore milled in 1909 was 0.98 lb. with a stamp-duty of six tons per stamp through 12-mesh (0.048-in.) screen; in 1910, 0.604 lb.; stamp-duty, 8.46 tons, through 4-mesh (0.18-inch).

The following is a record of time lost and causes thereof for the year 1910, and for three months of the present fiscal year:

Total time lost on account of	1911. Per cent.	1910. Per cent.
Power	0.84	0.70
Water	0.08	1.43
Shoes and dies	0.28	0.20
Screens	0.01	0.08
Stems	0.17	0.11
Chilean mills	0.17	0.55
Tube-mills	0.08	0.63
Cyanide plant	0.11	0.21
Miscellaneous	1.40	0.91
Cleaning bat. tank	...	0.55
Fire loss	...	7.91
Total	3.14	13.28

A comparison of sizing tests of the 12-mesh (1909) and 4-mesh (1910) product from the stamps is given below, but is of little value owing to the increasing softness of the ore with depth.

Battery discharge through 12-mesh 0.048-in. screen. Duty 6 tons per stamp.			Battery discharge through 4-mesh 0.18-in. screen. Duty 8.46 tons per stamp.

Through	200			20.0

Originally one 24-in. cone-classifier received the 12-mesh pulp from each battery of five stamps, the spigot product from it gravitating to Dorr classifiers, the overflow to concentrators. These 20 cones were discarded in favor of two 8-ft. cones, each taking the pulp from 50 stamps. The following is a comparison of the cost of stamping through 12-mesh and 4-mesh screens:

Table 1. Stamping through 12-mesh 0.048-in. screens. Duty 6 tons.	Cents.	Table 2. Normal Conditions.	Cents.	Table 3. Stamping through 4-mesh 0.18-in. screens. Duty 8.46 tons.	Cents.
Labor	8.9	Labor	6.6	Labor	3.9

Power	6.4	Power	8.0	Power	5.4
Total	22.1	Total	22.1	Total	13.4

The first and third tables have been taken from the yearly mill-records, and while the various items do not show the proportionate decrease, the total reduction in cost of operating is approximately what would be expected from a 40% increase in tonnage. Several factors besides the coarser crushing have reduced the labor cost in table 1 to the figure in table 3, such as the improved guides, completion of current construction work, etc. Likewise, supplies for 12-mesh stamping in table 1 are not exact, as 200 extra shoes and 200 extra dies, furnished with the plant, did not have to be charged to cost of operation. This is stated merely to avoid confusion, as the sum of the various items in table 1 checks table 2, which is an estimate of the cost of stamping through 12-mesh under normal conditions. The discrepancy between power costs in table 1 and tables 2 and 3 is due to the recent installation of a storage battery which absorbs the mine peaks and virtually puts the mill on a meter reading.

Regrinding.—The second aisle of the mill proper contains the regrinding apparatus, which is divided into two sections, each taking the pulp from 50 stamps. Each section consists of one 7-ft. spitzkasten, three L. C. Trent Chilean mills, one bucket elevator (originally one 54-in. Frenier sand pump), one 8-ft. cone classifier, one 4-ft. spitzkasten, three Dorr classifiers, three 5 by 22-ft. tube-mills, and nine No. 3 Deister concentrators. Each section is run by one man on shift and the entire floor is kept in repair by one machinist and one helper on the day shift. This, of course, does not include the re-lining of the tube-mills. The total pulp from the 50 stamps feeding each section, gravitates through wooden launders, lined with 1-in. cast plate (grade 1¾ to 12 in.), to the 7-ft. spitzkasten, overflow from which passes to the main concentrator floor, and spigot product to three 6-ft. Chilean mills. Power for driving these mills is supplied by one 100-hp. Bullock motor belted to an overhead line-shaft. Actual meter readings show that each mill requires 35 hp. to operate when pulverizing 75 tons per day through 30-mesh, and producing 30% of −200 slime from its total feed. When the capacity of the plant was increased to 850 tons, no additional settlers or dewaterers were put in, and for this reason it is impossible to attempt close classification ahead of the Chilean mills, as the additional water required for grinding in them would prohibit economic dewatering in the cyanide plant; hence a great deal of −30-mesh product is sent to the Chilean mills, but as they have proved to be fairly efficient 'slimers,' the work of the tube-mills is materially reduced, and the apparently poor practice is in reality good. The following is a typical sizing test of the product from the Chilean mills:

	Per cent.
Remaining on 10 mesh	Trace
" " 30 "	4.0
" " 50 "	10.0
" " 80 "	16.0
" " 100 "	9.0
" " 150 "	6.0
" " 200 "	6.0
Through 200 "	48.0
Loss	1.0
	100.0

Midvale rolled forged steel has demonstrated its superiority for use in the mills. The dies, 5¼ in. thick, last approximately 125 days; the roller shells, 4 in. thick, average 165 days. Total steel consumed per ton ore milled, 0.32 lb. Screens for a time threatened to become an item of serious expense, as it was impossible to obtain a life of more than six days from the best screens on the market. However, by inserting a strip of 4-mesh screen in the screen frame where the hardest wear fell, thus protecting the screens from unnecessary wear, their life has been doubled.

The cost per ton of operating the Chilean mills, including all repairs and upkeep, is as follows: Labor, 1.8; supplies, 4.1; power, 4.7; total, 10.6 cents.

The pulp from the Chilean mills gravitates to one 18-in. bucket elevator with 28-ft. centres, where it is joined by the tube-mill product, all of which is fed to one 8-ft. cone-classifier, in which partial dewatering is accomplished before passing to the Dorr classifiers. The overflow from this cone passes to the two-compartment 4-ft. spitzkasten, and the spigot product from the cone joins the spigot product from the first compartment en route to the Dorr classifiers. The spigot product from the second compartment feeds the nine No. 3 Deister concentrators put on this floor when the Chileans were added. The overflow from this spitzkasten, together with the overflow from the Dorr classifiers gravi-

tates through pipes to the main concentrator floor. Each Dorr machine handles approximately 110 tons of dry ore at a dilution of 3:1, delivering a slime product, 80% of which passes a 200-mesh screen, and a feed to the tube-mills as follows:

	Per cent.
Remaining on 10 mesh	8
" " 30 "	13
" " 50 "	12
" " 80 "	23
" " 100 "	18
" " 150 "	11
" " 200 "	7
Through 200 "	7
Loss	1
Total	100

The contained moisture is 30%, which is increased to 40% as it enters the mills. The cost of elevating and classifying is as follows, in cents per ton: Labor, 1.2; supplies, 0.5 power, 0.6; total, 2.3. Revere Rubber Co.'s 'Granite' elevator belt and malleable iron bucket lasted 14 months and elevated approximately 400,000 tons dry ore.

Tube-milling.—As stated, each regrinding section contains three 5 by 22-ft. tube-mills (Gates) of the spiral-scoop feed, trunnion-discharge, type. Each battery of three mills is supplied with power from one 200-hp. Bullock motor, belted to the line-shaft. Two of the three mills are belted from this line-shaft and controlled by friction clutches. The third is geared direct from the main shaft, and controlled by cut-off clutch coupling. There is no doubt that individual drives for each mill would be more satisfactory. With the present arrangement, the repairing of one clutch hangs up 50 stamps during the operation. Silex lining has been used since the beginning of operations. This lining lasts seven months and is renewed with the following items of expense:

LABOR

Removing and replacing manhole, removing end-liners	$11.88
Removing pebbles	3.75
Removing old lining	11.25
Re-lining	63.76
Replacing pebbles	7.50
Total labor	$98.14

SUPPLIES

Cast end-liners	$92.48
Silex, 17,710 lb. at 2.634c. per lb.	466.48
31 sacks cement at $1.10 per cwt.	34.10
Total supplies	593.06
Total cost	$691.20

The time involved is: Hours re-lining, 68; hours setting cement, 72; total hours lost, 140. While this is less time than is customary at other plants to allow the cement to set, there has never been any trouble on account of starting too soon. The silex consumed per ton of ore amounts to 6 lb.; the cost of re-lining per ton of ore milled is 2.3c.; the amount of Danish flint per ton of ore milled is 1.8 pounds.

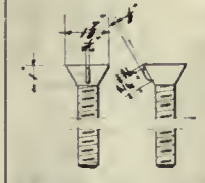
TOTAL COST OF TUBE-MILLING PER TON MILLED

Tonnage	850	850	600
Year	1911	1910	1909
	Cents.	Cents.	Cents.
Labor	1.4	2.1	2.6
Supplies	6.5	6.8	7.0
Power	8.7	9.7	11.0
Total	16.6	18.6	20.6

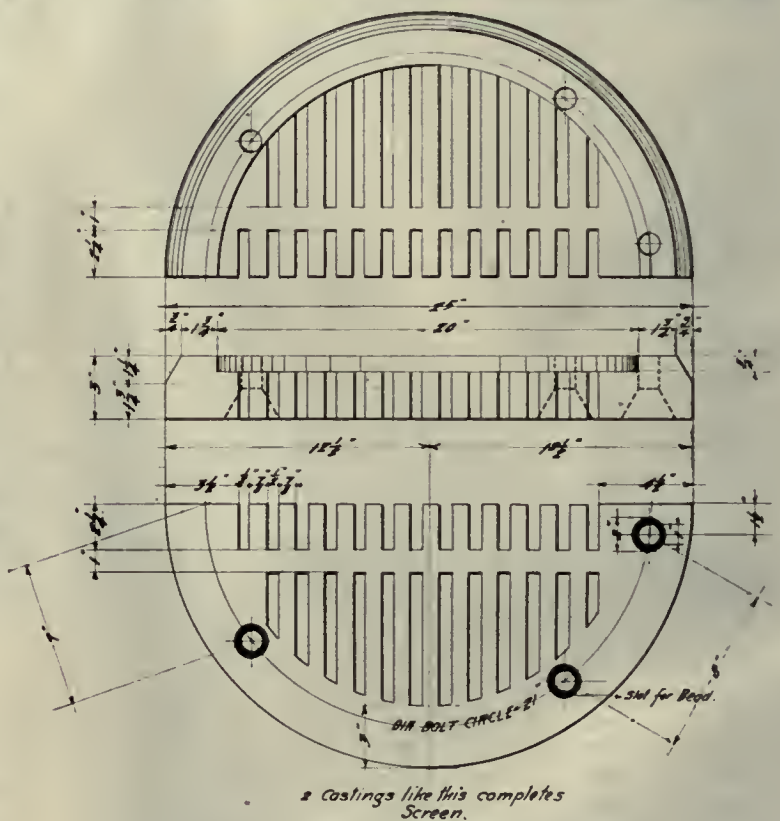
The design of the discharge screens on the tube-mill has been changed according to the following sketch, and the screens now last six months. The gears and pinions of manganese steel originally furnished with the mills are still in use after 27 months operation and will propably wear 12 months longer.

The product from the tube-mills is graded as follows:

	Per cent.
Plus 80 mesh	5.8
100 "	13.2
150 Mesh	11.6
200 "	17.8
Minus 200 "	50.6
Loss	11.0



Although the ore is classed as 'soft' ore, 40% of the product fed to the tube-mills is extremely hard quartz and is reduced to minus 200 product with difficulty. This was very noticeable when testing the mills with 4-mesh product from the batteries. The pulp discharged from the mills contains large quantities of coarse, rounded particles, which so accumulate after a few hours run that it becomes necessary to shut off the feed and grind the mills out.



CAST-IRON SCREEN FOR DISCHARGE END OF TUBE-MILLS.

After classification, the final product, which, as can be seen from the flow-sheet, is produced from two sources, the Dorr classifiers and spitzkasten, shows the following analysis:

	Per cent.
Plus 80 mesh	0.4
100 "	2.2
150 "	8.1
200 "	9.2
Minus 200 "	79.1
Loss	1.0
Concentration	100.0

(To be Continued)

NO CHROME IRON ORE has been produced in the Eastern States for many years, almost the entire production since 1880 coming from California. In 1909 the production of chrome ore, amounting to 598 long tons, came from California and Wyoming, the larger part being obtained from the latter State.

The Mexican Revolution

By Alvin R. Kenner

The first disturbances in Mexico, warnings of the present condition of affairs, began attracting attention in the early part of November, 1910. For the past four months foreign mining interests in Mexico have been making light of the revolution; influenced by 'things as they ought to be', rather than 'things as they are', they have minimized the trouble until the seriousness of the disorder has forced them to accept the situation as it exists and await the settlement of the trouble. Practically all the mines in the State of Chihuahua depending upon other than a local fuel supply, have suspended operations, and this is also true of a large portion of the mines in the State of Sonora. Farther south mining operations have not been interfered with enough to necessitate suspending operations, but should the Mexican Government refuse to recognize the demands of the *insurrectos* it is more than probable that within a short time mining will be as seriously inconvenienced in the south as it is at present in the north.

A Portion of General Blanco's Command; Insurgents.

Federal Troops, Tenth Cavalry, in Camp Near San Pedro, Chihuahua.

CAUSE OF THE REVOLUTION

It has long been an accepted fact that elections in Mexico are unfairly conducted. Following the re-election of Porfirio Diaz as president at the last general election, the Anti-Electionist party headed by Francisco I. Madero, protested the result and requested a new election. The proper legal steps were taken and the matter submitted to the Mexican Congress, but the report was never read, being dismissed with the comment that it was "too long." The action caused the present insurrection, and upon the inauguration of Diaz as president in September active preparations were secretly made by the Anti-Electionist party to obtain recognition by force of arms. Underneath this sequence of events that led to an actual crisis, was the general feeling of discontent in Mexico, an unrest that has been brewing for years, becoming stronger and more apparent as the people became more enlightened and alive to their own interests. A strong factor in awakening the people has been their contact with foreigners, noticeably Americans. The old story of taxation without representation is the underlying reason for this discontent. The bulk of the land in Mexico is owned by less than a hundred families. In Chihuahua the land is principally owned by the Del Rio and Terrazas families. Enrique Creel alone, a member of the latter family, is said to have owned at one time some 15,000,000 acres. These large estates or *haciendas* bear but a comparatively small proportion of the government taxes. If this land were subdivided and made productive, taxes on every-day necessities used by the average Mexican would be greatly lessened. It would ultimately mean greater independence, closely followed by a more intelligent people and a better class of citizens. At present the lower classes have little or no voice in the government.

No important objections are raised against the Mexican constitution. It is considered to be as fair and liberal as our own, but it has been grossly violated in the past, and, as stated by Madero, it is for "the constitution, general and free education, and poll rights" that the present rebellion is being waged. In addition to these demands, the insurgents hope to do away with the selection of governors by appointment and the *jefe politico* system. Under the Diaz administration very few governors or *jefes politicos* have

been residents of the districts they preside over, except in smaller and unimportant places. There are other grievances, local in character, which can only be remedied by striking at the government which permits them to exist. The words most frequently used by the revolutionists, those found in their speeches and printed matter, their slogan, as it were, are, "A Free Mexico and a Fair Election."

STRENGTH OF THE INSURRECTION

Although the date of the general uprising throughout the Republic was set for early in the fall, only a feeble and disappointing response rewarded the efforts of the leaders. This was due chiefly to three reasons: (1) The Government agents obtained information of the uprising several weeks before it was to be launched, and adopted severe measures with those whom it could connect with the movement. This created a reluctance among the Anti-Electionists to join an uprising the success of which seemed doubtful. (2) The plans of Madero were not widely known. Every endeavor was made to keep the plans secret, and only those known to be loyal to the cause were trusted. (3) The people were not sure of the sincerity of Madero. A member of an old, wealthy, feudal family, connected by blood and business relations with those high in the councils of the present administration, it is small wonder that many doubted the singleness of Madero's motives. Furthermore, many believe that Madero has not the qualifications of a leader. The worst that has been said of him, however, is that he is "a dreamer and a vegetarian" — perhaps his dreams are of a Free Mexico. As for being a vegetarian, it is a distinct asset in Mexican war times—many lower class Mexicans are vegetarians, more through force of circumstances than by choice, however.

Taking into consideration the unfavorable beginning due to the foregoing reasons, the armed force of 3000 men in northern Mexico, with possibly an equal number thoroughly prepared in the south, is an indication of what the future will bring in case the Government persists in trying to end the matter by force of arms. Recruits are slowly being added to the rebel force. The lack of education and absence of a free press in Mexico hinders the obtaining of recruits except by explaining to them in person the meaning of the insurrection and showing the probabilities of the success of the movement. The presence of an armed troop carries greater weight than hours of exhortation, and for this reason recruits have been mostly obtained from districts frequented by the *insurrectos*. Their success in the State of Chihuahua may be attributed to the higher order of intelligence of the people, who there receive better wages, dress according to American customs, and are decidedly different from the *waurache* type of peon found farther south. Great influence has also been wielded by Mexicans migrating from the American side of the border; their presence and assistance brought the insurrection from a feeble beginning to its present strength. Americans, also, of whom there are two hundred or more, have played a not unimportant part.

While the majority of Mexicans in arms are fighting for the principles advanced by Madero, many are actuated by personal grievances, the enumeration of which would fill a book. The foreigners, principally Americans, but a few Germans, come under two classes—one class including those of a socialistic turn of mind, to which the Germans mostly belong; the other class consisting of those who are out "just for the hell of it," as one American expressed the matter. The extreme and hopeful views of one socialist was evidenced in the remark, made by a German-American in a speech in front of the Candelaria Mining Co.: "We want all you Americans to join us; we are going to down the capitalists in Mexico, and then we'll cross the border and whip them in the States."

Putting aside the incentives that have brought these men together, it must be admitted that they are much in earnest, and that they will not be easily conquered. A fair degree of authority and organization is becoming apparent in their ranks, and as a whole they are by far the superior of any force, equal in number, that the Government will ever be able to put in the field against them. The Government troops are poorly fed. If there is a commissary department maintained, it is not in evidence, and no attempt is made to supply rations with any regularity. They usually depend upon the provisions to be obtained along the line of march. The Tenth Cavalry stopped at the Leon Camp of the Candelaria Mining Co. over night, and asked for food for the men and horses. They were given a feed of beans, rice, and a little bread, and ate ravenously. The men admitted that it was the best meal they had partaken of since leaving Guadalajara several months before. The *revoltosos*, on the other hand, have no trouble in getting sufficient supplies, being better acquainted with the country and having friends on every side; besides, they never miss an opportunity, when in the vicinity of any of Terraza's *haciendas*, to help themselves to the best of his cattle. The only Federal troops that can compare with the *insurrectos* are the pick of the Government *rurales*, and it remains to be seen whether they will equal them. Madero has shown one attribute of a leader—he is willing to consider the suggestions of others, and has an advisory staff composed of Col. Jose de la Luz Soto, Guiseppe Garibaldi (grandson of the great patriot Garibaldi), Eduardo Hay (a graduate in engineering at Notre Dame University), Capt. Alvarez Morales (a graduate of the Mexican Military School), and Capt. Manuel Vigil (a former Mexican Army officer). It is generally conceded that Madero is fighting for principles, regardless of what position he may obtain in the event of victory, and this is one cause of his strength.

BATTLES FOUGHT

In the beginning, the revolutionists avoided engagements with the Government troops on account of their lack of numbers; however, as they have gained strength they have adopted a more aggressive plan of campaign and have attacked the Federal troops, when not too completely outnumbered. Up to the present time most of the fighting has been confined to the border and along the line of the Mexico-Northwestern railroad which connects Juarez and Casas Grandes. A body of rebels, under the leadership of Blanco, was sent into Sonora for the purpose of obtaining recruits and getting in touch with the small bands existing there; a number of skirmishes took place, but of little importance. The *insurrectos* under leaders Orozco, Sanchez, Casillas, and Francisco Madero have confined their activities principally to that part of the country lying between Juarez, the city of Chihuahua, and Casas Grandes. Late in February Orozco threatened Juarez and demanded its surrender for the purpose, it is said, of misleading the Federals as to the real point of attack—the town of Casas Grandes. Much sport was made at Orozco's expense by the American press, because of his failure to do more than fire a few shots into Juarez. However, it is probable that he did not care to take Juarez then, as the Government would ultimately have concentrated a sufficient force to retake the city, which would have proved a serious setback to the cause.

On March 6 at daybreak the *insurrectos* under Madero attacked the town of Casas Grandes. The attacking rebels were about equal in number to the Federal garrison, but having reached some outlying adobe buildings under cover of darkness, the rebels more than held their own, and after several hours of fighting forced the garrison to hoist the white flag. At this crisis Colonel Cuellar arrived from La Ascension with 600 Federals and attacked the rebel forces in the rear; caught thus between two fires, the rebels retreated as quickly as possible. In this battle, which up to the recent fighting near Agua Prieta and Juarez, was the most important engagement during the insurrection, the rebel loss totaled 60, including those killed, captured, and unaccounted for. In this 60 are included the 16 foreigners, principally Americans, who were taken as prisoners to Casas Grandes. These sixteen men were well inside the town when the Federal reinforcements arrived and were unable to make their escape. The Federal losses were between two and three hundred. The exact number cannot be given. An American residing near Casas Grandes, and eye-witnesses of the battle, and the Mexicans who hauled out the dead, state that at least 250 Federals were killed.

The official Government report as given out stated their losses at 26 killed and the rebel loss at 100 killed and captured.

With the exception of the battle at Casas Grandes, the ambushing of the Federals at Galeana and Ojinaga, the engagement at Ures, Sonora, and the fighting near Agua Prieta, the other skirmishes have been of small importance. The rebels have practically cut off all communication and traffic on the Mexican Central and Mexican-Northwestern railroads, since early in February. Whenever an attempt was made to re-open either road the bridges were again burned, consequently no effort is now being made to run trains. The *insurrectos*, for the sake of foreign interests, agreed to permit railroads to run trains, providing they did not attempt to carry Federal troops. However, the Mexican Central is controlled by the Government, and the Northwestern, owned by the Pearson interests, was unable to prevent troops from riding on its trains, the Government taking matters into its own hands in spite of the protests of the Northwestern officials. Whether the *insurrectos* would have kept their promise or not is a question, as it is greatly to their advantage to cut off railroad communication, and by inconveniencing foreign interests makes an unpleasant situation for the Government. The result of hostilities up to the present is distinctly in favor of the revolutionists. Although many people still believe or rather hope that the trouble will yet be controlled by the Government, they are only those whose interests are suffering and who believe victory by the Government the quickest way to peace. Over 700 men, more than were killed on the American side during the Spanish-American war, have been killed in this insurrection, and this certainly makes it more than a guerrilla warfare.

EMPLOYEES OF THE CANDELARIA MINING CO., LEAVING THE MINE.

MINING OPERATIONS HINDERED

Mining has been more seriously interfered with than any other industry. The lack of railroad communication in that part of the country north of the city of Chihuahua has prevented the shipment of fuel, machinery, or supplies, and has stopped ore shipments. Express companies will not forward money for pay-rolls, nor will they assume the risk of handling bullion. Although many mine employees have joined the revolutionists, labor shortage has not so far proved a serious problem except in a few instances. The American Smelting & Refining Co. has suffered greatly—the smelter at El Paso drew a large part of its ore supply from mines on or adjacent to the Mexican Central and Northwestern railroads. This supply is now entirely shut off, and the smelter is running only four of its nine furnaces. Should the insurrection continue much longer, it is possible that the prices of lead and silver will be affected, although not materially unless hostilities extend to the south. Construction is being continued on the Pearson line between Pearson and Madero as long as provisions and supplies hold out. Ranching is being interfered with to the extent that the *insurrectos* will not allow, if they know it, cattle to be taken across the border, as is usually done for shipment.

The arrival of wagon-trains bringing Americans and Mexicans to the United States is a common sight in towns along the western division of the El Paso & Southwestern railroad where it follows the Mexican border. The first wagon-train sent to the border from the Candelaria mines on March 13 carried about 18 Americans and 75 Mexicans. It required four days to cover the distance of 130 miles, and although the trip was a rough one, the noise and laughter emanating from the American wagons gave no indication of the discomforts of the journey. The last camp was made near a watering place known as the 'three windmills' *(Tres Papalotes)*. During the night a child was born, but the mother and baby continued the trip and arrived in Columbus, New Mexico, with the rest of the caravan. The Americans argued that the child should be named 'Papalote'—or 'Papy' for short—but its parents will probably choose Francisco I. Madero Garcia, influenced more by the time than the place.

Both Insurrectionists and Federals have shown the utmost consideration for foreign property and foreign privileges. Mexicans are somewhat jealous of Americans as a class, but their jealousy is not so pronounced as to be the cause of violence to individuals. When it is remembered that some Americans merit shooting in times of peace for their attitude toward Mexican laborers, it is more surprising that in times of war there has been so little complaint. Americans, as individuals, are as well liked in Mexico as at home, but no better. In two instances a demand has been made on Americans for money. These instances were probably the acts of lawless Mexicans taking advantage of the unsettled condition of affairs. All supplies or provisions taken from foreign companies are paid for—often in cash by the Federals, and in the case of the *insurrectos* by means of a receipt which is to be eventually made good by the Government. Neither side would be likely to take supplies or provisions that were badly needed by any mining company. At the Candelaria mines the *insurrectos* helped themselves to ammunition, provisions, kerosene (the latter for burning bridges), and a supply of pipe fittings

for the purpose of making bombs; while the Federals took provisions only. Receipts were given or cash was paid for everything taken.

THE ATTITUDE OF THE U. S. GOVERNMENT

Much space has been given, in the American press, to the sending of U. S. troops to the border. Probably no one reason could be given as an explanation of the move. The desire to prepare for whatever might happen; the need to preserve the neutrality laws; the opportunity to test the new field-service regulations; the influence exerted by American capital interested in Mexico—all these, perhaps, had their influence in some degree. One explanation given by a disgusted cavalry lieutenant from an Eastern barracks to a very persistent Texas editor, was that "they came down to force Mexico to take back Texas."

Mistaken impressions exist as to how far the United States is warranted in interfering in Mexican affairs. The Monroe doctrine, in which many persons have been trying hard to find some excuse for interference, reads as follows: "The occasion has been judged proper for asserting as a principle in which the rights and interests of the United States are involved, that the American continents, by the free and independent position which they have assumed and maintain, are henceforth not to be considered as subjects for future colonization by any European power." How can anyone possibly find in these words the vestige of an excuse for hindering a revolution carried on in so fair a manner? The insurrection in Mexico is not to be considered in the same light as the intermittent disturbances in Central American republics. The latter are mere scrambles for power, fights are preferred to elections; but the *insurrectos* of Mexico are fighting for just principles and have more provocation than did the Southern States in our own Civil War. The United States did not undertake to protect foreign interests on the American continents when the Monroe doctrine was announced. It was merely a warning to foreign powers to allow the weak American Republics a chance to live. Many have gone so far as to say that we must settle the disorder in Mexico; that foreign powers expect it on account of the Monroe doctrine; that intervention in Cuba was a precedent which must be followed. The cases, however, are not parallel. The Monroe doctrine has no more to do with the Mexican situation than the ten commandments or the twelve principles of efficiency—in fact, not as much as the tenth commandment and the fifth principle. Should this false reasoning cause our Government to interfere in Mexican affairs other than as an arbitrator when so requested, it will be the rankest injustice to the people of Mexico. Peace commissioners would accomplish as much as armed intervention, and the results would be more lasting. Neutrality laws, as adopted at the second Hague peace conference, do not require the United States to prohibit "shipments of arms and ammunition" across the border, and only necessitate the detention of any "armed force" in the nature of "a military expedition." Nor are the Government troops prohibiting the "shipments of arms and ammunition," though they regard one armed man as a "military expedition" and are enforcing this interpretation of the neutrality laws with a severity that would hurt were the circumstances reversed.

THE FUTURE OUTCOME

The insurrection has brought to light much antagonism to President Diaz, and statements derogatory to the administration have been frequent and convincing. In spite of all that has been said, one cannot refrain from admiring him, and great credit is due him for all he has done for Mexico. Nearly three-fourths of Mexico's 16,000,000 inhabitants are of the peon class and can neither read nor write. It is not to this class the revolutionists or the Government can look for effective assistance. They will stand idly by, almost indifferent to the outcome; they apparently have no desire to better their condition and seem possessed of so deadly an indifference to their own welfare that the task of overcoming this inertia is grave and baffling. The most progressive modern reformer would throw up his hands in despair, and it is small wonder that so little has been accomplished by a man over 80 years of age, a warrior gaining his position by force of arms. Weighing the possibility and probability of graft were the ruling power in our own land in the hands of one faction for 35 years, it is remarkable that the Diaz administration has been apparently so free from it. Diaz, however, has been in power too long; his policies have served their purpose, and a newer, younger viewpoint is needed.

It is always difficult to generalize about Mexico. Under the present circumstances it is dangerous. A week may chronicle events contradictory to any specific prediction. However, barring internal wrangling and disagreements among the *insurrectos* themselves, the chances for peace in Mexico, except through arbitration or outside intervention, seem exceedingly remote. So far the *revoltosos* have had the best of the struggle, and they were never better prepared to carry it on than at present. As the insurrection grows older they are gaining in numbers and organization.

The invasion of Mexico by foreign capital undoubtedly had much to do with delaying the present crisis. The remunerative employment given to thousands of laborers has relieved conditions that would otherwise, years ago, have been felt too severely to have been endured. Intelligent Mexicans, who would otherwise be heart and soul with the revolution, are against it for no other reason than that they bid fair to lose most remunerative positions due to the closing down of foreign properties by the insurrection. It has been hinted that American capital financed the revolution. It does not seem plausible, and no proof has been given. However, it is likely that American capital will have much to do with putting an end to it. Many of the officials high in the Diaz administration are closely associated in a financial way with American capitalists interested in Mexico. Great pressure can be brought to bear on the Government and the rebels will agree to any fair proposals. Consequently we may look to Eastern financial interests to bring about peace, if Mr. Dooley is right when he says: "The capital in Mexico, me boy, isn't Mexico City. It's just south of Canal street in th' city of New York."

Feldspar for Fertilizer

Much interest has recently been aroused in the use of potash feldspar as a fertilizer. Potash is an important plant food, which, in fertilizers, has usually been supplied in the form of wood ashes or imported from Germany in easily soluble potash salts (sulphate, carbonate, or chloride). The Department of Agriculture has recently made experiments to determine the availability of finely ground potash feldspar as a substitute for the more soluble potash salts. The evidence so far obtained appears to indicate that under certain conditions and with certain crops feldspar can be made useful if it is ground sufficiently fine. On the other hand, it is highly probable that under other conditions the addition of ground feldspar to the land would be a useless waste of money. At the present stage of the investigation it would be extremely unwise for anyone to attempt to use ground rock, except on an experimental scale that would not entail great financial loss.

If further experiment shows that ground feldspar can be used as a fertilizer, it will undoubtedly lead to the utilization of much pegmatite which, because of too fine grain or too large a percentage of quartz or of iron-bearing minerals, is not valuable as a source of pottery material. Many deposits of this kind are near railroads. An equally important result will be the utilization of much material that is now discarded at feldspar quarries.

A number of processes have been patented in this country for the dissociation of potash feldspar to obtain the more readily soluble potash salts, but none of these have yet been applied on a commercial scale.—*U. S. Geol. Survey.*

A NEW EMERALD locality has been discovered in North Carolina, where promising gems have been found on the surface in a cotton field. The crystals are rather large and are of a deep green color.

Orange Free State Goldfields

By Rowland Gascoyne

During the last twelve months the interest in the Orange Free State goldfields has been revived on account of the Consolidated Gold Fields of South Africa, the Free State Development Co. Ltd., and others acquiring considerable areas of ground on option, carrying the outcrops of the Witwatersrand system, accompanied by several outcropping auriferous reefs.

The interest was materially increased when it was made known that G. S. Corstorphine, one of the leading geologists on the Rand, had reported to the effect that past prospecting operations on these Free State properties had not been conducted in such a manner as to be of any convincing value, so there was still a possibility of finding the Main Reef series, and if that proved to be barren or lean there was still a prospect that some of the other outcropping reefs might yield a mine. He had no difficulty in recognizing practically all the markers so well known on the Rand, and the hopes of those interested in these Free State farms encircling the town of Parys went up considerably by virtue of this encouraging report. On his advice the Consolidated Gold Fields of South Africa took options on a number of farms and in company with the Free State Development Ltd. engaged Mr. Corstorphine to superintend the prospecting operations.

Now this goldfield, known as the Venterskroon goldfield, has a remarkable history, extending over a period of twenty years. It is the only place due south of the richest section of the well known Witwatersrand goldfields where the Rand rocks, after disappearing beneath the newer formations, come again to the surface. At this particular spot the Witwatersrand system is remarkably well developed, carries all the well known divisions characteristic of the Rand, and likewise several reefs. The beds of the Witwatersrand system are in places tilted beyond the vertical and all around the granite boss the beds outcrop concentrically in proper geological sequence. Molengraaf, Draper, and every geologist who has inspected this area have been much struck by the above facts and the remarkable and well developed manner in which the whole of the Witwatersrand system appears to have been reproduced here. Almost ever since the discovery of the Rand this field has attracted geologists and prospectors, but the reefs when followed prove patchy and where carrying good ore seem soon to pinch out at depth. The fact, however, that Mr. Corstorphine was fairly sanguine of success and was prepared to attempt the finding of ore on what he considered new and proper grounds, gave rise to considerable hope and confidence. Had he sought counsel from those who had experienced disappointment in this goldfield, Mr. Corstorphine might perhaps have hesitated somewhat in preparing such an encouraging report. However, about a year ago prospecting operations were commenced in earnest with the primary object of establishing the existence of the Main Reef series, and, failing that, to discover some other conglomerate reef carrying sufficient gold to justify the commencement of mining operations. Recently, under date of March 4, a report on the work done was published. In trenching across what Mr. Corstorphine regarded as the Main Reef zone, he came across an unexpected igneous intrusion and a deposit of Karoo sandstone overlying the Witwatersrand beds. In fact, the whole area where the Main Reef series might be expected to occur, was occupied by such an extensive deposit of diabase as to make it impossible for any conglomerate reef to exist there. Trenches cut on either side of supposed Main Reef series horizon also showed nothing of value, and inspection of other reefs showed them to be so poorly developed that it was not considered prudent to spend money ascertaining their value. Boring was then undertaken in order to intersect the Main Reef horizon in depth, but again diabase intrusions were found, and Mr. Corstorphine came to the conclusion that in what he considered the geological horizon of the Main Reef series no profitable reefs are present and among the other reefs outcropping in the goldfield there is little hope of finding one that is profitable. He has confirmed the opinion of other geologists and engineers who had preceded him in the same task, although they may not have prospected on the same scientific and geological lines. His assistant, however, reports that these diabase intrusions rapidly thin toward the south, and it may be that in a southerly direction they disappear altogether. Whether the Main Reef series reappears again in its supposed horizon to the south, remains to be seen. It must not be forgotten, however, that at the outset Mr. Corstorphine has only prospected less than one-half of the Venterskroon goldfield. There still remains the westerly portion upon which the Free State Rand Ltd. is just commencing active prospecting operations.

This failure of the extension due south of the richest section of the Witwatersrand goldfield throws but little additional light of any value upon the behavior of the Rand bankets in depth, on account of its distance of nearly forty miles from the best Rand outcrop mines, a distance sufficient under the varying conditions of the banket reefs to allow several goldfields to reappear and as quickly disappear again.

For the last five years the New Rand Ltd. has also been looking for the Main Reef series in the Free State about thirty miles to the east of the operations carried on by the Free State Development Co., and the Consolidated Gold Fields of South Africa. Here the conditions are somewhat different from those surrounding the Vredefort granite boss, the Witwatersrand system dipping south at an angle of 30°, apparently as the result of an east to west antiecline running between the Heidelberg and Free State Witwatersrand deposits. The New Rand Ltd., with boring operations, has followed the Lower Rand beds to the south until the consulting geologist has arrived at the opinion that he has struck, in No. 9 bore-hole, the red bar marker so well known on the Central Rand as the indicator to the position of the Main Reef horizon. Since that indicator was struck, four other holes have been put down without striking the Main Reef series, so that the value of the alleged marker may be considered as at a considerable discount. The sites of these four bore-holes do not seem to be well chosen and little new ground has been proved.

Briefly, then, it may be said that in the Orange Free State, which offers the most inducement to prospectors in looking for the extension of the great Rand goldfield, nothing but disappointment has yet been met, and the opinion is gaining ground that the prospects of finding another Rand in South Africa are decidedly unpromising.

Magnetic Concentration and Briquetting

The low-grade magnetite ores of central Sweden are now being concentrated on a considerable scale, according to H. V. Winchell. The process most favored in that country is called the Gröndal process, from its inventor. The raw ore, containing from 27 to 55% of iron, is broken in a crusher, and ground to sand in a ball-mill. The magnetite sand or concentrate, containing 67 to 71% iron, is taken out by magnetic separation, moistened and molded into bricks about 6 in. square and 2½ thick. No binder is used. The bricks are simply pressed and moved slowly on iron conveyors through a furnace heated with generator and furnace gases and subjected to an oxidizing flame at the temperature of about 1400°C., or considerably above the sintering heat. In these furnaces the magnetite is changed to hematite, the percentage of sulphur is lowered, and a hard porous briquette is made, suitable for the blast-furnace. By this process, at a cost of about 80c. per ton, some 27 Gröndal furnaces are turning out about 300,000 tons of briquettes per annum. Since magnetite briquettes require about 300 lb. of charcoal per ton of pig iron more than those made of hematite, the expense of the briquetting is justified in a region of high sulphur magnetite ores. This process is of special interest in Minnesota because of the large quantity of low-grade magnetite ores on the eastern end of the Mesabi range, at present unmerchantable.

Developments in Illinois Oilfields

By H. A. Wheeler

THE EASTERN FIELDS

*The eastern Illinois oilfield extends southwest from Westfield, in the northern part of Clark county, through Crawford and Lawrence counties, Illinois, to Princeton and Oakland in Gibson county, Indiana. There are slight lateral extensions to the westward in Coles, Cumberland, and Jasper counties. It has a length of 90 miles and a width that varies from one to ten miles and averages three to four miles. A few gaps still break the continuity, although these have steadily diminished in size and number as the field is re-drilled. Such a remarkable length and width, coupled with the richness and number of oil-producing sands already found, without considering deeper sands that geology almost assures, makes this the richest oilfield ever opened in the history of the industry. While individual wells and local enrichment in other fields have exceeded the Illinois record, no other field has shown such a high average

Map Showing Position of Eastern Illinois Oilfields.

richness over such a remarkably large area, nor have others ever reached an output of 35,000,000 bbl. in six years.

At the northern end, or Casey district, there are two producing sands at about 400 and 600 ft., and the belt is two to five miles wide. While the wells have not been large, the drilling is so inexpensive that it has proved highly profitable. Like most shallow sands, they are not proving long-lived, and little development was going on until a recent discovery was made at 2900 ft. The latter is the deepest production in Illinois, but it is too early to determine its magnitude. The shallow wells cost $800 to $1200 complete, which includes the drilling, casing, shooting, tubing, tankage, pumps, and so forth.

The central portion of the field is in Crawford county, with Robinson as the centre, where there are three sands at 750 to 1100 ft., although most of the production is obtained from about 950 ft. This has been an exceedingly rich district and has made many fortunes, as the field has a width of three to ten miles, and it attained a daily output of 100,000 bbl. by its third year. Like the Casey district, the drilling can be done with portable rigs at a large saving over the use of derricks, and the contract prices of $1.25 to $1.50 that formerly prevailed have been reduced to the very reasonable rates of 70 to 80c. per foot. The cost of a well, complete and put to pumping, ranges from $1200 to $2500.

The southern portion of the field is in Lawrence county, with Bridgeport as its centre, and while this is the deepest part of the field, it yields by far the richest and has the best grades of oil. The belt is two to six miles wide, and to date seven pay-sands have been found that range from 800 to 1950 ft. in depth. The McCloskey or 1950-ft. sand that was discovered last year is the deepest and richest thus far found, as it produces wells up to 3000 bbl. daily output. While the growth of this district has been slower, from the greater depth and expense of the wells, the daily output exceeds 60,000 bbl. and the older wells are holding up remarkably well. Drilling costs from $1 to $1.50 per foot, as caving ground requires more or less under-reaming. The cost of a well, complete, ranges from $2500 to $3500 in the shallower sands, and from $4000 to $7000 in the deeper sands.

MARKET CONDITIONS

An 8-in. pipe-line was built into the field in 1906, and there are now five pipe-lines; three, 8-in.; one, 12-in.; and one, 6-in. These have a combined capacity of about 110,000 bbl. and transport the oil to the large refining centres at Wood river, near St. Louis, 140 miles; to Whiting, Indiana, 200 miles; and to the Atlantic seaboard, 900 miles. About 900 steel tanks, of 35,000 bbl. capacity, are scattered through the field, which provide storage for about 30,000,000, and which have enabled the buyers to take care of production without the usual slaughtering of prices.

The oil has sold at 60c. per barrel, except a small amount under 30°B. that brings 52c. While this is a low price for such a high-grade refining oil, it is a much higher price than any other field ever enjoyed during its development or flush stage, when production always greatly outstrips the shipping facilities. Other fields have had to accept 3 to 25c. per barrel during the early stage while awaiting the advent of the costly pipe-lines that are required to handle and economically transport a large production. As the pipe-line facilities are now able to care for the output and are drawing on the surplus at the rate of 250,000 bbl. per month, higher prices should soon rule, and recover not only the former price of 82c., but eventually reach $1 to $1.10 per barrel, which the paraffine base and excellent gravity of the oil warrants. The oil ranges from 32 to 39°B. in gravity, except a small amount of shallow oil that is 28 to 30° Beaumé.

While ample gas occurs with the oil to operate the drills and pumps and furnish the adjoining towns, no large quantities have been found thus far that are commensurate with its importance as an oilfield. That larger and stronger gas wells will be found in the deeper sands that have not yet been prospected is quite probable, and gas lines from this field may yet supply St. Louis and Chicago.

WESTERN ILLINOIS

In its early history, western Illinois was of considerably greater importance than eastern Illinois. Gas was found in commercial quantities at Litchfield in 1882 and lubricating oil was produced there for about twenty years. Sparta enjoyed gas for several years after its discovery in 1887, and since 1907 it has produced some excellent refining oil; while the Pike county gasfield has supplied the local farmers since 1890. The present production of western Illinois, however, is scarcely over a year old, and started from the accidental discovery of oil in a new coal shaft at Centralia in the autumn of 1908. Subsequent drilling developed a few small wells at a depth of 600 ft. in the immediate neighborhood. In prospecting 4½ miles north for the extension of this sand in 1909, at Sandoval (60 miles east of St. Louis) it was found dry; but on continuing the drilling to 140 ft., a 40-bbl. well (Fox No. 1) was brought in. On drilling (Fox No. 2) on the adjoining farm, the 1400-ft. or Stein sand, was found dry; but on continuing the drilling, a 350-bbl. gusher was struck at 1525 ft. in the Benoist sand that also yielded 5,000,000 cu. ft. of gas daily. A dry season prevented much drilling that year, but in 1910 a rich oil pool was opened that today is two miles long by a

*Read at the St. Louis Engineers Club.

mile wide, and on which there are 40 wells that had an average initial output of 118 bbl. daily. This is the highest average yield of any pool in the State, according to the Illinois Geological Survey. The oil is obtained from the base of the coal measures. The Stein or 1400-ft. sand is found to yield 40 to 60-bbl. wells over much of the area, but at present this is cased off to go 150 ft. deeper to the richer Benoist sand. Field pipe-lines convey the oil to loading racks of the Indian Refining Co. (independent) on the Baltimore & Ohio Southwestern railroad, or to that of the Ohio Oil Co.'s (Standard) on the Illinois Central railroad. Last fall a 6-in. pipe-line was built into the field, so that adequate shipping facilities are now afforded the output. The grade of oil is about the same as in Lawrence county (gravity about 36°B.) and sells for 60c. per barrel at the wells.

The work of the Illinois Geological Survey shows that the Sandoval field is on an uplift that extends south to DuQuoin and considerable prospecting is now going on along this promising zone, which passes through Centralia. Further drilling into the deeper sands at Centralia brought in several wells recently in the Benoist sand; but as it is not so thick, they have not thus far proved as rich as at Sandoval. Drilling in the latter part of 1909 discovered gas at a depth of about 400 ft. near Carlinville, 55 miles northeast of St. Louis, that is being used at that town for lighting and heating. Drilling at Greenville, 50 miles east of St. Louis, in Bond county, in December 1909 discovered a good gas-sand at 950 ft. There are now several wells yielding 1,000,000 to 2,000,000 cu. ft. of gas daily, that supply Greenville (5000) with gas for heating and lighting at 25c. per 1000 ft. This sand is at or near the base of the coal measures. Drilling last autumn at Old Ripley, in the western part of Bond county, discovered oil at a depth of about 2000 ft. that is of good grade, having a gravity of 39°B. It has been difficult to get reliable information about this well, as the company that made the discovery is absorbing all the leases in the neighborhood, but the well seems to have a capacity of 25 to 50 bbl. Other wells are drilling in the neighborhood and the oil horizon seems to be in the Devonian horizon, or below the coal measure.

In prospecting this winter for a lower vein of coal with a diamond-drill at Livingstone, 35 miles northeast of St. Louis, in Madison county, a strong flow of gas was struck in a thick sand at 581 ft. To the fact that the drillers were badly burned and the outfit set on fire was due the publication of this discovery. The gas is issuing with a roar from a 3-in. hole and the open pressure is at least 80 to 100 lb.; if closed in, it would probably show a rock-pressure of over 200 lb., but the fear of the gas getting into the mine has prevented its utilization and it is allowed to blow off and burn as a huge torch that can be seen for miles at night. The attention of the oil-men has not yet been directed to this accidental discovery, which is quite as important in pointing to an oilfield, as it proves the occurrence of a valuable gas sand, while the deeper sands are likely to be much richer. While this paper is being written, a paying oil well is reported near Carlyle, in Clinton county and directly south of Greenville. A little oil was found there last summer at about 1000 ft., and if the above proves correct, it was probably an edge well and the pool has now been found.

Dredging Costs

Part of the main canal of the Los Angeles aqueduct through Owens valley is being excavated by means of a dredge. This consists of the working part of a Marion No. 60 electric shovel, with a dipper of 1½-cu. yd. capacity, mounted on a scow. The dredge was built on specifications furnished by engineers of the aqueduct, and cost, exclusive of freight, $19,897. The material handled is valley soil, and the work is easy. In many particulars it differs from that involved in gold-dredging, but the following costs, for the month of February 1911, and totals to date, are of interest. The engineer in immediate charge is A. Swanson. H. A. Van Norman is in charge of the division.

DREDGING COSTS, FEBRUARY 1911, LOS ANGELES AQUEDUCT

* Yardage based on theoretical section of 14.81 cubic yards per foot. The section is somewhat exceeded in places on account of excess cut.

Air-Lift Agitation of Slime Pulp

It may not be generally known, but the air-lift for agitation of slime has been in use in the Transvaal for some time, and perhaps it may be of interest to give a brief account of the progress made on the Rand with this process, where, however, the decantation system continues largely in vogue. At a recent meeting of the Chemical and Metallurgical Society of South Africa, Robert Allan dealt with the subject and related the experience and results of trials in several countries and also the progress made during the last thirteen years on the Rand.

It was W. A. Caldecott, writing upon the chemical condition existing in accumulated slime, who showed how the neutralization of cyanicides would be effected by their gradual oxidation through exposure to air, and in March 1898, in conjunction with John Kelly, he took out a Transvaal patent, No. 1559, for an air-lift apparatus for the agitation and aeration of slime pulp or other gold-bearing material. This method of sweetening accumulated slime by means of atmospheric oxygen is utilized on the Geldenhuis Deep G. M. Co.'s plant and also on that of the Luipaard's Vlei Estate & G. M. Company.

The first company in the Transvaal on record as using the air-lift in the treatment of accumulated slime was the Nourse Mines, Ltd.; a flat-bottomed tank 30 ft. diam. and 12 ft. deep being used. The Geldenhuis Deep G. M. Co. uses two conical-bottomed vats, each 20 ft. diam. and 20 ft. deep, to oxidize accumulated slime, the vertical depth of the cone being 5 ft. These vats have air-lift pipes 16 in. diam. in the lower portions of the vat, of one-half the depth only. Pipes were formerly used in length equal to the full depth of the vat, and afterward shorter lengths were tried with much more satisfactory results. The slime was pulped with two parts of water in a knife-box mixer and then pumped into the air-lift vats, a charge for each tank being 50 tons of dry slime.

Each vat requires 50 ft. of free air, compressed to 10-lb. pressure, per minute. At the plant of the Luipaard's Vlei Estate Co. the accumulated slime after being suitably pulped (lime and lead acetate being then added) is pumped into a conical-bottom vat of 30 ft. diam., fitted with an air-lift pipe 18 in. diam, 26 ft. high, and 22 in. above the bottom of the vat. The air supply to the air-lift is delivered through a ¾-in. air-pipe, centrally placed inside the lift pipe. This supply is utilized only when the vat is full and its contents are in agitation, but when the vat is being filled or discharged the air-lift is not operated, the pulp being agitated by air supplied through four ½-in. air-pipes outside the air-lift tube. The pulp receives a total aeration of 22 hours as follows: Filling 9 hours (incomplete aeration), air-lift agitation 6½ hours, discharging (incomplete aeration) 7 hours. The charge of the vat is 150 tons of slime and 300 tons of water and this charge is probably the largest single charge of slime that is agitated anywhere. The vat requires about 85 cu. ft. of free air, compressed to between 25 and 30 lb. per square inch. The small amount of sand, which is always present in accumulated slime, is drawn off from the bottom of the cone, as in the separating cone of the laboratory, and sent to the tailing wheel of the cyanide plant. One of the most useful parts of the treatment vat is a conical diaphragm surrounding the air-lift pipe, whose horizontal base is 3 ft. 4½ in. above the bottom of the vat. This leaves an annular space about 9 in. wide between the diaphragm and the sloping side of the vat, through which the pulp passes to the air-lift. This arrangement entirely prevents the banking up of material around the mouth of the air-lift, and reduces the chance of fine sand collecting on the sloping side of the vat above the diaphragm. In general it enables a vat of larger diameter, and consequently of less capital cost per ton treated, to be used than is otherwise possible.

The accumulated slime, after aeration treatment, is pumped to current slime plant for cyanide treatment. The following average figures from a three month's run show such highly satisfactory results as to warrant more attention being paid to this method of treating accumulated slime:

Value of charge	2.460 dwt.
Value of residue	0.278 dwt.
Extraction	77.7%
Lime consumed per ton (50% CaO)	18.079 lb.
Potassium cyanide per ton	0.233 lb.
Lead acetate per ton	0.121 lb.

The total working cost in connection with the treatment of this slime is 3s. 8.1d., which includes 1s. 5.3d. for collecting and pulping.

The Brown vat is also successfully used for the treatment of sand. At the plant of the Simmer & Jack Proprietary Mines, Ltd., an air-lift vat, 13 ft. diam. and 18 ft. deep, with a central pipe 16 ft. 6 in. long and 10 in. diam., is used for treating 12-ton charges of black sand. The black sand is previously finely ground in a small tube-mill. After the pulp of sand and water is in circulation, lime is added, and later on lead acetate also. Agitation is continued until all soluble sulphides are decomposed, a period of about 16 hours. Cyanide solution is then introduced under pressure into the bottom of the charge, and the solution of the gold commenced, periods of agitation, settlement, and decantation following one another alternately until the value of the decanted solution indicates complete treatment. After each decantation, a centrifugal pump, connected with the bottom of the vat, and discharging externally into the top of the vat, is used to withdraw any sand which may have settled at the bottom of the cone below the air-lift and put into general circulation again. The head samples assay about 10 oz. gold per ton, and over 97% extraction is obtained with a cyanide consumption of only 2 lb. per ton.

The air-lift has been in use for the elevation of various liquid materials since 1892; in Western Australia it was used for pumping battery tailing in 1902; and though F. C. Brown, as mentioned before, introduced the central air-lift tube into his tall agitators in 1904, A. F. Crosse actually used the air-lift on the Rand for the experimental agitation of slime in 1903. Mr. Crosse's method of decanting an overflow from an agitation-vat seems to have been useful to inventors. In the Paterson vat this principle is made use of as well as that of the Brown vat, decanted solution, free from sand, being passed outside the vat and drawn through a centrifugal pump. This delivers the pulp again to the bottom of the lift-pipe, taking the place of the air of the Brown vat. The makers give 4½ hp. as the probable power required to agitate 50 tons of (dry) slime in a 15 by 45-ft. vat. By way of comparison it may be noted that in a Brown vat of the same size at the Hacienda San Francisco, at Pachuca, 112 short tons of (dry) 'slime' are agitated with about 2 hp. Vertical circulation pipes in a Brown vat, with their upper orifices, which are protected by goosenecks, just below the surface of the pulp and lower orifices near the mouth of the air-lift were suggested by W. M. Brodie. Their use was mainly the prevention of choking by heavy sand around the opening of the air-lift.

Well-Drilling Methods

The history of well drilling from its earliest practice in China down to date is traced by Isaiah Bowman in a recently issued Water Supply Paper, No. 257, of the U. S. Geological Survey. The report also contains descriptions of the many methods of drilling now in use in the United States, including not ony drilling for water but for oil and other resources. The credit of reducing well drilling to a science belongs to the Chinese, but in this, as in many other things, the Chinese engineers have made but slight improvement during the last century, which has witnessed so remarkable an advance in mechanical development in the United States. Mr. Bowman regards the use of well casing as the greatest improvement yet devised for oil drilling and notes that holes can now be sunk safely and rapidly to a depth of 5000 ft. He describes the various tools and rigs required for different kinds of drilling, ranging from those used in the shallow hand-driven well of perhaps 20 ft. to those used in drilling wells of maximum depth.

Gold Nuggets of California

By Alexander Del Mar

Below is given a list of the gold nuggets known to have been found in California. Of necessity, the list is inaccurate and incomplete, and it would be of historical interest if those who know of other finds of nuggets, say of 30 ounces or over, would put on record the date, locality, name, weight, and value.

Year. Locality and Finder.	Oz.	Value.
1848—January 18. Date of the most celebrated discovery of gold in California. Scene, the American river near Colima, Eldorado county. From this place Tom Marshall brought into Sutter's Fort, near Sacramento, a small sackful of nuggets, the first one of which had been picked up by his little daughter. This nugget is preserved by the Pioneers' Society of San Francisco. Marshall's sack contained approximately	50	$ 1,000
1848—Wood creek, SW. of Sonora, Tuolumne county	900	15,000
1848—Knapp's ranch, E. of Columbia, Tuolumne county; Mr. Strain	396	8,500
1849—Illinois canyon, near Georgetown, Eldorado county	50	1,000
1849—Sullivan's creek, Tuolumne county, weighed 28 lb	408	7,168
1849—Gold Hill, near Columbia, Tuolumne county; Mr. Virgin	380	6,500
1849—Spring Gulch, near Columbia; a Frenchman	250	5,000
1850—French Ravine, Sierra county, three nuggets	935	18,000
1850—Quartz nuggets, Tuolumne county (a pocket of $360,000)	1500	28,000
1850—French Ravine, Sierra county, one quartz nugget	263	4,890
1850—Georgia Slide, Hudson gulch, Eldorado county	50	1,000
1850—Oregon canyon, Eldorado county, Fay nugget	62	1,250
1850—Kelsey, Eldorado county	195	4,700
1850—Holden's Garden, Sonora, Tuolumne county	1500	30,000
1851—Camp Corona, Grizzly mountains; Oliver Martin	1818	22,750
1851—Morgan mine, Carson Hill, Calaveras county (pocket of $3,000,000)	350	6,500
1851—French Ravine, Sierra county	426	8,000
1853—Columbia placers, Eldorado county, six nuggets	1755	35,000
1853—Same place, one nugget	105	1,800
1853—Columbus, Tuolumne county, 283 oz., clean	360	5,265
1854—Carson hill, Calaveras county, several nuggets, one of	2340	37,400
1854—Nevada county, nugget	780	17,500
1854—Camp Seco, Stone Cabin gulch; Frank Russworm	93	1,760
1854—Live Yankee, Forest City, Sierra county, from 1854 to 1862 yielded 12 nuggets, 30 to 170 oz	1000	20,000
1854—Spanish Dry Diggings, Grit seam; Texas & Jacobs	60	1,000
1855—French Ravine, Sierra county	532	10,000
1855—Remington hill, Nevada county	186	3,500
1857—Manhattan creek, Georgetown, Eldorado county	62	1,200
1857—Garden Valley, Eldorado county; Samuel Treeworgee	28	525
1859—Magalia, Butte county; Ira A. Willard.	533	10,690
1859—Butcher Ranch, Auburn, Placer county, twin nuggets	240	3,264
1860—Same place, same finder (Ed. Gilbert).	147	2,852
1860—French Ravine, Sierra county	93	1,755
1860—Monumental Quartz, Sierra Buttes; W. A. Farrish. This nugget sold for $23,637, more than its value as gold.	1596	17,655
1860—Sierra county, nugget, probably same as last	1146	20,000
1860—Spanish Dry Diggings, Pennsylvania seam	36	500
1861—Smith's Flat, Sierra county	80	1,505
1861—Oregon claim, Forest City, 12 nuggets, 30 to 100 oz	750	15,000
1862—West branch, Feather river near Magalia; Morrison	80	1,605
1864—Michigan Bluff, Placer county	226	4,205
1864—Smith's Flat, Sierra county	140	2,605
1865—West branch, Feather river near Magalia	90	1,760
1865—Lowell hill, Nevada county	58	1,100
1865—Spanish Dry Diggings, Dendritic gold, Fricot's specimen	101	3,500
1866—Smith's Flat, Sierra county	146	2,715
1867—Remington hill, Nevada county	128	2,460
1867—Gibsonville, Sierra county; G. H. Norman and Frank Aman	100	1,700
1867—Pilot hill, Eldorado county, Bowlder Gravel Claim	426	8,000
1869—Little Grizzly, Sierra county	107	2,000
1869—Hope claim, Sierra county	94	1,770
1870—Little Mule creek, Trinity county, two nuggets	277	4,700
1870—Spring creek, near Redding, Shasta county	185	3,200
1870—Same place; Oliver Longchamp and Fred Rochon	310	6,200
1870—Rainbow mine, Alleghany, Sierra county	1200	23,000
1873—Buckeye mountain, Trinity county, two nuggets	190	3,500
1876—Polar Star mine, Dutch Flat, quartz; J. B. Colgrove	285	5,760
1877—Mohave desert, San Bernardino county, 'Delmar's Luck' nugget	108	2,000
1880—Groot's Ferry, Siskiyou county	110	2,000
1880—Flat creek, near Redding, Shasta county; Dent Young	30	520
1882—Holloway hydraulic 'Christmas Pudding' nuggets	100	2,000
1891—Goler district, Mohave desert, two nuggets, $2120, $975	156	3,095
1894—Canyon, San Jacinto mountain, San Bernardino county; Jerseyman	70	1,400
No date—Nelson Creek, 140 oz.; Elizabethtown, 134 oz.; Mohawk Valley, Plumas county, Hays & Stedman, 420 oz.; Minnesota, Sierra county 206 oz.; together	960	18,000

Gold Fields American Development Co., Ltd.

It is announced by the management of the Consolidated Gold Fields of South Africa, Ltd., that it is proposed to register an American company with a capital of £2,500,000 in a like number of shares of £1 each. In exchange for its interests in Natomas Con., Oroville Dredging, Ltd., Yuba Con. Gold Fields, and the Sierra Pacific Electric Co., 1,000,000 of these shares will be issued as fully paid to the old company, and in order to provide additional capital for the extension of business it is proposed that a further 1,000,000 shares of the new company shall be subscribed for by the old "company at par, the balance that 500,000 shares remaining in reserve. In addition to the skilled attention given by H. H. Webb and Baron von der Ropp to opportunities for investment in America, an arrangement has been made with John Hays Hammond, who was for many years consulting engineer to this company, by which he undertakes to give to the new company the best of his experience and advice, the advantage of preferential rights over new business which may reach him

through his wide and influential connections in America, and also his assistance on the committee which it is proposed to establish in New York, on which it is intended to also secure the presence of other gentlemen of eminent financial position."

One of the first steps taken by the new company will be the extensive exploration of valuable placer ground on the west coast of Colombia.

West Australian Gold Production

The value of the gold production of Western Australia for February 1911, was $1,818,000. The individual production of the leading mines is given below:

Name.	Tonnage.	Value.	Profit.
Associated	1,099	.....	.....
*Associated Northern Blocks..	1,439	$14,500	.....
†Bullfinch Proprietary.....	237	46,000	.....
Burbank's Main Lode.....	1,576	22,500	.....
Chaffers	3,360	23,000	$650
Golden Horse-Shoe	25,071	165,000	11,500
Golden Ridge	2,473	31,000	15,000
Great Boulder Perseverance..	18,205	119,000	22,000
Great Boulder Proprietary...	16,218	215,000	116,000
Great Fingall	9,534	71,000	12,000
Hainault	4,367	31,500	3,600
Ivanhoe	18,229	195,000	90,000
Kalgurli	10,040	116,000	57,500
‡Lake View Consols.....	8,740	8,400	2,500
Lake View & Star.....	12,035	75,000	2,000
‡Oroya Exploration	19,295	15,000	3,500
Oroya Black Range	4,210	42,000	10,500
Oroya Links	6,798	41,000	950
Sons of Gwalia.....	13,498	118,000	46,000
Sons of Gwalia South.....	2,202	18,500	5,600
South Kalgurli	9,013	59,000	12,200

*No clean-up, as new mill had just run for a week.

†Profits not published.

‡Residue treatment.

The production of gold since 1886 has amounted to 714 tons.

	Fine oz.	
1886	270	£1,148
1896	251,619	1,068,808
1903	2,064,801	8,770,719
1908	1,647,911	6,999,882
1909	1,595,269	6,776,274
1910	1,470,632	6,246,848

The value of the gold produced per man employed was £413 in 1910. For every 100 oz. of gold produced in Australia in 1910 the respective contribution was:

Western Australia	46
Victoria	19
Queensland	13
New Zealand	14
New South Wales	6
Tasmania, South Australia, Northern Territory, and Papua	2

The following table shows the total value of the mineral production of Western Australia to January 31, 1911:

Gold (to 28/2/11)	£98,989,676
Copper	979,357
Tin	926,808
Coal	829,735
Lead	364,756
Silver	247,147
Ironstone	36,695
Limestone	18,290
Tantalite	13,486
Pig lead	13,306
Silver-lead ore	10,863
Asbestos	1,754
Wolfram	546
Sundry minerals	12,832
	£102,445,251

Resignation of Dr. R. W. Raymond

The special committee appointed by the Council of the American Institute of Mining Engineers to consider the resignation of Dr. Raymond has issued the following statement:

At the meeting of the Board of Directors, and of the Council of the American Institute of Mining Engineers, February 21, 1911, Dr. R. W. Raymond asked for the appointment of a joint committee to receive and consider a communication (which was duly sent by him under date of March 16) tendering his resignation as member and secretary of each body. On March 31, the Board of Directors and the Council accepted the resignation of Dr. Raymond, and on the recommendation of the Council, the Board authorized and directed his appointment as Secretary Emeritus, upon whom the Council may call for special editorial and other services in connection with the publications of the Institute. Dr. Raymond's desire is thus met, since he will be entirely relieved of the executive and administrative duties at a time when they will be greatly increased by many suggested extensions of the activities of the Institute. At the same time, the Council retains his active co-operation in much of the special work for which he is so exceptionally qualified by training and experience, and also secures his valuable advice based upon his intimate knowledge of the history of the Institute, and his wide acquaintance with the membership at home and abroad.

Dr. Raymond was one of the founders of the Institute in 1871; he was elected first vice-president, and became president the same year. He was annually re-elected in 1872, 1873, and 1874, and was formally and informally connected with the management until 1883, when he was appointed secretary to succeed Dr. Thomas M. Drown. Dr. Raymond was elected secretary in February 1884, and since then he has been annually re-elected by unanimous vote. Our *Transactions* bear eloquent testimony, in the accuracy of technical statement and literary finish, to Dr. Raymond's wide expert knowledge and editorial genius. He has enriched the literature of the profession by his translation, in 1893, of Posepny's great treatise on Ore Deposits, and he has contributed to our *Transactions* very valuable original papers on Mining Law, the Divining-Rod, Ore Deposits, etc. Through his knowledge of foreign languages, and his acquaintance with foreign experts and American engineers, he has done a great deal in building up the Institute, and securing for it an international as well as a national standing. Dr. Raymond has given to the Institute his entire professional library; he has sacrificed private practice, and he has contributed from his private means, to its success.

At the same meeting the Board of Directors elected Dr. Joseph Struthers a member of the board, secretary to the board, and a member of the Library Committee to fill the vacancies created by the resignation of Dr. Raymond. The Council appointed Dr. Joseph Struthers secretary of the Council for the unexpired term, and member of the Committee on Membership, his duties to include also those of editor and assistant treasurer. Dr. Struthers began his service with the Institute in 1903 by appointment as assistant editor. In February 1906 he was appointed assistant secretary and editor, and a few months later there were added to his duties those of assistant treasurer, so that he has had years of experience in all branches of the work of the Institute. Dr. Struthers has been identified in recent years with the management of the building of the United Engineering Society, as chairman of the House Committee, secretary of the Library Conference Committee, and since 1910 as trustee and treasurer of the United Engineering Society.

Prior to Dr. Struthers' connection with the Institute, he was, for fifteen years, a member of the teaching staff of the department of metallurgy, School of Mines, Columbia University, and later, for four years, was editor of 'Mineral Industry.' Dr. Struthers, therefore, through his long service with the Institute, and through his work in cognate lines, brings to it the necessary equipment in training and experience, for his duties as secretary.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Weight and Volume of Ore

The Editor:

Sir—In your issues of April 1 and 22, A. E. Robinson and A. L. Gerry comment on my article on 'Weight and Volume of Ore.' I would again warn the writers of the fact that ores are more or less porous, even when 'compact,' and that large pieces may contain cavities. The object of using wheat was that such cavities or pores should not be filled. I might add that in the test referred to, to prevent entrance of water, individual sample pieces were paraffined.

L. S. AUSTIN.

Salt Lake, Utah, April 26.

Tank Versus Vat

The Editor:

Sir—KCN's remarks upon 'Tank Versus Vat' recalls that in *Hampton's Magazine*, illustrating Eugene P. Lyle's article on the 'Smelter Trust,' was a picture of a copper matte smelting furnace, the descriptive note below the picture stating that the 'copper' passed through the large 'vat' in front of the furnace. Now is a furnace fore-hearth not also a vat? I vote with KCN on that, as also on his feeling that the present generation of metallurgists, at least, will balk at the term 'smeltery,' even if the lexicographer does sustain the Editor of *The Engineering and Mining Journal*. Somehow I always felt that if the 'Trust' had brought suit against *Hampton's Magazine*, that use of the word vat would in itself almost have proved the contention of the prosecution, that the writer was not sufficiently informed on his subject.

El Paso, Texas, April 5.

Arizona Copper Belt M. Company

The Editor:

Sir—I note in your issue of April 8 a letter from R. W. Groo, Bingham Canyon, Utah. In regard to the letter to which Mr. Groo refers, I wish to say that through an error by the printer this was inserted, but that as soon as the mistake was discovered the prospectus was corrected. Apologies and explanation were tendered Mr. Groo by myself, and I wish to again apologize through the medium of your paper. The error was not intentional, and I am doing all in my power to right whatever wrong was done. I wish to exonerate the Arizona Copper Belt Mining Co. in regard to this letter, as its officers knew absolutely nothing about it until a short time ago. They have invited Mr. Groo to examine the property, and feel sure that upon examination he will feel satisfied that his reputation is in no wise jeopardized.

The explanation of printing the letter is this: I had written Mr. Groo, who was an old friend, to write a letter for me, enclosing with my request a draft of what I wished him to say. This, however, contained nothing in regard to his having examined the mines. A copy of this as I would have had it reproduced was given the printer, who took the liberty of making additions. I let the matter go, not having heard from Mr. Groo (subsequently my letters were returned), and when the booklets came from the printer the letter was included. As I said before, the error was corrected as soon as possible and no stock was sold through the mails by their use. I would further say that the mines of the Arizona Copper Belt Mining Co. are not of a 'wild-cat' nature and they are being financed only among friends of the officers. I trust that as a result of the explanation tendered Mr. Groo personally as well as this one, Mr. Groo will be convinced that no intentional misuse of his name was intended. I will deem it a favor if you will publish this in answer to Mr. Groo, and thank you in advance for assisting me to right an unintentional wrong.

F. A. CRAMPTON.
(General Manager.)

New York, April 19.

Positions Wanted

The Editor:

Sir—In a recent issue of *The Engineering and Mining Journal* a letter, by Mark R. Lamb, on the difficulty of securing employment by members of the mining engineering profession, has caused considerable comment. This discussion is well timed and would result in much good to many members of the profession, if it should prove possible to put into practice any plan which would obviate the difficulties and expense of each man getting the place he is best fitted for and the corporation getting just the man needed for each place. There are many who, without doubt, have had the experience of not being able to find the right job when wanted. Aside from the men who are unavoidably out of employment and those who are just making a start in life and trying to get a foothold, there are those who, although they are 'holding down their jobs,' are unsuited for them in many ways and who, if they could get the right employment could make a change to the advantage of all concerned. In still other cases there are many who are capable of doing more than they have the opportunity for, in the present location, and are looking for new fields to conquer. For these, there is special injustice, as a change in many cases, is almost impossible to make.

I should be glad to hear from those interested, as it has been suggested to me by Mr. Lamb, that, as he will necessarily be absent in South America for some time, I should continue the work started by him until, as proposed by Mr. Herty, this important matter can be taken up by some such organization as the American Institute of Mining Engineers. In the meantime I shall be glad to offer the use of my letter-files to those looking for men, as well as for those seeking employment.

RAYMOND C. BENNER.

University of Arizona, Tucson, April 17.

A B C of Empire Drilling

The Editor:

Sir—I note in your issue of April 1 a letter from R. B. McGinnis, as also a letter from Fred J. Siegel in your issue of February 25, both in relation to the Empire hand-drill, which is manufactured by the New York Engineering Co. The point in question between these two gentlemen is the matter of keeping the casing plumb when drilling in loosely packed gravel as described by Mr. McGinnis. There is a centering device made by the company which keeps the casing plumb during all drilling operations. This should be used when drilling in loosely packed gravel containing large boulders. I believe the Empire drill outfit contains a tool for any and every condition that will be encountered in any placer drilling in the world. I also note Mr. Siegel's criticism on the hardness of the cutting shoes. These cutting shoes are made of nickel steel, quite highly tempered when they leave the works, and they are suitable for drilling in medium gravel. In case the drill encounters large boulders and it is necessary to drive the casing, then the temper should be drawn slightly. This is easily done, and after two or three holes have been drilled, the driver soon learns something of the nature of the deposit, and the temper of the shoe should be regulated accordingly. This shoe does an immense amount of cutting, as it is being constantly rotated during all drilling operations, and, therefore, if it can be used in its hardened condition, it will last much longer than otherwise. It is important that the teeth of the cutting shoe be kept fairly sharp and square, as they will then cut a core of the exact diameter of the outside of the cutting shoe. This enables the engineer to calculate the value of the ground contained in the drill-hole with

great accuracy. This is one of the principal reasons for the great popularity of the Empire drill, and it is important that all operators should appreciate the fact that the cutting shoe should be used as hard as possible. Then the teeth will keep sharp and square and will cut a core that will coincide with the theoretical core. This is most important, as all drilling results are usually figured on the assumption that a core of a certain diameter is obtained, and the nearer this is approached in actual work, the nearer the results will coincide.

A. C. LUDLUM.

New York, April 14.

Mining Method Wanted

The Editor:

Sir—The following are the conditions for which a safe and inexpensive method of mining is sought: An irregular body of ore standing at an inclination approximately 55°, 10 to 50 ft. wide, 175 ft. long on the strike, 140 ft. high, and surrounded by a zone 30 to 60 ft. wide, of friable, shelly limestone which caves in large masses on being slightly disturbed. The ore is but little more firm than the surrounding barren shattered limestone. The high cost of timber at this mine practically prohibits its extended use.

MINER.

Casa Grande, Arizona, March 17.

[The conditions here described certainly present difficulties, whatever the method adopted, and particularly to any without the use of timber. In proposing a method for the safe and cheap extraction of such a mass of ore as that described, such proposal can only be considered in the way of a suggestion, as the method may have to be modified in several particulars as work proceeds, or it may have to be abandoned altogether for some other method better suited to existing conditions. It is not stated, and it is probably unknown, how large a superficial area may be removed without affording support to the back. Much depends upon this, for if only a small area can be mined without timber, or support of some kind, it will be found most difficult to recover all, or nearly all of the ore from this mass. The most feasible method that suggests itself, in view of the limited information given, is top-slicing as practised at Cananea, Mexico, and in the Clifton-Morenci district, Arizona. To adopt this method, a level should be started by running a drift along the foot-wall of the orebody, about 100 ft. below its top, and from this driving a series of cross-cuts to the hanging-wall side of the deposit. These cross-cuts should be 30 ft. apart, centre to centre. Raises should then be run up from the cross-cuts to within 15 or 20 ft. of the top of the orebody. The centres of these raises should not be over 30 ft. apart, and they should each be divided into two compartments, one for ore, the other for manway and ventilation. When the raises have been finished a stope should be started at the top of them, the ground being supported by square sets. This stope should be carried up three sets high, the ore being sent down through the raises. The width of this stope may be anywhere from 30 to 60 ft., depending on the way the ground stands. This is the only level in which square sets need be employed. Probably in this case the square-set stope should not be cut wider than 30 ft., that is, 15 ft. on each side of the line of raises from one of the cross-cuts below, preferably that nearest one end of the orebody. When the ore has been mined three sets high and over a good sized area, a floor should be laid on the sills of the lowest sets. These sills at Cananea are of 5 by 10-in. timbers each 10 ft. long, being the length of two sets. The sills are laid from foot to hanging, that is, across the strike of the vein. The floor consists of 2-in. plank and any old timber available. It may be possible to remove a portion of the square-set timbers. If they can not be taken down without danger to the men, they must be started caving by blasting some of them on the hanging-wall side, so that the hanging-wall country will cave, covering the floor of the stope. The first slice beneath this floor is then started on the hanging-wall side, and if possible at one end of the orebody. The slice should be 10 or 11 ft. high and carried as wide as the square-set stope above it. A drift is run some distance in advance of each slice heading, extending as far at least as the next raise. Mining proceeds backward toward the foot-wall, the sills of the square sets overhead being temporarily propped up by means of caps and stulls, or by stulls alone, which holds the floor and its burden of waste until the miners can blast out a few feet of the ore of the slice and send it down to the chutes in the main level below, through the raises cut for this purpose. As the face of the slice advances the stulls are pulled or shot down by the miners. At least one raise must always be accessible to the men working on a slice. When the slice is well advanced, work may be commenced on the second slice immediately beneath the first, in the same manner as the first. Stoping may also be continued on the next block of square sets, so that when a slice is completed another may be cut at its side in the same manner as before. In this manner the work proceeds the entire length of the orebody and from level to level. It requires considerable foresight and much preliminary arrangement, but the system is a good one, involving little risk—not more than by other methods, and in the end is less expensive than by the all square-set method. The waste rock that first falls on the floor of the square-set stope follows the miners down as slice after slice is removed, additional waste falling on top of that which first caved, the entire mass settling as work underneath it proceeds. This method of mining was described in considerable detail in the *Mining and Scientific Press*, December 24, 1910, pages 834-835.—EDITOR.]

Recording Mining Locations

The Editor:

Sir—I note with pleasure in the discussion concerning the re-location of mining claims in the *Mining and Scientific Press* for April 22, E. L. Ballou calls attention to the desirability of recording notices of claim locations with the Land Office. In *The Engineering and Mining Journal* for April 27, 1905, I suggested such a change in recording notices of location, recommending that the description include, when the claim lies within the surveyed lands, a statement of the township, range, and section in which it is located; and also suggested that after such a notice is recorded at the Land Office, these sections should not be sold as timber lands, agricultural land, or for any other purpose without notification to the claimant of the mineral location. This proposed amendment to section 2324 of the Revised Statutes also included a recommendation that an affidavit, declaring the annual work to have been done, and all monuments to be in proper condition, should be filed with the Land Office by the first of January, and that failure to file such affidavit should be deemed a notice that the claim is abandoned. This latter provision would be the compelling clause which would require the claim holders to record their proof of labor covering a question raised by Mr. Ballou. No man would wish to lose his claim, and would be just as careful to record proof of annual labor as to record the original notice of location.

Since the above recommendation was made several instances have come to my knowledge of land being taken up as a homestead or as timber land, upon which mineral locations had been made. In one of these instances, I was told that several thousand dollars had been spent on the mineral location, but title passed to the timber claimant, because the owner of the mining location was not aware that the property was being sold as timber land until after the sale was completed. In order to have these notices of location of mining claims placed on file at the Land Office, legislation must be enacted requiring the registrar of the Land Office to receive these notices when sent to him, otherwise the simple sending of a duplicate notice of location, as suggested by Mr. Ballou, will be of no value, and the notices will receive no attention at the Land Office. The question asked of the Commissioner of the Land Office at Washington as to whether there would be any difficulty in having these notices filed at the local Land Office, and the claims entered on the tract book, brought forth the reply that there was no legal provision for doing this at present. It

seems highly desirable that an effort should be made to have legal provision enacted so that the locator of a mining claim may be protected. I note, in going about the country, that there appear to be fewer and fewer prospectors in the mountains every year. Where there are no prospectors very few new mines are found, and the maintenance of the mining industry requires that everything possible should be done to encourage the prospector.

GEO. A. PACKARD.

Butte, Montana, April 27.

A Case for the Stamp-Mill

The Editor:

Sir—The poor old five-stamp battery appears to be getting some hard knocks in the technical journals, as is the case every year when milling progress is reviewed, but in spite of all the other machines tried, it has always 'come back.' I am somewhat partial to my old friend, and I maintain that these criticisms are not justified. The one-stamp advocates declare that in consequence of the large screen-area five individual stamps will crush more ore than one five-stamp battery. Perhaps this is true, as stamps are ordinarily worked, but will five ones with quadruple discharge do more work than one five with a quadruple discharge? I believe not, for the screen area in the single-unit battery is far in excess of the crushing capacity. Close up one side of a single quadruple-discharge mortar, and the capacity for crushing remains the same. Make a quadruple-discharge or a double-discharge five-unit mortar with as little space as possible in the mortar not occupied by crushing surfaces, and I am willing to argue that this battery will not only crush ore as fast as single stamps and break as many screens as the one, but will last as long and be more easily worked. One big feeder is preferable to five small ones; one belt is better than two, and two cam-boxes are easier to grease than four.

Making a special plea for the California ores where amalgamating is of prime importance, the single unit loses outright. Other machines requiring previous drying, such as rolls, or those machines requiring preliminary crushing to about ½-in. mesh, such as Chilean and roller mills, have not made a sufficiently strong case for a verdict in their favor.

The small mine-owner pays for mining experiments. The big mine-owner can afford intelligent advice, but the small man, unheedful of the risk he takes, is willing uncomprehendingly to make the experiment of a new machine which the sellers themselves may have never tried except on paper. The amount of power required in a stamp-mill is easily determined by ordinary arithmetic; not so that for other machines. This leads sellers to underestimate the power required in their 'best sellers.' Here the small mine-owner often gets fooled. He is looking for low power-consumption. He may get it along with small crushing capacity. I do not mean to argue that falling stamp utilizes the full power of its fall in effective crushing. It does much less than this, as do all other crushing machines, some more, some less, according to the physical character of the ore. If it were possible economically to dry ores, crush them with rolls, amalgamate thoroughly in mixers and on plates, it might be feasible to use rolls, but the cost of drying the ore is sufficient argument against this system.

I have heard it remarked that South African engineers do not give sufficient attention to the possibilities of the single-stamp mills. Perhaps the answer is that it is too simple for their conditions. They have done much experimenting, and this subject cannot be new to them. Two men can run 20 five-stamp batteries for at least two shifts without any extra help, but heaven help the two men who try to manage 100 one-stamp batteries. If the ore happens to be a bit sticky, half the stamps would be up, for one man could hardly keep 50 screens repaired or keep 50 small feeders working. In a previous paper, last year, I made out a good case for the single-stamp battery, but I was then only considering it as compared with the ordinary single-discharge five-stamp battery.

Los Angeles, April 8. ALGERNON DEL MAR.

Phosphate Discoveries

The Editor:

Sir—In the *Mining and Scientific Press* of February 11, I notice that Charles Colcock Jones makes a protest concerning the lack of recognition of his pioneer work on the phosphate deposits of Utah, Idaho, and Wyoming. I note your apology to Mr. Jones for having previously neglected to credit him with the discoveries. Nevertheless I take pleasure in adding my note of confirmation to Mr. Jones' statements. During the months of September, October, and November 1906, I made, for private clients, an extensive examination of these phosphate deposits, the true nature of which had been first recognized by Mr. Jones, and the most important of which had been located by him in the previous three years. Mr. Jones was in the field at the time, and rendered me the greatest assistance. A careful search through all the geological literature which I made failed to reveal the fact that any one previously to Mr. Jones' discoveries had recognized the value of the deposits, or indeed that phosphate rock existed in the region. I do not know how much of an economic asset the deposits are at present, as I have not recently followed the developments. But I can testify that all the credit of the first discovery of this extensive field of phosphate-bearing rocks is due to Mr. Jones, and to him only. He would be the first to admit that he used as a guide in his work the structural maps of the Hayden Survey, tracing the geological horizon thereby. But neither in the Hayden reports nor any subsequent reports of the U. S. Geological Survey, previous to Mr. Jones' recognition of the phosphate, was any reference ever made to phosphate rock in the region, so far as I am aware. The work of the geologist, whether he be publicly or privately employed is equally valuable, and the failure to recognize fully the importance of the contribution which Mr. Jones has made to economic geology, and to credit the discovery to its proper source, would be to perpetuate a glaring injustice.

C. W. PURINGTON.

London, April 14.

[We are glad to publish this tribute of one engineer to another. It breathes a spirit we like to see animating the profession. Incidentally it affords opportunity to call attention to pioneer work by another engineer, Lewis T. Wright, to whom the mining industry is indebted for more than one valuable discovery. When trouble over smelter fumes became imminent, Mr. Wright took up the whole matter of disposal of smelter fumes and reached the conclusion that manufacture of acid and fertilizer afforded the most satisfactory solution of the difficulties. At that time the presence of phosphate rock in the West was unrecognized. Mr. Wright, acting for his company, placed advertisements in many country papers offering to test free any material suspected to be phosphate rock. Much worthless material was sent in, but among other specimens were some that showed the presence of phosphate. Mr. Jones, then employed by the Mountain Copper Co. Ltd., was thereupon sent into the field to study the occurrence of the rocks and, first for the company, and later for himself, located and acquired claims. The attention thus attracted to the deposits has already resulted in establishment of important industries, and there can be no doubt that even larger developments will be made.—EDITOR.]

THE APOROMA PLACERS, now being worked by an English company, are in the province of Sandia, Department of Puno, Peru, at an elevation of 7000 ft. The first year's work on the gravel, which averages 21c. per cubic yard, is expected to yield $250,000 in net profits. The estimated amount of gold-bearing gravel at present available for washing, calculating an average depth of 48 ft., is 49,000,000 cu. yd., giving a net profit of $9,000,000. The old ditches and reservoirs, which were constructed by the Incas and Spaniards, have been cleaned out and surveyed. The ditches which were built in smooth slate rock, will be used after straightening and widening in places. It is expected that hydraulic operations will begin by October next.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TURQUOISE DEPOSITS have been worked in Arizona, California, Colorado, Nevada, New Mexico, and Texas. Turquoise is generally found in arid or desert regions, where mining is difficult. New Mexico, California, and Arizona were formerly the chief sources of turquoise, but during the last few years Nevada has been one of the principal producers.

LITHIUM (the metal) has no known practical use. It oxidizes very readily, is soft, not very tenacious, and is not known to have other properties that might make it economically valuable. Of the lithium salts, lithium bromide is used in photography and in medicine, and various other salts are used for lithiasis (gravel), arithritis (inflammation of the joints), chronic rheumatism, and gout.

SAMPLE CRUSHERS that are effective and also particularly useful where specimen ore makes 'mortaring' at times advisable, are easily rigged wherever compressed air is available. All that is necessary is an old drill and a suitable mortar. Such a crusher, seen at the Harvard mine, near Jamestown, California, consists of an air-drill mounted on a post as when such drills are converted into steam-hammers, with a pestle in place of ordinary drill steel, and a mortar set on a block below.

THE FIRST STEEL produced in this country was probably made in Connecticut in 1728 by Samuel Higley and Joseph Dewey. Crucible steel was first successfully produced in the United States in 1832 at the works of William and John H. Garrard, at Cincinnati, Ohio. Bessemer steel was first made in this country in September 1864, by William F. Durfee at an experimental plant at Wyandotte, Michigan, and open-hearth steel in 1864, by the New Jersey Steel & Iron Co., at Trenton, New Jersey.

CRUSHED-STEEL ABRASIVES are manufactured from steel which is heated to nearly white heat and quenched in a bath of cold water. The fragments of steel thus produced are crushed to particles varying from fine powder up to pieces one-sixth of an inch or more in diameter. The crushed product is then classified and tempered, and is known as 'diamond crushed-steel,' 'diamond steel-emery,' and 'steelite.' Crushed steel is used chiefly in the stone, brick, glass, and metal trades, the size of the steel used depending on the character of the stone to be cut, rubbed, ground, or polished.

CHROME ORE is used extensively in the manufacture of ferrochromium, employed for making special steels, alone or in combination with tungsten, manganese, nickel or other steel-hardening metals. It is also used for lining copper, lead, steel, and other furnaces where the corrosive action is very great. For this purpose it is used either in the crude form or as chrome brick. A third use of chromite is in the manufacture of various chromium compounds, such as oxides and metal chromates for use as pigments and as dyes, and alkaline bichromates for use as mordants and as tannages.

WOOD PRESERVATION through chemical treatment has come to be considered perhaps the most important phase of forest conservation, next to checking the waste from forest fires. To lengthen the life of wood will lessen the drain on the forests, and consequently postpone the exhaustion of the country's timber supply. Not only does the preservative treatment of the timber bring about a direct saving to the individual timber user, but the general adoption of such measures means a great saving to the timber sources of the nation as a whole. At the present rate of consumption, the exhaustion of the supply of the better class of structural timbers in the United States is a thing of the near future.

EXTRA LONG cages for handling timbers are used at the Kennedy mine, in California. They are hung, when needed, below the regular skip, being attached by cable and hook. When not in use the cages are swung out over the platform at the collar of the shaft, attached to an overhead trolley, and run to one side just as material is handled in a shop by means of an overhead crane. They are thus immediately available, are easily attached, and are swung into place and out again with little labor. The guide shoes on these cages instead of being fixed, have one side hinged. It is turned into position after the cage is between the guides, securely locked by means of a pin, and the cage is ready.

SCRAP MICA, or mica too small to cut into sheets, and the waste from the manufacture of sheet mica, are used in large quantities commercially. The greater part is ground for the manufacture of wall-papers, lubricants, fancy paints, and molded mica for electrical insulation. Ground mica applied to wall-papers gives them a silvery lustre. When mixed with grease or oils mica forms an excellent lubricant for axles and bearings. Mixed with shellac or special compositions, ground mica is molded into desired forms and is used in insulators. Ground mica so used should be free from metallic minerals. Mica used for lubrication should be free from gritty matter; for this use only pure mica should be ground, or the grit should be eliminated after grinding. For wall-papers and brocade paints a ground mica with a high lustre is required, and such lustre is best obtained by using a clean light-colored mica and grinding it under water.

IGNEOUS ROCKS, as that term is used by the United States Geological Survey, are those that have cooled and consolidated from a state of fusion. Molten material or magma from the bowels of the earth has from time to time been forced upward in fissures or channels of various shapes and sizes through rocks of all ages to or nearly to the surface. Rocks formed by the consolidation of molten material, cool slowly, with the result that intrusive rocks are generally of crystalline texture. Where the channels reach the surface the molten material poured out through them is called lava, and lavas often build up volcanic mountains. Igneous rocks that have solidified at the surface are called extrusive or effusive. Lavas generally cool more rapidly than intrusive rocks, and as a rule contain, especially in their superficial parts, more or less volcanic glass, produced by rapid chilling. The outer parts of lava flows also are usually porous, owing to the expansion of the gases, originally present in the magma. Explosive action, due to these gases, often accompanies volcanic eruptions, causing ejections of dust, ash, lapilli, and larger fragments. These materials, when consolidated, constitute breccias, agglomerates, and tuffs.

UNLOADING TIMBERS from deep skips is usually a long and tedious job. At the Argonaut mine near Jackson, California, the men have a method that is both simple and expeditious. The skip having been lowered until its edge is flush with the station platform, light timbers are lifted out by driving into them with a timberman's axe, one man at the top of the timber is to lift it and a second at the lower end to swing it out. In the case of heavy timbers, and in this mine posts 30 inches in diameter are used, a rope is looped loosely around the upper end of the stick. The rope runs over a pulley fastened in the roof timbers of the station, and down to a 'snubbing-pin' at the side. It being ready the timberman signals the engineer to hoist and the skip is lifted until its bottom is clear of the station platform and stopped there, the assistant meanwhile taking up the slack in the rope. The skip is then lowered and as the bottom of the timber swings free the timberman drives in his axe, the assistant slacks the rope, and the man with the axe guides the falling stick out upon a roller placed conveniently on the station platform. The rope is then loosened and the timber rolled to the waiting truck. The whole operation is completed in less time than it takes to describe it, and the method is as satisfactory as if it had been devised by an efficiency engineer after elaborate motion studies.

Special Correspondence

NEW YORK

IMPROVED OUTLOOK.—THE COPPER MARKET.—DEFLATION OF THE PORCUPINE BOOM.—THE CALUMET & HECLA MERGER.—PIOCHE.—SALE OF GOLD ROAD MINE.

The various stages of a period of depression are fairly well known to students of business conditions. The present stagnation in general business, undoubtedly more acute in Wall Street than elsewhere, has been passing through the stage where discussion and comment have for the most part been confined to a search for language in which to describe adequately the prevailing condition. It is an extremely hopeful sign that men of large affairs are now taking a sanguine tone in pointing out the fundamentally sound basis on which the business of the country really rests.

New York is more largely interested in copper than in any other branch of mining and the state of the copper market is the index of mining activity in Eastern markets. Copper appears to have touched bottom with something of a rebound. Large sales have been made and estimates of the amount of copper so disposed of have been appearing almost hourly. Amalgamated is said to have sold 80,000,000 lb. at 12¼c., while the Guggenheims, the Phelps-Dodge company, and the Lake companies are said to have sold all the copper for early delivery that they desire to sell. There has been as much market capital made of these sales as possible, and the cleaning up of the metal pressing for sale would be a strong uplift, were it not for the fact that the greater part of the metal sold was for export demand. Domestic consumers continue to stand aloof, as they can afford to do in view of the new production that must come to market. There are some shifts worthy of note in copper circles. It is said that the estate of the late Henry R. Rogers has liquidated its last share of copper stock. It has not been long since Mr. Rogers was looked upon as the dominant factor in copper, and he often bought and sold Amalgamated in ten and twenty thousand lots. Closely connected with the selling of the Rogers holdings is the announcement that the United Metals Selling Co. will no longer hold to an upset price for its copper, but will meet the Guggenheims in open market competition, selling as may seem best according to the prevailing demand. Both of these items mark the retirement of Urban H. Broughton from active participation in enterprises with which he has been for many years associated. The policy of the United Metals has been a strong supporting factor in the copper market, in sustaining the price even when competitors appeared to take away business or when buyers refused to come into the market. Now the company declares it will 'hold the umbrella' no longer. It is believed that the Producers' report for April will show considerable improvement.

Next to copper, the possibilities in Porcupine absorb attention. The wave of enthusiasm which sprang up a month or so ago, has been succeeded by a decidedly chilly atmosphere of suspended judgment. The Eastern press has discouraged all incipient booms in Porcupine, and the boomers are evidently shifting their activities to London, where the press encourages the exploitation of the new goldfield, though the caution is repeatedly given to have nothing to do with any venture offered in London by promoters from the United States.

The Calumet & Hecla merger is apparently indefinitely

MAP SHOWING COPPER REGIONS OF AMERICA.

postponed. The obstructions are increasing. Thomas L. Chadbourne, Jr., son of the late Thomas L. Chadbourne who died at Palm Beach April 18, has taken up the fight begun by his father, and it is understood will demand of the directors permission to make an independent examination of the Calumet & Hecla property. If the examination is to be made it will require considerable time. If the demand is refused, such refusal will undoubtedly be made the basis for further litigation. In the meantime the stock market is suffering and most of the subsidiary companies are selling below the parity of the merger basis. In addition to the fight being waged by Mr. Chadbourne and the Hyams litigation, a number of the Osceola stockholders have applied for a restraining order, which has been issued by the Michigan court, and adds another obstacle to the completion of the merger. The Chadbourne bill, providing for the appraisal of Michigan properties about to be consolidated, was erroneously announced as having passed both houses of the Michigan legislature. As a matter of fact the bill did pass the lower house, and was apparently about to go through the upper house without a hitch, when it was recalled and killed. The tonnage-tax bill, which was aimed at the copper producers by the agricultural interests of the State of Michigan was beaten only after a bitter contest.

The Calumet & Hecla people appear to be somewhat discouraged and say that if the merger had not advanced so far it would be dropped without further effort to complete it.

The merger of the principal properties in the camp of Pioche has been declared off. The stockholders in Nevada-Utah have been hoping that the merger would save the situation. The prospects are now that the attempted consolidation would result in a snarl of litigation.

The deal of the United States Smelting, Refining & Mining Co. for the Gold Road property at Kingman, Arizona, is awaiting the action of the foreign stockholders, most of whom reside in Paris. The examination which has been completed is said to show an ore reserve equal to the price which has been named for the property.

JOHANNESBURG, TRANSVAAL

ANNUAL MEETING OF RAND MINES, LTD.—RESULTS FOR YEAR.—LABOR SCARCITY.—STOPE-DRILLS.—METALLURGICAL ADVANCES.—RESIGNATION OF G. E. WEBBER.—FUTURE PROSPECTS.

The annual meeting of the Rand Mines Ltd. was held here on March 22, R. W. Schumacher presiding. The remarks from the chair were full of weight and interest, for the Rand Mines Ltd. has been accurately described as the barometer of the situation on the Witwatersrand, and the yearly oration of the chairman not only reflects the position at the great gold mines under the company's control, but also gives a concise and accurate view of the status of the gold industry of the Transvaal.

Last year Rand Mines Ltd. earned a net profit of £1,133,548, of which £1,030,354 was derived from dividends on shareholdings in subsidiary undertakings. During 1910 the crushing capacity of these subsidiaries was raised from 4,500,000 tons per annum to 5,112,000, the machinery employed at the end of the year aggregating 1915 stamps and 48 tube-mills. The average grade of the ore sent to the mills during the year was 8.01 dwt. per ton before crushing, and the average actual extraction obtained was 95.98%. Average yields, working costs, and profits on the tonnage-milled basis were as follows:

	Dwt.		
Yield from mills	5.347		
Yield from cyanide works	2.344		
Total	7.691	or £1	12s. 3d.
Working costs:		s.	d.
Mining		12	5
Developing		1	5
Ore reduction		4	7
General		1	7
Total		20	0

The profit per ton was thus 12s. 3d., and this on a basis of 3,134,793 tons crushed gave a total working profit of £2,524,035. In addition to this a further profit of £41,068 was obtained from the re-treatment of dumps and accumulated slime. Mr. Schumacher dealt with many questions and problems in the course of his speech. He analyzed the results obtained at subsidiary mines in detail, showed how a scarcity of labor and the work of reorganization had in some cases retarded operations, and also pointed out the necessity of developing further the use of small machine-drills in stoping. With regard to working conditions on the mines, Mr. Schumacher stated that the Rand Mines, Wernher, Beit & Co.'s, have since 1902 spent nearly one million pounds on improvements and extensions of housing and other accommodation of their employees. In regard to metallurgy, the chairman said that investigations showed that tube-mills could deal to advantage with a much larger and coarser product than had hitherto been supplied. It has been found that by crushing through a 3 or 8-mesh screen stamp-duties can be increased to 20 tons or more per day. The limits of the tube-mill as regards the size or coarseness of the feed are not yet known, but the tendency is to have the product as coarse as possible with due regard to efficiency. This raises a series of questions. Is a stamp-mill the most efficient medium for effecting this comparatively coarse crushing? Can this degree of fineness be economically attained with the type of crushers used for breaking the coarsest material? Can the design of the tube-mills be so improved as to crush an even coarser material than at present? These problems are being studied, and important economies in the cost of construction and in the operating expenses of reduction plants is likely to be soon effected.

In concluding his speech, the chairman made a highly appreciative reference to the work carried out by George E. Webber, who has been general manager of Rand Mines Ltd. since 1896. Mr. Webber is resigning the management of the company, as he wishes to retire on account of his health. Mr. Webber leaves the Rand Mines Ltd. with an aggregate ore reserve in the subsidiary undertakings of over seventeen million tons, and it is of interest to read the retiring general manager's opinion of the prospects of this, the premier gold-mining corporation of the world. Mr. Webber writes: "Your general holdings are on such a sound basis that the financial position of the company as regards present dividend obligations seem unassailable, while the outlook for the comparatively near future gives every promise of a still stronger position."

TORONTO, CANADA

OPENING OF NAVIGATION.—PORCUPINE SHARES.—RESULTS OF EXPLORATION.—RESUMPTION OF POWER SUPPLY.—THE TEMISKAMING MINE.—LAKE OF THE WOODS DISTRICT.

Spring floods are seriously interfering with mining at Porcupine. As it will be some time yet before the lakes are sufficiently cleared of ice to allow of navigation an interval of inactivity is anticipated. A recent estimate gave the number of men at work as 1200, and this is certain to be largely increased when navigation opens. The market for Porcupine issues has lately been quiet, and in place of the general advance anticipated some of the stocks have dropped below the figures at which they were underwritten. Apart from the question of intrinsic value, which can only be decided by further development, the market has been glutted of late by new flotations altogether beyond the absorbing capacity of the market. The latest important issue is the Ontario Gold Fields Development Co., a Bewick-Moreing flotation issued at $5 par, and traded in locally at about $6.25. Hollinger continues well in the lead, selling at about $10. Free gold has been found at the Dobie at the depth of 240 ft. Drilling on the West Dome shows free gold at 224 to 240 ft. Another hole down 170 ft. is through a vein approximately 16 ft. wide carrying gold in paying quantities. A working shaft has been started. The Foley-O'Brien has reached a depth of 150 ft. in the working shaft and will start a cross-cut to the main vein. A new 30-ft. vein has been uncovered at the Dome Extension and is proving rich. Three main working shafts are being sunk. At the Preston East Dome two 50-hp. boilers are in place and the air-drills are almost ready for work. Trenching is being done preparatory to sinking. Six large veins have been found on the Richardson-Shillington properties on Pearl lake, operated by the Jupiter company, with good gold content. Water in the shafts caused a suspension of work for ten days on the Pearl Lake. Steam pumps are now unwatering the mine. The Hollinger has 150 men at work. Driving has been done for 60 ft. on the 200-ft. level, where the vein is 10 ft. wide and shows good ore. The two shafts are connected by an adit at the 100-ft. level where about 1400 ft. of driving has been done. In the cross-cut at this level near No. 1 shaft another vein 6 in. wide has been found. The Swastika is installing additional machinery and will develop to 400 feet.

The difficulty arising from power shortage at Cobalt is over with the breaking of the ice blockade on the northern rivers. The larger mines are again taking compressed air from the Ragged Chutes plant on the Montreal river, and the supply will be normal in a short time. The Temiskaming

is now working at a depth of 575 ft., but the latest reports are not reassuring as to the continuance of high-grade ore at that level. The ore now being taken out is not so good as that on the 500-ft. level. The Rochester will be sunk to 400 ft. as soon as power can be obtained. The Provincial has found rich ore in driving on the 271-ft. level about 40 ft. from the shaft. The vein splits into stringers aggregating about 2 in. wide and running 1500 oz. per ton.

Much interest has been aroused by the gold area of the Lake of the Woods district, in northwestern Ontario by recent rich discoveries in the old mines lately reopened, especially the Ophir and the Mikado. On the former a good find of high-grade ore has been made at the 100-ft. level and a large body of low-grade has also been found. The Mikado is working in good ore at a depth of 480 ft. A number of other properties are being developed. The properties in this region at one time yielded well, but operations were discontinued some twenty years ago on account of a dispute between the Canadian and Ontario governments as to jurisdiction. The Canadian Pacific Prospecting & Mining Co., which was operating the Ophir, held its title from the Dominion, and the Ontario Government took legal proceedings against it. A period of protracted and costly litigation followed, terminating with an appeal to the British Privy Council, and the case dragged on until a few years ago, when it was decided in favor of the Ontario Government. Meanwhile mining industry was at a standstill and the confidence in Canadian enterprises of those who had financed the Canadian Pacific Mining Co. was destroyed. The region is just beginning to recover from the blow.

JOPLIN, MISSOURI

EFFECT OF MEXICAN REVOLUTION IN ZINC DISTRICT.—NEW MINING REGION OPENED AT LAWTON, KANSAS.—LARGEST MILL IN MISSOURI-KANSAS-OKLAHOMA DISTRICT PLANNED.—ZINC AND LEAD GOSSIP.

Forced out of the Mexican market because of the rebellion, the Edgar Zinc Co., one of the heaviest purchasers of Mexican zinc ores, has entered the Joplin field with the result that much of the 13,000 tons of unsold surplus in the bins at the beginning of April has been consumed and prices have been raised. In one week's time the Edgar company purchased somewhat over 2000 tons, more than one-third of the total zinc-ore production of the district, in which almost twenty smelting companies are purchasing ores. Zinc ore is now bringing $36 to $41 per ton on the basis of 60% Zn; while calamine is bringing from $20 to $24 per ton on the basis of 40% Zn. April shipments of zincblende and calamine were unusually heavy, but lead-ore shipments showed a falling off, due to the smelters having stocked up early in the year when prices were hovering around $52 and $54. Lead ore now is bringing $58 to $60 per ton.

A promising new zinc-lead region, which is yet in the development stage, has been discovered at Lawton, Kansas, northwest of Joplin and more than ten miles from the nearest producing mines, and scores of prospectors are flocking there. One mill of 300 tons daily capacity is nearing completion, and is to be operated by the Eastern Lead & Zinc Co. Walter Ragland, former mine inspector of southwest Missouri, is manager. Large bodies of disseminated ore are found at depths of 100 to 200 ft. Among the prominent operators who have met success in other camps of the district and who are helping to open the Lawton camp are Chapman & Lennan, and Ball & Gunning, of Webb City; Howard E. Gray, of Joplin, and many others.

On the newly acquired tract of the American Zinc, Lead & Smelting Co., in the north Webb City district, a mill of 1400 tons daily capacity, which will be the largest in the Missouri-Kansas-Oklahoma district, is planned for a strip of ground upon which extensive drilling has been done. Sheet ore, occurring at 180 and 210 ft., is said to have been thoroughly explored and enough ore shown to be present to warrant the erection of so large a plant. Thorndyke & Co., a leasing company, is erecting a 300-ton plant on the American company's latest lease. Extensive improvements are being made by the American company in other fields, the projected zinc smelter at Collinsville, Illinois, being of especial importance.

Among recent finds is that made by Joe Dillon, a pioneer prospector and miner of the district, who, while 'up against' a temporary run of hard luck, constructed a home-made horse-power drill-rig and with this crude device has put one hole down into good ore and is sinking a second. Unable at first to defray the expense of drilling his lease, Dillon now could command enough money to make his holdings look like a pepper-box. His lease is east of Joplin, and at a depth of 80 ft. he found free 'jack' containing more than 60% Zn, while the drillings show the ore to constitute 30% of the dirt taken out. The prospecting apparatus consists of a bit, resurrected from a junk-yard, a badly patched cable, a hickory sapling, a few pulleys, an eccentric, a whim, and a so-called horse which, from appearances, will soon be soap. The peculiar jerking motion of the sapling beam as it works on the eccentric causes the drill-bit to operate with slow but satisfactory results.

Jealousy on the part of rival operators, Tom Coyne of Webb City, and Jess Short of Joplin, has resulted in a friendly production contest, the loser to give the proceeds

A JOPLIN PROSPECTING RIG.

from the sale of the ore on the day of the contest to charitable institutions. This means a donation of at least $1500. Both are in the rejuvenated Thoms Station camp, several miles north of Joplin. The zinc ore, with some lead, occurs in large pockets and at Short's mine, the Sitting Bull, the dirt up to date has averaged 60% ore as it comes from the ground. The concentrate assays only about 55% Zn, because of the presence of iron sulphide. Coyne's mill-dirt, while not as rich as Short's, produces a concentrate that runs better than 63% Zn. Numerous other companies are opening big mines in the Thoms Station camp. This entire district was drilled years ago, as at that time a few shallow mines had been opened. Invariably the drills were stopped at 100 to 125 ft., for deeper mining at that time was not seriously considered. The recent discoveries that have brought this camp into the limelight again have been made at depths ranging from 150 to 200 ft. In some instances the old shafts had been sunk to within a few feet of the richest ore. As a result the output of the Joplin camp, which includes Thoms Station, has been increased by more than 500,000 tons of zincblende weekly.

At Aurora perhaps more shallow operations are in progress than in any other portion of the district, with the possible exception of Galena, Kansas. Calamine is the principal ore, many of the shallow ores being of exceptionally good quality. Some operators produce only the ore in the rough, screen it, and sell it for $3 to $5 per ton. 'Chatters' purchase this product, mill it, and sell it in turn to the smelters, getting regular market rates. Among the producers that are showing up in good form are the Sphalerite, North Pole, No. 4 Drill Co., and Coleman Bros. Originally a heavy producer of lead ore, Aurora is now growing more important as a zinc producer.

DENVER, COLORADO

Another Side of the Educational Campaign.—The Lost Bullion Gold Mine Case.—Reduced Transportation Rates.—Cripple Creek News.

The campaign to educate investors both in and outside of Colorado to the possibilities of mining in this State is meeting with merited success. Colorado has the mineral resources. But when the prospective investor has been interested in a mining venture, the work is far from completed. There must be some economic basis upon which the buyer and seller can get together. The investor takes all the risk, and naturally he is not going into a project unless he can be reasonably sure of success. The investor must be convinced that the seller of the property is giving him a good chance to make sufficient profit to compensate him for the risk he is taking. There are many good prospects lying idle in Colorado today because the owners want so much for them that there is little prospect of a buyer ever realizing a reasonable profit and the return of the invested capital. These remarks are not made with any intention of 'knocking.' The idea expressed has been impressed on me through years of experience in trying to bring buyers and sellers together. It is comparatively easy to figure out the value of developed ore, and a fair estimate can usually be made on future possibilities. Translating these values, actual and prospective, into terms of present worth is the most difficult part of an engineer's work. Having done this work to the best of his ability, it is rather disconcerting to find that the owner looks upon him as a pessimist bent on robbery, but unless the owner has had the idea of present worth brought to his attention from some outside source he is apt to form just this opinion of the engineer. It is to be hoped that this plea for a little home missionary work in sound finance will not be without avail.

The Lost Bullion Gold Mine case has been reversed by the United States Circuit Court of Appeals. This case attracted considerable attention in August 1907, when the officers of the company were convicted of using the mails to defraud. Nearly a dozen of the principals were sentenced to prison or fined. The prospectus of the company told of the finding of a fabulously rich old Spanish mine in New Mexico. The original owners had been driven off by the Indians and had so carefully concealed the mine openings that the mine had been truly lost. The evidence adduced at the trial tended to show that the so-called extensive workings of the old mine were connected caves in limestone formation. What the new trial will show is hard to say, as the post-office inspectors who handled the case originally are out of the service, and many of the defendants are either dead or have moved away.

The Denver & Rio Grande railroad has announced a concession on its freight rate from Silverton to Durango. Last season the minimum rate was $1.25 per ton on $15 ore. This same rate will hold on all ores up to $18 per ton for the coming season and a large tonnage is anticipated. The management of the Newhouse adit, at Idaho Springs, is doing all in its power to stimulate mining in the territory served. A new schedule provides for a decrease of 20c. per ton in the transportation of ores valued at $6 per ton and less, and a cut of 50% in the charge for compressed air. While these new rates barely pay for the cost of the service with the present output it is expected that a large increase in production will follow.

Cripple Creek operators have broken the record production for March, having shipped 77,836, as against 73,125 tons produced in the preceding month. The drainage tunnel is partly responsible for this large tonnage, but another factor is competition between the mills situated at Colorado City. The United States Reduction & Refining plant has been closed for repairs for a few days, but has now resumed a full capacity. The treatment rate has been restored to the same figures as last September. The El Paso Consolidated Gold Mining Co. has done over 250 ft. of development work on the Fuller cross-cut and the C. K. & N. fissure without materially increasing the flow in the tunnel. The work is being continued to gain some desired information. Later the heading of the drainage tunnel may be advanced. The old-time case of Paul A. Primeau against H. A. Granfield has been settled. Primeau ran a brokerage office in New York during the boom days in Cripple Creek. Granfield acted as his local agent and invested some surplus arising from buying stock for Primeau. The investment was in what proved to be a profitable lease, on the C. K. & N. mine.

LONDON

Mexico Mines and Libel Suit.—Satisfactory Ending.—Seoul Mining Co.—New Stamp-Mill.—Changes Necessary.—Production for 1910.

In writing some weeks ago I recorded the unfortunate contretemps by which the Pearson interests and the French shareholders secured control of the Mexico Mines of El Oro, thus removing the company from the Exploration company group, and calling for the resignation of the chairman, R. T. Bayliss. The reason for this violent capture of control was the refusal of Mr. Bayliss to be a party to the undue booming of the Mexico shares. He considered the quotation too high and also objected to paying too large dividends at a time when it was obvious that money must be spent on shaft repairs and reorganizing the underground work to suit altered conditions. How he was outvoted has been related. What rankled in his breast more than defeat in fair battle was the imputation that he was acting as a bear of the Mexico shares for his own interests. This allegation was made in a letter addressed by S. Pearson & Son to the secretary of the company. Mr. Bayliss referred to the subject at the meeting of shareholders, and stated that never during the course of his career had he ever dealt in shares of companies he was connected with. Those who know Mr. Bayliss are aware of his principles, and did not require his refutation of such an accusation; and, indeed, on any other subject his word is sufficient. However, in the City of London it is always best to meet these imputations with the strongest weapon possible, and accordingly Mr. Bayliss entered action for libel. Pearsons never intended to defend the case, and in fact their representatives at the meeting of shareholders had publicly stated that their letter was not intended to reflect in any way on his personal honor, apparently holding that the manipulation of the share-market for his own purpose came within the legitimate scope of business enterprise on the part of the chairman of a company. When the case came on, the lawyers on the two sides announced that it had been settled out of court, the defendants stating that they did not consider that the letter contained anything reflecting on the plaintiff's honor, but that if the plaintiff considered that any words in it did so, they unreservedly withdrew them and expressed regret that they were used. To an American this action and its method of conduct in court may seem an unnecessary formality, but an Englishman of integrity wishes to have it put on permanent record in the most public and indisputable way that accusations made of unfair dealing were unwarrantable and indefensible.

The progress of the Seoul Mining Co., an American company owning the Suan copper-gold mine in the province of Hwang-Hai, Korea, is watched with considerable interest in England, for the property was originally owned by an English company called the Korea Syndicate. The operations of the English syndicate were not successful, and three years ago Messrs. Colbran and Bostwick took over the concession, agreeing to pay the syndicate 20% of the profits. They formed the present company with a capital of $400,000, under the laws of Maine. A 20-stamp mill was built in 1909 and started on December 1 of that year. Developments continued to be so satisfactory that another 20 stamps were erected in 1910 and started work on December 1. The metallurgical problem has not yet been completely solved, for bismuth interferes with the gold extraction, and the concentrators which follow the stamps do not recover a high percentage of the copper. During 1910, 32,793 tons of ore was sent to the mill; and 707 tons of hand-picked ore and 389 tons of concentrate were shipped to Tacoma.

General Mining News

ALASKA

COOK INLET

The Kenai Star M. Co. has taken over the Longman placers on Palmer creek, near Hope. J. D. Meenach and Nels Peterson are interested.

KETCHIKAN

Word has been received from the Jumbo mine at Sulzer that all the surface improvements have been swept away by a snowslide. Two men were killed and several injured. A launch has been sent to bring the latter in to the hospital.

PRINCE WILLIAM SOUND

Mike Wagner and partners have found good dirt on Eva creek, a tributary coming in on No. 5 Below Left Limit on Ester creek. The dirt goes $2.50 to the square foot of bedrock at the end of their drift. Ed Nelson has purchased a half interest in the Bay View group of three claims, on the west side of Valdez bay, about one-half mile east of Gold creek. The adit on the property of the Hemple Copper M. Co. at Landlock bay is in 700 ft. and has cut a good body of shipping ore. Another adit has been started at a point 800 ft. to the northwest to cut another ore-shoot on the same vein. The Suessdorf & Devinney mine has a 3-ft. vein of good ore and has 200 tons of ore on the dump ready for treatment. The Valdez-Liseum mine is starting a 200-ft. adit. The Alaska-Gold Hill M. Co. has several veins on its property, and one large one shows assays of $19 per ton. The Beaver Dam mine, on the wagon-road, forty miles from Valdez, has been sold to Seward people for $40,000.

THE TANANA

Congress has made an appropriation of $80,000 to be expended during the coming summer on bridging, grading, and repairing the trail from Valdez to Fairbanks. Fifty thousand dollars will be spent on the Seward-Iditarod trail and $20,000 on the Fairbanks-Nome and other trails.

ARIZONA

COCHISE COUNTY

The Calumet & Arizona and the Superior & Pittsburg were consolidated at the annual meeting of the shareholders on April 25. The consolidation increases the capital to 650,000 shares at $10 each and provides for the exchange of three shares of Superior for each share of Calumet. The board of the latter, including H. R. Rea from the Superior, was elected, and immediately proceeded to make a thorough inspection of the properties. W. E. Corey is a member of the board.

GILA COUNTY

(Special Correspondence.)—The fourth unit of the Miami mill is now in operation and the fifth and sixth are expected to start May 15. The saving in the mill is now almost 80% and the concentrate runs 39% copper; by the middle of the month it is expected to reach 42%. The first shipment of concentrate was two 50-ton cars on April 11, and a car is being shipped daily to Cananea. Half the ore supply of the mill will be taken from the stock-piles until they are used up. The Arizona Commercial is just entering the ore recently discovered by diamond-drills at the 1000-ft. level; the north cross-cut from the station at that depth is now 150 ft. to the breast and has passed through about 30 ft. of vein matter. Considerable copper glance as well as oxidized ore of a good grade has been found. Probably the vein at this point will furnish smelting ore, although the aspect of the vein, so far as it has been cut, gives the impression that the bulk of sulphide ore lies below the 1000-ft. level, as indicated by the yellow sulphide encountered just above the 1200-ft. depth by the drill. The shaft is now 1070 ft. deep in the diabase. The winze being sunk from the 700-ft. level is 55 ft. deep, but although it is passing through well mineralized ground it is not thought that ore in any quantity will be found until the winze reaches the spot where the diamond-drill cut it. One of the pumps on the 1000-ft. station is lifting with ease all the water.

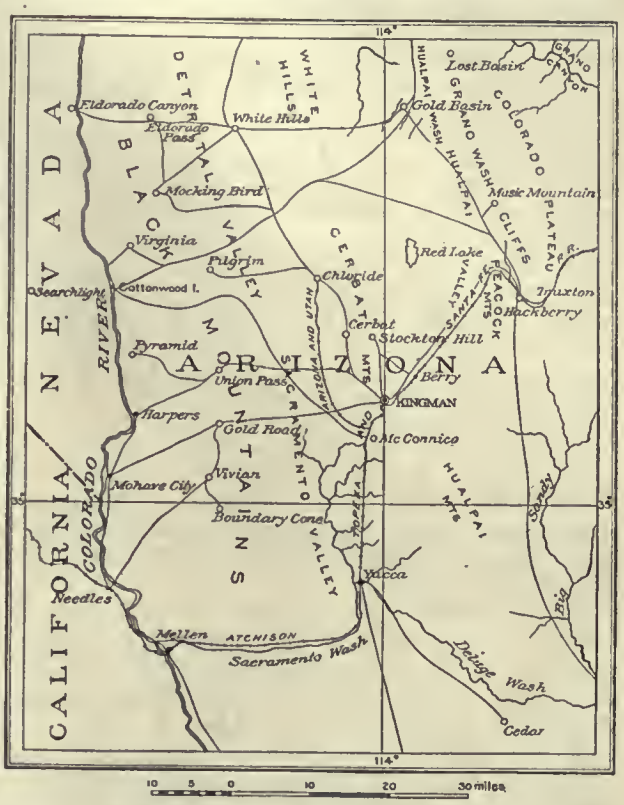
Miami, April 28.

GRAHAM COUNTY

A number of Scotch shareholders in the Arizona Copper Co., whose mines are at Clifton, have made a thorough inspection of the property, and it is reported that extensive improvements will be made.

MOHAVE COUNTY

An 8-day mill-run at the Gold Road mine yielded a bar worth $17,500. It is reported that the sale of this mine is off, but it is actually waiting for the action of the foreign shareholders. The annual meeting of the Tom Reed mine



MOHAVE COUNTY MINING DISTRICTS.

was held recently and the report shows that $250,000 has been distributed to the shareholders and $90,000 is on hand. The new 30-stamp mill has been built from the profits of the operation of the old 10-stamp mill. Charles Grimes is president. The Rainbow mine at Chloride is shipping a small amount of ore. The main shaft is down 240 ft. and it will be sunk 100 ft. more. Plans are being made for the construction of a tramway from the mine to the proposed railway station at Cerbat, near the Tennessee mine. H. M. Bowen has taken an option on the Jamison mine at Layne Springs, and will begin work soon.

YUMA COUNTY

High-grade ore has been found in the bottom of the 196-ft. shaft of the Calzona Mines Co. Two carloads shipped to the Humboldt smelter were said to be worth over $250 per ton. The Hon Mining Co. has been incorporated to work mines in Copper basin. It is reported that a shipment made by the P. & D. Grass Root mines, in the Old Woman mountains, near Milligan, to the Needles smelter, netted $50 per ton.

CALIFORNIA

ELDORADO COUNTY

J. A. Roxburgh has found several nuggets on his fruit ranch near Kelsey and has high hopes of developing a good gold mine. Mr. Chester is putting up a cyanide plant to work the tailing-dump at the old Taylor mine near Georgetown. A large bench deposit has been opened in the Landecker gravel mine that runs $50 to $80 per car.

INYO COUNTY

Keeler is much excited over the rich ore found by R. C.

Troeger in his adit on Cerro Gordo mountain. The ore-zone was found at 3750 ft. and seven veins have been cut, carrying rich stringers of tetrahedrite, the ore assaying as high as $150 per ton. The Cerro Gordo has resumed shipments and 30 tons was sent to the smelter last week, the grade averaging about $40 per ton. Lloyd Skinner, who is in charge, has found a rich lead-silver ore-shoot that is over 5 ft. wide and 50 ft. long, below the 1025-ft. level.

MARIPOSA COUNTY

(Special Correspondence.)—The Merced G. M. Co. of Coulterville will be re-opened by H. P. Dalton, of Oakland, and associates. The property is equipped with a 40-stamp mill of Union Iron Works design, and with hoisting, pumping, and transporting machinery estimated to be worth about $200,000. The consideration for this property is said to be about $500,000. The Malvina mine will be opened first, work to begin about May 15. H. C. Kennedy, of Coulterville, will be manager.

O. R. Morris, of San Francisco, has been awarded the contract to erect the Penon Blanco mill, at a cost, it is said, of $80,000. Grading on the site has been started. The San Joaquin Light & Power Co. has extended its line to Bullion hill. The Quartz mountain and Bullion hill mines will be among those to derive advantage from the cheap power. The Bondurant properties, recently taken over by Stockton capitalists, have been re-opened as the Bondoro group of mines. A 40-hp. boiler is being installed to be in readiness for the starting of the 10-stamp mill on June 1. George H. Gerken is superintendent.

Coulterville, April 26.

MONO COUNTY

The Tri-Metal cyanide plant which was erected to re-work the old Benton mill tailing, will start on May 1. Lessees are finding good ore in the old Borasea mine on Blind Spring hill.

NEVADA COUNTY

The W. F. of M. finds much difficulty in compelling delinquent members to pay their dues, and a meeting was held at Grass Valley on Sunday to consider ways and means of compelling the delinquents to pay up.

(Special Correspondence.)—A. H. Winn, representing the California Title & Insurance Co., is negotiating the purchase of the Pennsylvania-W. Y. O. D. mines. The price asked by the latter is $500,000. The Pennsylvania has been a steady producer for 25 years, averaging $10,000 to $18,000 per month at present, from a 12-in. vein in granodiorite. The W. Y. O. D. passed into the hands of the Pennsylvania company some years ago as the result of a lawsuit.

On the 350-ft. level of the Cassidy Con. the vein has been intersected. It averages 40 in. wide. Assays run $10 to $20 per ton. Sinking will be continued until the 500-ft. point is reached, and it is probable that a mill will be erected before the end of summer. The Cassidy adjoins the Empire and was re-opened about a year ago, after a long period of inactivity. Until the present owners took charge, the property had not been developed to any extent. F. C. Longe is manager. Sinking at the Brunswick is progressing rapidly, and it is expected that the company will be in a position to produce through the new shaft before the close of 1911.

Grass Valley, April 29.

SHASTA COUNTY

The Vulcan Copper Co. has set up a motor compressor and is erecting tanks preparatory to beginning diamond-drilling. The surface work already done has exposed small bodies of high-grade ore. The Vulcan is next to the Balaklala.

SIERRA COUNTY

Twenty stamps are now at work in the Sierra Buttes mill, and most of the ore being crushed is high grade. It is reported that a stamp-mill will be erected on the San Luis property, near Sierra City, during the summer. The Gold Bluff middle fork flume, which was carried away by a snow and earth slide, is being reconstructed.

SUTTER COUNTY

The Natomas Con. has bought 160 acres of the old Jopson place, near Nicolaus, from W. F. Sperry.

TUOLUMNE COUNTY

The Sivori brothers are driving from the bottom of a 50-ft. shaft at their claim at Cherokee, near Tuolumne, and will shortly begin stoping to surface. The vein is 2 ft. wide and it is estimated will mill $50 per ton. It is the intention of the operators to install a hoist and a small mill in the near future. Twenty of the 60 stamps at the Jumper are in operation, and between 80 and 100 tons of ore is milled daily. About 80 men are employed. High-grade ore is being extracted from a new vein on the property of the United Mines Corporation, near Tuolumne, by Richard Rowe, the discoverer, who, since securing a lease, has been driving an adit to open the orebody. The vein is in the Dead Horse claim and is 18 in. wide. Several tons of the ore has been taken to a nearby mill for treatment.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Goodale & Co., leasing through raise No. 10 on the Aetna vein at the Capital mine, have found a 2-ft. body of $125 ore, and Eade & Co., leasing through raise No. 6, have sold 40 tons of concentrate that netted $44 per ton, and 85 oz. of amalgam was taken off the plates.——An 8-in. streak of $35 ore has been uncovered in the drift on the Key West vein.——The Gambetta mine on Republican mountain will ship an average of 20 carloads of zinc ore each month.——The compressor plant at the Sidney adit will be started May 1.——An 18-in. streak of $35 ore has been found in the drift on the Welsh vein, Leavenworth mountain.

Georgetown, April 26.

LAKE COUNTY (LEADVILLE)

(Special Correspondence.)—Among our important mills the Leadville District M. & M. Co. is treating 50 tons per day in a wet concentration mill, and the American Zinc Extraction Co. is using magnetic separation preceded by roasting. They are shipping 100 tons of concentrate per day. The sulphide shipments still exceed the carbonate and silicate of zinc in amount and importance. The average daily production of zinc ore at Leadville is about as follows:

	Tons per day.
Zinc carbonate ore	350
Zinc sulphide ore	500
Zinc sulphide concentrate (from mill-ore)	100
Lead ore (over 5% lead)	300
Gold, silver, or copper ore	500

Leadville, April 25.

SAN JUAN DISTRICT

The Camp Bird is working a 12-ft. orebody to the west of the workings on the Coronado vein. The George Crawford companies, formed to take over the Yankee Girl, Genesee-Vanderbilt, Red Mountain, Gold Lion, Blue Bell, and the Joker adit, are to be reorganized with a reduced capital. H. Y. Russel is in charge. The Revenue mine is increasing its output and has 180 men at work in its mine and mill. There are 17,000 sacks of concentrate stored at the mill waiting for the roads to open. The rumor that the Camp Bird will take over the Revenue property persists. It is expected that the Mono-Baltic smelter will be blown in within a few months. Now that the railroad is clear of snow the Gold King at Gladstone has started its 300-ton mill. It is reported that the mill of the Sunnyside will be enlarged.

SUMMIT COUNTY

(Special Correspondence.)—The Shoe Basin mines at Argentine have cut the Peruvian vein at 1036 ft. in their adit and have driven it 30 ft. without finding the hanging wall. In the Colorado-Toledo mine driving is being done in both directions on the vein found at 2650 ft. in the adit, and 6 to 18 in. of good ore is being found. The Penn mill is making good progress and it is expected that the two 6-ft. Chilean mills will be ready in June. It seems likely that this will be a prosperous season in the Montezuma and

Argentine districts; the possibility that the automatic electric railroad may be built soon is doing much to stimulate interest.

Argentine, April 28.

TELLER COUNTY (CRIPPLE CREEK)

The summary of Cripple Creek production for April is as follows:

Plant.	Tons.	Average value.	Gross bullion value.
Golden Cycle (Colorado City)	27,700	$21.25	$588,625.00
U. S. R. & R. (Colorado City)	14,010	21.50	307,215.00
Portland (Colorado City)	10,000	20.00	200,000.00
Portland (Cripple Creek district)	10,504	3.28	34,453.12
Wild Horse	1,000	4.00	4,000.00
Stratton's Independence	10,512	3.08	32,336.96
Smelters (Denver and Pueblo)	4,110	65.00	267,150.00
Totals	77,836	$18.40	$1,433,780.08

The dividends paid during the month amount to $142,500, distributed thus: Portland G. M. Co., $60,000; Vindicator Con. G. M. Co., $45,000; Elkton Con. M. & M. Co., $37,500. Two good ore-shoots have been found by lessees at the 150 and 250-ft. levels of the Beacon shaft. Good ore is being taken out of the Stratton's Independence by lessees. In the South Burns on Bull hill, a new ore-shoot has been found in the northern extension of the Shurtloff vein. A 15-drill belt-driven compressor has been ordered by the Isabella Mines Co. Rich ore has been found in the Peggy, on Gold hill.

IDAHO

BOISE COUNTY

(Special Correspondence.)—The Moline Mining Co., E. F. Blain, manager, began operations on April 1. The 5-ft. Risdon dredge, built in 1905, is handling from 1100 to 1400 yd. per day, at an average cost of a little more than 4c. per yard. Three 8-hour shifts of two men each, together with one dredge-master and a roustabout, constitute the crew. Steam-power is used. The 100-hp. boiler is amply sufficient for operating the driving, pump, and headline engines and the hoisting and swinging winches. Wood is used; the consumption is six cords of 4-ft. material; the cost delivered at the dredge being $3.25 per cord.

W. F. Hiatt and T. Halley have 200 acres of ground from 6 to 40 ft. deep, averaging 19c. per yard, which they are working with one No. 2 Hendy giant. The amount of water available is only 200 in., under moderate head. Their active season began March 20 and will end about June 1. A little more than 15,000 yd. will be handled.

Placerville, April 27.

(Special Correspondence.)—The dredge under construction by the Yuba Construction Co. for the Boston-Idaho Gold Dredging Co. will be put in commission about May 1. Practically everything is completed. This is the largest dredge to be built in Idaho and one of the second largest built by the California company. The actual capacity of the buckets is 14.6 cu. ft., each of which weighs 4200 lb. The rated capacity is 10,000 cu. yd. per day. Power is supplied from the Boston-Idaho plant on the Payette river, the current on the main line having a voltage of 19,000, which is transformed to 2200 volts for use on the boat. A total of 810 hp. is required for the eight meters with which the dredge is equipped. The length of the hull is 125 ft.; its draught is 8 ft. 6 in.; approximately 250,000 ft. of lumber and 330 tons of metal were used in its construction; it will dig 35 ft. below water-level; and the table area is more than 6000 sq. ft. The ground this dredge will work averages 22 ft. in depth, several hundred feet in width, six miles in length, and, according to L. E. Aubrey, 17c. per yard.

Idaho City, April 27.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The Butte mines produced, in April, about 21,156,150 lb. of copper. The output of ore and production of copper daily and for the month, were:

Companies.	Daily, tons ore.	Month, tons ore.	Daily, lb. copper.	Month, lb. copper.
Anaconda	3,525	105,700	215,025	6,450,750
Butte & Boston	430	12,900	25,800	774,000
Parrot	370	11,100	22,940	688,200
Washoe	360	10,800	21,960	658,800
Trenton	400	12,000	23,600	708,000
Original	650	19,500	40,950	1,228,500
North Butte	890	26,700	54,290	1,628,700
Coalition	900	27,000	60,300	1,809,000
Tuolumne	100	3,000	9,000	270,000
Boston & Montana	3,110	93,300	199,040	5,971,200
East Butte	380	11,400	32,300	969,000
Totals	11,115	333,400	705,205	21,156,150

While the Copper Producers Association for the past several months has showed a continued increase in the surplus and at the same time an increase in the consumption, it may be interesting to draw attention to the fact that compared with a year ago the Amalgamated mines produced about 1,000,000 pounds less in March of this year and over 5,000,000 pounds less than in March two years ago. When the production at present is compared with that of two years ago, it will be seen that the curtailment is between 4,000,000 and 5,000,000 pounds per month, which means a big reduction for the mines of the company, but when it is considered that very extensive improvements have been going on for nearly the whole of the two years, it will be readily seen that the payroll has not been cut down to anything like what might appear on the surface. In fact, it would be found, if the books of the company were examined, that the money paid out in improvements, repairs, new machinery, and labor has been much greater by a very considerable amount than any previous two years in the history of the combined mines of the district. A large amount of this money expended will, of course, well repay the company, as it means reduced costs and larger production when the time comes for the operation of the mines to their full capacity.

Mr. Stone, superintendent of the Butte-Alex Scott, is very much elated over the showing the mine has been making since the first of the year, and is confident of even a better showing during the months of April, May, and June than in January, February, and March when the property turned out 1,200,000 pounds of copper which ran 8.75% copper. From the earnings all the operating expenses are being met, and the cost of development, and, besides, a goodly sum is going into the treasury each month. Development work is going ahead on the 500, 1200, 1400, 1500, and 1600-ft. levels, and some good ore is being blocked out. Just now the company is sending on an average of about one car of ore each day to the smelter, and it is expected that in a few weeks this amount will be considerably increased.

The Tuolumne company has a little less than 300 ft. more to go to bring the shaft down to a depth of 2000 ft. A station has been cut at the 1600 and others will be built at the 1800 and 2000-ft. levels. Cross-cutting is now in progress north and south from the 1600-ft. level, and the south vein is expected to be reached in a short time. The shipments of 100 tons per day to the smelter are being maintained in addition to the development work and sinking. The ore averages 9% copper, and from this more than sufficient money is derived to pay all expenses.

Butte, April 28.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Combination Fraction company's annual report shows a net operating loss for the past fiscal year of $38,447.57, and the company has suspended operations and has leased its ground for a period of 15 months from April 1. The C. O. D. Con. company, under the management of L. K. Koontz, is developing on the 600-ft. level from the Sills shaft on the Gold Bar claim, and two lessees are working from the same point to explore ground north, west, and southwest. It is regarded as certain that the lessees working the original Gold Bar work-

ings and who are now sinking the main shaft to greater depth, will erect a 50-ton reduction plant in the near future. The Yellow Tiger is in good milling ore on the 700-ft. level. A. A. Redmond will begin extensive work on a group in the southern part of the district on June 1. Lessees continue developing on the Atlanta, Blue Bell, Commonwealth, Merger Mines, Booth, Oro, Nighthawk, Daisy, Black Butte, and at other points in the district.

Goldfield, April 25.

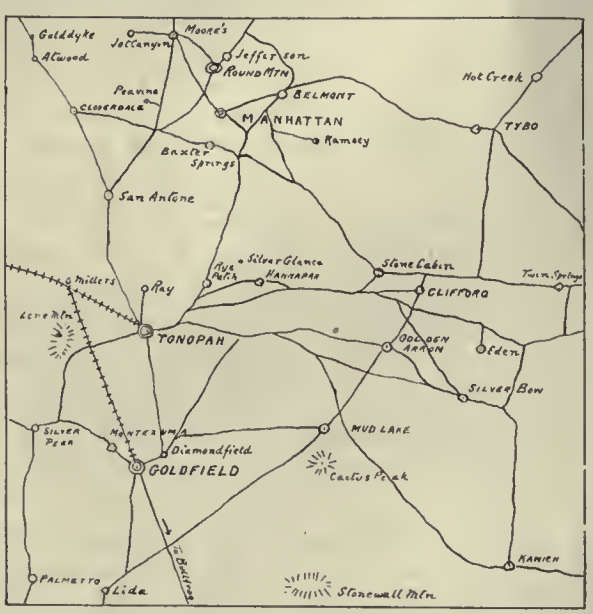
HUMBOLDT COUNTY

(Special Correspondence.)—The Utah National M. Co. has leased 28 acres on the Snowden estate, adjoining the National Mines holdings. A 500-ft. shaft has been started. At the National Mines an approximate depth of 800 ft. has been attained. The orebodies continue to show strength and value. A streak of quartz 1 to 2 in. wide has been opened on the Adamson-Turner property on the north slope of Winnemucca mountain that at times runs 30 to 50% gold, according to the miners. The vein in the Scorpion, Barrett Springs district, has been opened by a crosscut from the 50-ft. level of the shaft. Prospecting in the National and Barret Springs districts is exceptionally active.

Winnemucca, April 21.

NYE COUNTY

(Special Correspondence.)—The Tonopah Mining Co. is preparing to work a portion of its holdings through the



PART OF NEVADA.

Desert Queen shaft, recently abandoned by the Belmont company. The ore-washer at the West End is in operation and teams are hauling shipping ore to the depot. The mill recently purchased from the Midway Milling Co. is being remodeled, and foundations installed for new machinery which has been purchased in San Francisco. The shaft of the North Star is being placed in excellent condition, and work will soon be in progress on the 900 and 1250-ft. levels.

Tonopah, April 25.

WHITE PINE COUNTY

(Special Correspondence.)—During the past few weeks the Ely Consolidated company, through its Zack mine, adjoining the property of the Nevada Con. on the south, has opened what promises to be a large body of good ore. A considerable body of similar ore was opened on the 400-ft. level of the Zack mine last year. The shaft reached the 500-ft. level about January 1 last, when a drift was started to the south and a cross-cut to the west. The cross-cut almost immediately opened ore averaging from 6 to 8% in copper value, and continued through the same grade of ore for a distance of 27 ft., where limestone was struck. The cross-cut was continued in limestone for a distance of 18 ft. where another orebody was encountered. The cross-cut has now been continued in this body of ore for a distance of 55 ft., and is still in ore. The general average of the ore, according to samples taken by James Quinn, the manager of the property, is about 6% copper and 30c. gold per ton, not counting the high-grade ore, of which there is a considerable amount in evidence averaging more than 20%. The south drift on this level has been continued for more than 300 ft., the last half of which is all in porphyry carrying occasional stringers of good ore. From present indications the Ely Consolidated will soon have one of the big copper mines of the camp.

Ely, April 25.

OREGON

(Telegraphic Correspondence.)—The initial payment of $200,000 was made yesterday on the Rainbow mine in Mormon basin, by the U. S. S. & R. Co. The total purchase price is $750,000, the largest amount ever paid for a mine in Oregon.

Baker, May 3.

JACKSON COUNTY

Chicago investors have leased 2100 acres of the holdings of the Cascade Coal Co. between the 401 Ranch and the summit of Roxy Ann, and the work of pumping out the slope has begun. There are three seams, of 9, 7, and 5 ft. The coal has been tested and found of superior quality. Only the 7-ft. seam will be worked at first.

JOSEPHINE COUNTY

Rich ore has been found by the lessees of the Higgins mine, 20 miles northwest of Kerby, on the divide between Rancheria and Baby Foot creeks. The gold is in friable material which is being washed in sluices. Much excitement has been created and exaggerated reports have been given out, but the existence of rich ore is indisputable.

UTAH

TOOELE COUNTY

(Special Correspondence.)—The Gold Chain has taxed its present hoisting plant to the limit during the past two weeks and has sent out 10 carloads each week. The work of sinking the Yankee shaft to the water-level has commenced. The shaft is now down to 1700 ft., and it is expected that the sulphide zone will be reached in about 100 to 300 ft. more. Articles of incorporation have been filed for the Dragon Consolidated, which takes over the Dragon and the Governor. Work on the Utah Con. of Tintic has been resumed, the intention being to extend the new tunnel. The new find on the Eagle and Blue Bell is opening up well. A drift of 80 ft. and a raise of the same length has not found the walls. Indications are that this is the north continuation of the vein from which the Victoria has been shipping some very rich ore recently. So far work has been confined to development and an attempt to explore the deposit and ascertain its extent. The old California mine, which is being operated under lease by the Virginia Mining Co., has cut two veins of good shipping ore and is now stocking, awaiting the time that the roads improve, so that the ore can be hauled out. Indications are that steady shipments can be kept up. During the month of March the South Utah milled 23,972 tons of ore, an average of practically 800 tons per day. From this ore there was produced 2301 tons of concentrate which yielded 300,000 lb. of copper.

Tintic, April 29.

SALT LAKE COUNTY

(Special Correspondence.)—What was expected to be a lively contest for the control of the Utah Consolidated with a strong chance of a change in the management, did not materialize at the annual stockholders' meeting, and the old board is retained in control. U. H. Broughton, the president, has issued a long explanatory statement as to mine conditions, and includes a statement that since the true condition first became known last fall, over 14,000 ft. of development work has been done and new orebodies in unexplored territory opened.

The receiver of the North Utah has mailed to the stock-

holders of the company an announcement of his intention of selling the property at public auction in the latter part of May, unless the stockholders in the meantime take steps to reorganize and pay off certain outstanding debts.

Bingham, April 26.

WASHINGTON

FERRY COUNTY

The First Thought mine at Orient has shipped some ore that averages more than $2000 in gold per ton. The source of this ore is a shoot opened recently in the main workings at a depth of 500 ft. Knowledge of conditions in the locality was obtained by diamond-drill exploration in the eastern part of the property.

CANADA

BRITISH COLUMBIA

The Kootenay Central railway will give an outlet for the iron ores on Fenwick mountain, near Bull River falls, which, though of much promise, are as yet undeveloped. Good ore has been found in the Big Tunnel near Greenwood. The Consolidated M. & S. Co. will increase its shipments to the Trail smelter to 900 to 950 tons per day. The smelter receipts for March from the Le Roi No. 2, Ltd., were $34,289.

DAWSON

The Dawson Power & Light Co. is shipping 300 tons of heavy machinery to its plant at Coal creek, with the expectation of mining coal on a large scale and using it to generate electric power to be used on the Guggenheim dredges as well as in lighting Dawson. Treadgold will employ 1000 men this summer in dredging and hydraulicking on Dominion, Sulphur, and Quartz creeks, and is expending $250,000 in erecting a power and water supply plant on the north fork of the Klondike. It is reported that the Yukon Gold Co. has bought a large part of Gold Run creek. Extensive preparations are being made on all sides for the summer's work.

ONTARIO

The March production of the Nipissing was estimated at a value of $185,332. The Bishop Silver Mines, at Calcite lake, near Gowganda, has cut its vein at 190 ft. The Coniagas M. Co. has declared another dividend of 6% with 3% extra, payable on May 1, making the total paid to date 53%. The Cobalt Provincial has found a rich shoot of ore about 40 ft. from the shaft on the 270-ft. level. The Harris Maxwell M. Co. of Larder Lake is in litigation with the Goldfields of Larder Lake Co. over the option which the latter had on the former. The claims of the Haileybury Silver Co. in Deloro township, near the Philadelphia, have been sold to M. T. Rowland of Arizona.

PORCUPINE

A water-supply for Porcupine is being secured from the Porcupine river to supplement the wells. Excellent progress is being made on the T. & N. O. railroad into Porcupine; steel has been laid as far as the Frederickhouse river and the bridge there completed. Grading has been started north from South Porcupine toward the Dome. The Imperial Porcupine has finished erecting its plant and has begun work again. Work on the Porcupine Apex, adjoining the West Dome, has commenced. The British-American Power Co. will begin construction work in June on its power-plant at Waiwaitan Falls on the Mattagami river. Since power was delivered in Cobalt nine months after beginning construction work there, Porcupine hopes for an equally speedy supply of electric power.

MEXICO

CHIHUAHUA

The Culantrella property, in San Francisco del Oro, has been re-examined by B. V. Gordon, P. B. Butler, and Santiago Cunningham, and it is reported that M. H. Briggs and associates, of London, will re-open this property, which was closed down about four years ago. Juan Almanzan is finding good ore in the new shaft sunk in the foot-wall of Terrenates property, which is next to the Los Muertes on the Veta Colorada vein. High-grade ore has also been found in the Santa Rosalia shaft of the Iguana which has been leased to P. B. Butler. Mr. Butler is also driving a 1200-metre adit along the vein on the San Francisco del Oro. Work has been resumed in the San Cristobal at Parral. The new electric hoist is in operation. The National Mines & Smelter Co. will repair the old mill of the Lustre Mining Co. at Magistral. The Alvarado M. & M. Co. has bought the properties of the Hidalgo Mining Co. for $500,000.

HIDALGO

The new cyanide plant of the Purissima Grande Hacienda Co. has turned out about 40 bars of bullion and is working very well. R. A. Brown has charge of the enlargement of the Guerrero mill of the Real del Monte y Pachuca company, which has just finished constructing Pachuca tanks at its Loreto mill and is now erecting them at the Guerrero plant.

SONORA

(Special Correspondence.)—The Creston Colorada Mining Co. has treated 42,260 tons of ore and 6600 tons of slime since January 1, 1911. The Creston mine produced 34,633 tons of ore; the rest came from the Colorada. Most of the ore is from surface workings. Extensive work is being carried on in both the Creston and the Colorada mines. The company has discontinued exploration on the Verde property, which was under option and was explored by a long cross-cut from the Creston shaft. At the Creston mine new ore-bins are being erected. A pneumatic hoist raises the ore 12 ft. to a landing, where it is dumped over the grizzlies, the fine falling direct to the bin, while the coarse goes to a gyratory-crusher and from that into the bin. Formerly the ore was dumped directly into the crushers, but the fine ore caused much trouble and lessened the capacity of the crusher. Several buildings have been removed and the surface stripped near the Creston shaft to furnish access to several large orebodies near the surface which have recently been disclosed by development. The Butters mill and cyanide plant, leased to the Creston Colorada company, has been connected with the Creston mine by a new tramway and is running satisfactorily. The Creston Colorada Mining Co. is a subsidiary of the Mines Company of America, of New York, and is operated by that company. M. F. Perry is manager; he is also associated with the Charles Butters interests in this camp and other parts of the country, and has recently left Minas Prietas for Salvador, Central America.

Minas Prietas, April 24.

News from Naeozari states that the Moctezuma Copper Co. has continued at work throughout the revolutionary troubles without molestation. A full supply of workmen has always been available, as the employees of the company are not subject to military draft, and the pacifically inclined have sought work for this reason. The Naeozari railroad was shut down for some days while in the hands of the rebels, but is now in operation again. The Agua Buena, 8 miles from the Pilares mine of the Moctezuma company, is shipping 2 cars of 3600-oz. silver ore per month, and W. C. Humphrey is shipping a car per week of 100-oz. ore from his mine 20 miles south of Naeozari.

PERU

A company headed by M. F. Porras, ex-minister of finance, is making a detailed examination of the Sayapullo copper-silver mines and the Huayday coal mines. It is proposed to build a railway, hydraulic power-plant, and a 500-ton smelter. The Montebello Oreeo Mining Co., which is operating 12 miles northeast of the Santo Domingo mine of the Inca Mining Co. in Sandia province, has obtained such good results in its small stamp-mill that it will increase its capital by £20,000 and will build a 30-ton cyanide plant. The San Luis mine in the San Buenventura district in Canta province has shipped copper as good as 50%; the Federico el Grande and La Palanca are also shipping on a smaller scale. The 150-ton blast-furnace erected last autumn at the Fernadini smelting plant at Huaraucaca, has been in successful operation ever since.

Company Reports

ORIENTAL CON. MINING CO.

The report of this company, whose mines are in the Unsan district, north of Seoul, Korea, shows that during 1910 320,707 tons of ore was milled with a gross yield of $1,749,468 worth of gold and a resulting profit of $623,676. Dividends paid during the year represented 11½% on the capital. The company has in its employ 60 Americans and Europeans, 150 Japanese, 500 Chinese, and 5000 Koreans. The ore reserve is 838,250 tons, valued at $3,948,475.

NORTH STAR MINES COMPANY

The report of this company for the year ended December 31, 1910, shows that during that period the company produced gold to the value of $1,232,933.96, at a total cost for operation and development of $555,860.03, leaving a profit on the year's operations of $677,073.93. Of this $7148.08 was applied to the improvement account, $36,485.82 to the purchase of property, and $575,000 was disbursed in the payment of dividends amounting to 23% of the capital stock ($2,500,000). The ore milled amounted to 90,110 tons, of an average value of $13.683 per ton, the total cost for operation and development being $6.169 per ton. The cost of development was $0.556 and the cost of concentration and cyaniding the concentrate was $6.34 per ton. The financial statement for the period since May 1884 shows that $510,770.37 has been expended in the purchase of additional property, $554,526 has been invested, and the cash on hand amounts to $403,471.88. The income from interest and dividends was $44,631.05 during 1910. The dividends which have been paid during the life of the company amount to $3,061,988.90. The development work done during the past year has increased the amount of ore reserve, but the exact tonnage has not been estimated. The sum of $52,500 has been advanced toward the preliminary expense of a hydro-electric power-plant project. The financial position of the company is thus seen to be excellent.

LA ROSE CON. MINES CO.

The report covers a period of seven months from June 1 to December 31, 1910, owing to changing the date of ending fiscal year. It shows that 2,569,905 oz. of silver was produced at a cost of 19.11c. per ounce, and sold at an average price of 53.955c. per ounce, the profit being 65% of the gross value, compared with 56% during the preceding year. Dividends were paid amounting to $449,588, which corresponds to 10.28% per year on the book value of the capital stock. The ore reserve at the end of the period is given as 86,758 tons, estimated to contain silver to the net value of $2,000,000, or $^4/_{15}$ of the authorized capital. The accounts are so presented that it is difficult to obtain any clear understanding of them, beyond that the La Rose Con. Mines Co. has an authorized capital of 1,500,000 shares of a par value of $5 each, of which 1,498,627 shares are outstanding. The assets of the company consist of the entire capital stock of the La Rose Mines, Ltd., The Lawson Mines, Ltd., Violet Mining Co., and 7262 shares of University Mines, Ltd., in which latter company La Rose Mines, Ltd., also holds 89,998 shares. La Rose Mines, Ltd., paid dividends amounting to $475,000 during the period under review and has a surplus on hand of $917,803. University Mines, Ltd., made a loss during the 7-month period of $463, making its total deficit $13,436. No balance sheets are given for The Lawson Mines, Ltd., or the Violet Mining Co. The balance sheet of the La Rose Consolidated Mines Co. shows a surplus of $13,361.

ROUND MOUNTAIN MINING CO.

The report covers a period of eleven months, ended February 28, 1911. During this period 36,252 tons was milled of a value of $9.31 per ton, of which $8.34 was recovered, or 89.64%. The total cost for mining and milling was $5.61 per ton, to which the expenses of litigation added 56c. per ton, a total of $6.17, which is reduced to $6.02 by miscellaneous earnings of 15c. per ton. One foot of development work has been done for every 5.56 tons milled, by which the ore reserve has been increased 10.14 tons, or approximately two tons developed for each ton milled. The ore reserve at the end of the period under review is given as 111,928 tons, of an estimated gross value of $1,007,350. The authorized capital of the company is 1,000,000 shares of a par value of $1 each, of which 868,966 shares have been issued. The net earnings during the period were $84,313, dividends 9 and 10 were paid, amounting to $69,322, leaving undivided profits on hand at the end of the period of $184,006; the cash on hand and bullion in transit amounts to $60,658. The results of exploration and development have been most satisfactory; the cross-cut which is being driven toward the Morrin vein is within 250 ft. of the seam, and has intersected four other orebodies, from 3 to 12 ft. in width, from which good ore has been obtained. The placer ground belonging to the company has been leased and a substantial profit is expected from this source during the ensuing year. An additional ten inches of water-supply has been secured. Additions have been made to the mill equipment which are expected to increase its capacity by one-fourth. It is not planned to pay additional dividends until the expiration of this year.

NIPISSING MINES CO.

The report of this company for the year ended December 31, 1910, shows that 5,548,659.56 oz. of silver was produced at a cost of 14.72c. per ounce, yielding a profit of $2,167,103, or 72.6% of the gross value. Of this $2,100,000 was paid in dividends, or at the rate of 35% per annum on the par value of the stock of the Nipissing Mines Co., Ltd., leaving a surplus of $8381.10. The Nipissing Mining Co. has a surplus of $952,798.96. The estimated ore reserve is 6,552,880 tons, of a gross value of $3,276,440, with silver at 50c. per ounce. This does not include the mill-rock on the dumps and in the mines. The reserve was slightly greater at the end of the year than at the beginning. During the year the cost of production has been reduced 1.68c. per ounce.

The shipments during 1910 were:

	Dry tons	Net value per ton	Net value	Per cent of total net value
High-grade ore	1531.792	$1,317.51	$2,018,152.21	73.6
Low-grade siliceous ore	4834.3315	88.34	427,069.68	15.6
Concentrates	319.12	456.90	145,805.27	5.3
Nuggets	13.6865	11,054.25	151,294.07	5.5
Total	6698.93		$2,742,321.23	100.0

The cost of production is analyzed thus:

	Cents per oz.
Mining, including development	8.87
Concentrator	0.83
Depreciation	0.58
Selling	5.03
General expense	0.36
	15.67
Less rents and interest	0.95
Total cost of production	14.72

The allowance here made for depreciation is somewhat scanty, even on the comparatively small capitalization of the Nipissing Mining Co., and the Nipissing Mines Co., which is capitalized for 24 times the book value of the Nipissing Mining Co., makes no further allowance for depreciation. The total value of the dividends so far paid by the Nipissing Mining Co. is $6,012,500, and the net value of the ore marketed has been $9,438,908. A small plant, designed by Chas. Butters, has recently been erected to test on a working scale a process for the treatment of the high-grade ore in order to recover a higher percentage of the value than is paid by the smelting company.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

TABLES FOR THE DETERMINATION OF MINERALS BY MEANS OF THEIR PHYSICAL PROPERTIES, OCCURRENCES, AND ASSOCIATES. By E. H. Kraus and Walter Fred Hunt. Pp. 254; index. McGraw-Hill Book Co., New York. Price $2. For sale by the *Mining and Scientific Press.*

Ability to make rapid and sure determination of minerals in the field is an accomplishment of great value. Naturally, there is no royal road to it, and only years of experience lead to perfection. There are, however, short cuts to approximate determinations, and for many purposes these are entirely adequate. It is also possible, by use of tables to accurately identify most of the common minerals by simple means. The tables prepared some twenty years ago by W. O. Crosby have long been out of print, and except for Frazer and Brown's 'Tables' no satisfactory substitute has been available. The new work by Kraus and Hunt is built on the same general plan. Minerals are grouped by lustre and color, and further subdivided according to streak and hardness. The key is necessarily somewhat artificial, just as was that of the old Gray's 'Botany,' but, as in the latter case, it is simple and effective. The book is one that will be particularly useful to those who have but meagre laboratory facilities and whose use for mineralogy is incidental.

H. F. B.

OUT OF AFRICA. By Thomas Lane Carter. Pp. 288. Neale Publishing Co., New York. Price $1.50. For sale by the *Mining and Scientific Press.*

This book of short stories is one of the by-products of mining, and in these days when conservationists hold the centre of the stage, all good engineers are careful of by-products. Mr. Carter's work has called him to many of the uttermost parts of the earth when interesting things were happening. Evidently, however, he is one of those lucky individuals who has an 'experiencing nature', so that interesting things always happen to him. In these stories he tells some of the incidents that do not go into the report an engineer makes to his principals, however much they may have entered into his work. Ah Sin makes real to us some of the difficulties Rand managers had to face while Chinese were employed, and Rub Tub will recall some campfire companion to many an engineer. Prince Chala and Tung Uhrr are of Africa alone, and for that we may be thankful. That Mr. Carter put them in his book is also a matter for gratitude, as we would rather meet them there than in thicket or compound. The stories are simple, direct, and interesting. Some day we hope Mr. Carter will give us a companion volume telling what he has seen and heard in Central America. In the land where, according to O. Henry, Confederate currency will still do in a pinch, he should have found good material.

H. F. B.

METALLURGY OF THE COMMON METALS, GOLD, SILVER, IRON, COPPER, LEAD, AND ZINC. By Leonard S. Austin. Third Edition. Pp. 521; Ill., index. *Mining and Scientific Press*, San Francisco. *The Mining Magazine*, London, 1911. Price $4.

The third edition of this well-known work, which has just come from the press, includes much new matter, particularly with regard to sintering, reverberatory smelting of copper ores, basic converters, and cost of plant and equipment. In addition, the material has been rearranged and systematically and carefully revised. While the general scope and character of the book remain unchanged, much of the material in it has been entirely rewritten. A number of illustrations have been re-drawn, and others added. All these things greatly improve an already good book, and will add to its usefulness. The book remains essentially a discussion of the common principles of smelting, with illustration drawn from practice, and is well adapted to general use as a text. Mr. Austin is to be congratulated on the demand for his work which compels the issuing of a third edition.

Another of the excellent studies of technology of the clay-working industries, made by the Ohio Survey; written in collaboration with Edward Orton, Jr., and owing much to his inspiration and careful editorial work.

The following publications have recently been issued by the United States Geological Survey:

'Annual Report of the Director of the United States Geological Survey for the year ended June 30, 1910', George Otis Smith, 130 pp.; 'Mineral Products of the United States for the years 1900-1909', 20 by 30 in.; 'Well-Drilling Methods', Isaiah Bowman, 1911, 139 pp., ill.; 'Advance Chapters from Contributions to Economic Geology', Part II, 'Mineral Fuels', by Charles Butts, M. R. Campbell, E. G. Woodruff, C. T. Lupton, J. S. Diller, M. A. Pishel, H. E. Gregory, and A. C. Veatch, Bull 143-B, 1911, 163 pp., ill., maps; 'The State Geological Surveys of the United States', compiled under the direction of C. W. Hayes, 1911, 177 pp.; 'Results of Spirit-Leveling in Delaware, District of Columbia, Maryland, and Virginia, 1896 to 1909, inclusive', R. B. Marshall, Chief Geographer, pp. 74, Washington, 1910; advance chapters from 'Mineral Resources of the United States, 1909'; 'Production of Graphite in 1909', Edson S. Bastin, pp. 134; 'Production of Copper in 1909', B. S. Butler, pp. 34; 'Manufacture of Coke in 1909', Edward W. Parker, pp. 57; 'Production of Sulphur and Pyrite in 1909', W. C. Phalen, pp. 14; 'Production of Peat in 1909', Charles A. Davis, pp. 6; 'Production of Salt and Bromine in 1909', W. C. Phalen, pp. 25; 'Lead in 1909, Smelter Production', C. E. Siebenthal, pp. 25; 'Production of Coal in 1909', Edward W. Parker, pp. 195; 'Zinc and Cadmium in 1909, Smelter Production', C. E. Siebenthal, pp. 24; 'Production of Monazite in 1910', Douglas B. Sterrett, pp. 6.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF COAL LAND HELD BY ADVERSE POSSESSION

A person in the adverse possession of mineral lands, but without paper title, and before such adverse possession had continued for the statutory period, conveyed the coal under such land for a valuable consideration to a third person. While such a conveyanee would convey no title as against the legal owner, yet where the grantor subsequently acquired a valid title by a continuance of such adverse possession for the statutory period, he would then hold the legal title to the coal in trust for the grantee to whom it had been previously deeded and he could then be compelled to execute a valid conveyance for the coal.

Jordan *v.* Chambers, (Penn.) 75 Atlantic 956. Jan. 1910.

POSSESSION OF SURFACE AFTER SEVERANCE OF MINERALS

The right to go upon land to mine and drill for gas and oil is not defeated by covenants for quiet possession in the conveyanee of such land where the gas and oil are excepted, as covenants in a deed that are plainly intended to defend that which has been granted are only co-extensive with the grant, and mere possession of the surface of land is not possession of the oil and gas in place, where there has been a severance of title. Where oil and gas have been severed in title from that of the land under which they are, they are not in possession of the owner of the surface unless he takes actual physical possession of them, as by drilling wells.

Kiser *v.* McLean, (W. Va.) 67 Southeastern 725. March 1910.

WHAT CONSTITUTES A MINING LEASE

A lease of a tract of land for a term of ten years by which the lessee agreed to mine the same and sell the minerals produced, and pay the lessor a percentage of the proceeds as royalty, was a mining lease which gave the lessee no property rights in the ore under the land excepting such as he should mine and sell within the terms of the lease, and such lessee could not maintain an action against a trespasser who mined and removed ore from the premises during the stated term for the recovery of the value of the ore taken, but was entitled to recover damages only to the extent of the actual injury.

Providence Mining & Milling Co. *v.* Nicholson, 178 Federal 29. Feb. 1910.

CONSTRUCTION OF LEASE OF MINE—EXCLUSION OF LESSEE

The owner of a placer-mining claim leased the same to another for a term of years with the right to work the same and take mineral therefrom, paying the lessor a percentage of its value as its royalty during the entire term. The lease expressly provided that time was of its essence, and that the lessee should at once enter upon and work and mine the claim steadily and continually during the mining seasons, and that the lessee should do the necessary representation, and should keep a true account of all clean-ups. Before the expiration of the first year the lessor wrongfully excluded the lessee from the claim and prevented him from working it during the entire remainder of the term. In an action by the lessee for an injunction and damages, the United States District Court of Alaska held that the lease, in addition to being a demise of the mining claim for the term stated, also vested the lessee with the right to become the owner of the mineral therein on condition that it be extracted and converted into personalty during such term, and having wrongfully prevented the lessee from complying with such condition, the lessor thereby waived or estopped himself from exercising the right of excluding the lessee from the claim until the expiration of the term, and until he had a reasonable time to extract the ore he had contracted to purchase. It was also held that a court of equity had power to protect the lessee by injunction where the act of the lessor would result in irreparable injury.

Halla *v.* Rogers, 176 Federal 709. Feb. 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. H. ELLIOTT is in San Francisco.

W. A. SCOTT is at Spokane, Washington.

F. G. FORESHAW is temporarily in London.

S. F. SHAW has returned to New York from London.

J. PARKE CHANNING has returned to New York from Arizona.

B. B. LAWRENCE has left New York for some weeks in the West.

E. M. HAMILTON has gone to England for a three months vacation.

ALBERT BURCH has returned to San Francisco from Goldfield, Nevada.

W. S. NOYES has returned to San Francisco from Texas and Colorado.

VICTOR E. TULL has gone to the Tubal-Cain mine, in Washington, for the summer.

EDWARD M. MCILVAIN has been elected president of the Universal Vanadium Company.

F. W. BRADLEY will leave San Francisco May 13 to spend the summer in Idaho and Alaska.

J. MALCOLM MACLAREN has gone to Porcupine, Ontario, from which place he will go to London.

RUFUS M. BAGG has been elected professor of geology in Lawrence University, Appleton, Wisconsin.

W. G. ANDERSON is now with the Negociacion Minera La Fe y Anexas, at Guadalupe, Zacatecas, Mexico.

DESAIX B. MYERS will be at Chloride, Arizona, for the next thirty days engaged in mine examination.

A. D. FOOTE has been in southern California and is in San Francisco recovering from an attack of neuritis.

C. COLCOCK JONES has removed his office from the Henne building to 1001 Trust & Savings building, Los Angeles.

F. L. SIZER is acting manager at the Balaklala smelter as well as mine, E. B. BRADEN being now general manager.

MARK R. LAMB is manager for the Allis-Chalmers Co. in South America and has established his office at Santiago, Chile.

H. W. EDMONDSON, for the past five years general superintendent for the Rio Plata Mining Co., has resigned, and has been succeeded by A. H. PRIOR, formerly cyanide superintendent.

COURTENAY DE KALB has been made a member of the Committee on Explosives of the Eighth International Congress of Applied Chemistry, which will meet at Washington, September 1912.

H. R. HOLBROOK, formerly of the Balaklala Consolidated Copper Co., Coram, California, has accepted a position as chief chemist for the Mexican-American Smelting & Refining Co., at Guaymas, Mexico.

HENRY R. COBLEIGH has resigned as mechanical editor of *The Iron Age*, which position he has held for the last seven years, to take charge of advertising and publicity of the International Steam Pump Co., with an office at 115 Broadway, New York City.

THE SAN FRANCISCO SECTION of the Mining and Metallurgical Society of America met following dinner at Techau's Tavern, May 1. Messrs. S. B. Christy, C. W. Merrill, F. W. Bradley, J. B. Keating, A. D. Foote, Douglas Waterman, W. S. Noyes, T. T. Read, B. B. Meek, and H. F. Bain were present. The subject of mine inspection was discussed.

ON THURSDAY, MAY 4, 1911, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 164 of $81,750. This makes the total amount of dividends paid $12,701,850.

Market Reports

LOCAL METAL PRICES.

San Francisco, May 4.

Antimony	12—12¾c	Quicksilver (flask)	46.50
Electrolytic Copper	14—15¼c	Tin	45—46½c
Pig Lead	4.75—5.70c	Spelter	7—7¾c

Zinc dust, 1400 lb. casks, per 100 lb., small lots $9.50—9.75; large $7.50—8.50
